Aminophylline in Treatment of Diseases of Coronary Artery.—Statements in medical literature that aminophylline is effective in reducing the number and severity of attacks in disease of the coronary artery were reported. The referee felt that the evidence is not sufficient to justify any change in the therapeutic status of the product. The Council concurred.

Sulfapyridine.—The Council gave further consideration to sulfapyridine and endorsed the reports of the referees that sulfapyridine be accepted for inclusion in New and Nonofficial Remedies (for description, see THE JOURNAL, May 6, p. 1831). The topics discussed under this heading included the name, toxic reactions, estimated dosages, and reports of and the reason for the present high prices of this product.

Immune Globulin.—The Council voted that necessary steps should be taken for reinvestigation of this product with relationship to the matter of the name, to increased uses and to other points that are of importance, including a report on the various purified fractions of the globulin as related to its actions.

Therapeutic Research.—The Council voted that the Committee on Therapeutic Research be thanked formally for its painstaking effort and for the active productivity of the work which it fosters. A concise report of the work of the Committee on Therapeutic Research appears in the annual Reports of Officers, THE JOURNAL, April 8, p. 1380.

Acquisition of Pharmaceutical Concerns by Patent Medicine Interests.—The Council gave further attention to the question of acquisition of pharmaceutical concerns by patent medicine interests. Several examples were discussed but no action was taken. The Council decided however to continue its previous policy, namely, to be very watchful of companies acquired by nostrum interests or closely associated financially with nostrum interests. In those instances in which the Council has information that the best interests of either the public or the medical profession are being jeopardized by a house under such control and having Council-accepted products, immediate action will be taken, particularly in relation to the application of rule 11 to the firms concerned.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

MERCUPURIN.—An aqueous solution containing molar equivalent quantities of the sodium salt of β-methoxy-γ-hydroxymer curi-propylamide of trimethyl cyclopentane, dicarboxylic acid and of theophylline. (The mercurated organic acid is the same as that of which mercurin-N. N. R. is the partial sodium salt. Its specific name is N(γ-hydroxymercuri-β-methoxy) propyl-d-α-camphoramic acid and its structure is given under mercurin). Evidence is given that the theophylline in mercupurin is chemically combined with the mercurial.

Actions and Uses.—Mercupurin is a potent diuretic. It is perhaps less toxic and more active than the purine-free mercurial diuretics. It has been demonstrated that when theophylline is combined with the mercurial, sloughs and venous thrombosis occur with less frequency and severity. Clinical experiments suggested that the presence of theophylline enhances the rate and completeness of absorption, so that the drug is effective and well tolerated by intramuscular as well as intravenous administration. Studies by a number of investigators give indication that Mercupurin is an efficient diuretic. Supplementary administration of acidic salts, such as ammonium chloride, tends to increase the diuresis.

Mercupurin is used to remove excess fluid in edema of congestive heart failure, nephrosis, and cirrhosis of the liver with ascites. It is contraindicated in advanced chronic nephritis and acute renal disease. Care should be taken not to restrict the intake of sodium chloride too drastically, as copious diuresis may give rise to the symptoms associated with hypochloremia.

Dosage.—Mercupurin is supplied in a concentration of 10 per cent (weight/volume) with respect to the sodium salt of the mercurated organic acid and 3.53 per cent with respect to anhydrous theophylline. Each cubic centimeter of mercupurin represents 39 mg. of mercury in non-ionizable form.

Manufactured by Chinoin Laboratories, *Ujpesta, Hungary (Campbell Products, Inc., New York, N. Y., distributor).* U. S. patent 2,116,872 (May 10, 1938; expires 1935). U. S. trademark No. 315,683.

Ampoules Mercupurin, 1 cc.: Each ampule contains 1.1 cc. of mercupurin

Ampoules Mercupurin, 2 cc.: Each ampule contains 2.2 cc. of mercupurin

Mercupurin is a nearly colorless, odorless, bitter tasting aqueous solution whose *pH* lies between 8 5 and 9.0. The specific gravity of the ampule solution is not less than 1 068 nor more than 1 072 at 25 C. The index of refraction at 25 C. for the D line of sodium is 1 3550 (0 0002). The observed optical rotation of the ampule solution is $\alpha = -4\ 5$ (±0 1) when measured in a 200 mm. tube using a sodium lamp.

Transfer 5 cc. of the ampule solution, accurately measured, to a tared beaker and evaporate the solution to dryness over phosphorus pentoxide in a vacuum desiccator: the total dry residue is not less than 135 nor more than 145 mg. per cubic centimeter. Acidify 5 cc of the ampule solution, accurately measured, with 1 cc of concentrated sulfuric acid, carefully evaporate the excess liquid and incinerate in an electric muffle furnace to constant weight using 900 C. as the end temperature for not more than ten minutes the amount of sodium sulfate is not less than 13 nor more than 15 mg per cubic centimeter. Test for free mercuric and other heavy metal ions, sulfates, halides and arsenic as described under mercurin (which see) using 2 cc. of ampule solution Decompose about 10 cc. of ampule solution with hydrogen sulfide as described under mercurin the same crystalline product is obtained, namely N allyl d-α camphoramic acid, m p. 158 C.

Determine nitrogen by the Pregl micro Kjeldahl procedure. each cubic centimeter of mercupurin contains not less than 13 nor more than 17 mg. of nitrogen Pipette 5 cc. of the ampule solution into a platinum dish and determine the mercury content as described under mercurin (which see) each cubic centimeter contains not less than 38 nor more than 40 mg. of mercury. Dilute 5 cc. of mercupurin, accurately measured, with 15 cc. of water, add 5 cc. of 10 per cent ammonium hydroxide and 6 cc of a 10 per cent solution of silver nitrate. Heat gently on the water bath until the precipitate coagulates. Filter, wash with hot water, and dissolve the precipitate in 10 cc. of 10 per cent nitric acid Dilute to 100 cc. and titrate with 0 1 normal ammonium thiocyanate solution using two drops of a saturated solution of *ferric ammonium sulfate* as indicator 1 cc of 0 1 normal ammonium thiocyanate solution is equivalent to 18 0 mg of anhydrous theophylline. Mercupurin contains not less than 34 nor more than 37 mg. of anhydrous theophylline per cubic centimeter

IODOBISMITOL WITH SALIGENIN (See New and Nonofficial Remedies, 1938, p. 151).

Ampoules Iodobismitol with Saligenin, 2 cc · Each ampule contains from 0 115 to 0 133 Gm of sodium iodobismuthite (equivalent to 0 024 to 0 027 Gm. metallic bismuth) and from 0 318 to 0 258 Gm of sodium iodide dissolved in propylene glycol containing 4 per cent saligenin and 0 1 per cent glacial acetic acid.

Iodobismitol with Saligenin, 50 cc. Bottle · Each 2 cc. contains from 0 115 to 0 133 Gm of sodium iodobismuthite (equivalent to 0 024 to 0 027 Gm. of metallic bismuth) and from 0 318 to 0 258 Gm of sodium iodide dissolved in propylene glycol containing 4 per cent saligenin and 0 1 per cent glacial acetic acid

Manufactured by Cutter Laboratories, Berkeley, Calif., by license of Stanford University. U. S patent 1,890,508 (Dec 13, 1932, expires 1949) and 1,927,210 (Sept. 19, 1933, expires 1950). No U. S. trademark.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

FOULDS' EGG ALPHABETS

Manufacturer—The Foulds Milling Company, Libertyville, Ill.

Description—Noodles in the shapes of letters of the alphabet, prepared from durum flour, egg yolk, water and salt.

Manufacture.—Durum flour, egg yolk, salt and water are mixed and kneaded under corrugated steel rolls, run through dough breaks (rollers) and forced through dies to form the desired shapes, dried and packaged.

Analysis (submitted by manufacturer).—Moisture 10 2%, total solids 89.8%, ash (salt free) 0 7%, sodium chloride (NaCl) 1 1%, fat (ether extract) 5.3%, protein (N × 6 25) 15.3%, lipoid phosphoric acid (dry basis) (P_2O_5) 0.13%, estimated egg solids on the moisture-free basis 6 6%, carbohydrates (by difference) 67.4.

Calories.—3 8 per gram; 108 per ounce.

CARIBBEAN BRAND STRAINED BANANAS

Manufacturer.—Caribbean Canning Company, Inc, 1332 Whitney Building, New Orleans.

Description.—Canned, strained, ripe banana.

Manufacture.—Green bananas are stored in a dark humid atmosphere, first at 20 C. and later at 23.9 C. until the desired degree of ripeness is developed. This is indicated by the odor of the fruit and by the complete disappearance of green color and the appearance of flakes of brown on the deep yellow skin. The ripe fruit is peeled, mechanically sliced, dipped in sugar syrup to prevent discoloration, drained, strained and packed into cans. The filled cans are heated for five minutes at 100 C., sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 74.5%, total solids 25 5%, ash 0.6%, fat (ether extract) 0.7%, protein (N × 6 25) 1.3%, crude fiber 0.4%, carbohydrate other than crude fiber (by difference) 22 2%, reducing sugars as invert 7.7%, sucrose (copper reduction method) 12 6%, starch (by difference) 1.9%, acidity as malic 0 25%, *pH* 4 88.

Calories.—1 0 per gram; 28.4 per ounce.

N B C BRAN

Manufacturer.—The National Biscuit Company, New York.

Description.—Milled wheat bran; flavored with sucrose, malt extract, salt and water extract of prunes.

Manufacture.—Wheat bran, which has been run through a high-speed hammermill, is mixed with water, sucrose, prune concentrate, malt extract and salt, cooked in a revolving steam pressure cooker, ground and run through forming machines and a screen scalper to form "nuggets," which are cooled, dried, toasted and packaged.

Analysis (submitted by manufacturer).—Moisture 2.7%, total solids 97.3%, ash 6.4%, fat (ether extract) 2.1%, protein (N × 6.31) 12 0%, crude fiber 8 8%, carbohydrates other than crude fiber (by difference) 68 0%, reducing sugars (as dextrose) 2.03%, sucrose 12.5%, iron (Fe) 0 018%, phosphorus (P) 1.36%.

Calories.—3 39 per gram; 96 per ounce.

Vitamins.—Approximately 1 5 international units of vitamin B_1 per gram.

(1) DAIRY DISTRIBUTERS BRAND EVAPORATED MILK

(2) DAIRY DISTRIBUTERS BRAND VITAMIN D EVAPORATED MILK

Manufacturer.—Watertown Milk Cooperative, Watertown, Wis.

Distributor.—Dairy Distributers, Inc, Milwaukee, a wholly owned subsidiary of the Watertown Milk Company.

Description.—(1) Canned unsweetened evaporated milk. (2) Canned unsweetened evaporated milk fortified by the addition of 325 U. S. P. vitamin D units from Vitex Concentrate per 14½ ounce can.

Manufacture.—Whole milk is carefully inspected and tested at the company plant by state and company inspectors before acceptance. The milk is preheated and filtered Vitex Vitamin D Concentrate to the extent of 325 U. S P. units per 14½ ounce can of the finished evaporated milk is added for the vitamin D milk only. The milk then is evaporated under vacuum, homogenized, cooled, standardized to meet government requirements, filled into cans, sealed and sterilized.

Analyses (submitted by manufacturer).—(1) Moisture 74 1%, total solids 25.9%, ash 1.6%, fat 7.8%, protein (N × 6 38) 7.8%, lactose (by difference) 8 7%, total acidity as lactic 0 3%. (2) Moisture 74 0%, total solids 26 0%, ash 1.6%, fat 7 8%, protein (N × 6 38) 7 8%, lactose (by difference) 8 8%, total acidity as lactic 0 3%

Calories.—(1) and (2) 1.4 per gram; 39.8 per ounce.

CRADLE BABY BRAND STRAINED AND SEEDLESS BLACK RASPBERRY JAM

Manufacturer.—Glaser, Crandell Company, Chicago.

Description.—Canned strained black raspberry jam sweetened with sucrose. The jam may contain small amounts of added acid and/or pectin.

Manufacture.—Black raspberries from Michigan are handled as described for Cradle Baby Brand Strained and Seedless Grape Jam (THE JOURNAL, April 8, 1939, p. 1343).

Analysis (submitted by manufacturer).—Moisture 31.3%, total solids 68.7%, water insoluble solids 0 4%, water soluble solids 68 3%, ash 0 3%, protein (N × 6 25) 0 4%, crude fiber 0 1%, carbohydrates other than crude fiber (by difference) 67.1%, acidity 0.8%.

Calories.—2.70 per gram; 77 per ounce.

THE CASE OF BRINKLEY VS. FISHBEIN

PROCEEDINGS OF A LIBEL SUIT BASED ON AN ARTICLE PUBLISHED IN *HYGEIA*

(Concluded from page 2153)

DEPOSITION OF LESLIE DYE CONN

The deposition of Leslie Dye Conn indicates that he is a resident of Little Rock and that he was graduated from Vanderbilt University School of Medicine in 1907, having previously had three years at Gate City Medical College, Texarkana, Arkansas, in 1901, 1902 and 1903. He was licensed to practice in Arkansas and Oklahoma in 1903, and in Texas in 1913. He was employed by Dr. Brinkley in Del Rio to do physical examinations, and he is now employed in Little Rock doing rechecks on the patients. On cross examination, he stated that complete records are kept of the patients and that about 90 per cent of the patients have shown improvement. It was his opinion that the operations were, in general, successful.

TESTIMONY OF C. B. WARDLOW

C. B. Wardlow testified that he lives in Del Rio, Texas, and is in the ranch business, managing a wool house, and that the reputation of Brinkley was good. On cross examination, it was brought out that he is in partnership with Brinkley.

TESTIMONY OF F. M. ROSE

F. M. Rose stated that he is in the ranch business and has practiced dentistry for fourteen years, and that the reputation of Brinkley is good.

TESTIMONY OF ORVILLE BARNES CHANDLER

Orville Barnes Chandler stated that he is a physician, living in Little Rock, Ark., and working in the Brinkley Hospital. The testimony proceeded:

Q.—In what capacity? *A.*—As physician working in the building in charge of the x-ray and laboratory work and also I am doing the postoperative surgical dressing, checking out patients and advising them what their diet should be after leaving and the medications that are necessary.

Q.—Now, Doctor, let's get what your medical education, what medical education you have had, please, sir? *A.*—Well, I had five years in Vanderbilt University with the degree of Doctor of Medicine on the 14th day of June 1916.

Q.—And then what other studies, if any, have you had subsequent to that time? *A.*—Well, following my graduation I took my internship in Vassar Hospital, Poughkeepsie, New York. That was an eighteen months internship, and I served fourteen months of it and quit the internship and went in the army; I was called as First Lieutenant in the Medical Corps of the army. I went to Fort Riley and had my training there, squads east and west, and from there I was assigned as examiner in x-ray in that camp, and after examining all of the officers and men that claimed x-ray experience and turning in a report on their examinations I was sent to New York, the Cornell School of Military Roentgenology for further instruction as an assistant instructor myself. From there—

Q.—Doctor, tell us what roentgenology is, please, sir, explain that to the jury? *A.*—Well, every one knows what x-rays are, at least knows of them. The x-ray was discovered by Conrad Roentgen of Wurzburg, Bavaria, in 1895 or '96. The medical profession, in order to pay him courtesy, the courtesy that was due him for his scientific work, called it the roengen ray instead of x-ray, so roentgenology is purely and simply a discourse on x-ray.

Q.—All right, go ahead, Doctor, and tell us what further studies or experience you have had? *A.*—I went into the Louisville base hospital at Camp Taylor, Kentucky, as x-ray man in the base hospital, x-ray department, along with others; served there from April until the 1st of September and then from there I was sent to North Carolina and worked there along with Stephens and Moschcowitz, who were two of a committee of three from the surgeon general's office to study empyema, and their x-ray man was ordered away and I was ordered to take his place. We worked there until we cleaned up the empyema cases and then flu broke out and I took charge over the base hospital at Camp Dodge, commencing work on the 4th of October. I stayed there until the 19th of the next July, through the flu epidemic and the gradual decline of the size of the hospital. Then they ordered me from Camp Dodge to Fort McPherson, Georgia, to help take care of those that were coming back. I stayed there from the 21st of July until about the 1st of October, I don't remember the exact date of the order now, but it was around that time, and we were ordered, they ordered me to Hampton, Virginia, to the Old Soldiers' Hospital, which had been turned into a hospital for shell shocks. I was there about a month and ordered to Governors Island for discharge.

Q.—You then received your discharge from the army? *A.*—Yes.

Q.—Now, then, Doctor, since that time have you had any special occasion for study in any clinics or elsewhere? *A.*—Well, I had had so much x-ray work in the army service I figured I would follow that in civil life. I went back to Des Moines, where my family was, and made arrangements for office space and bought an x-ray machine from the Victor x-ray people of Chicago, to be delivered as soon as they could fill the order. I then went back to New York for postgraduate work in skin and cancer work, because I figured I would need it in days to come.

Q.—Now, Doctor, then did you or not continuously from that time until the time you went with Dr. Brinkley engage in the practice of your profession as a physician and surgeon? *A.*—I have been in medical practice every day from that period all along.

Q.—Yes, sir. *A.*—With the exception of about, well, November and December and about half of January, when I first came to Texas I was hanging around San Antonio waiting for the report from Washington to get back, and I was finally informed that I was crowding the age limit too much and the war college had ruled against me on account of age, in regard to my getting back in the army, and then I had to get out and start digging for myself in private life. I started on the 18th of January in South Texas in the general practice.

Q.—Then when was it that you went with Dr. Brinkley? *A.*—Well, that was about, it will be three years the 6th of this coming April.

Q.—Then in April of 1936 was that, Doctor? *A.*—It will be. It was the 6th of April, 1936, that I commenced working for him.

Q.—And, now, tell us, Doctor, what societies or organizations you have been a member of in the past and explain just what those are? *A.*—Well, I have been a member of the North American Radiological Society, a member of the American Medical Association, both the state and county societies, while I was in the Twin Cities. I was a member of the Twin Cities Urinological Society. Those sections where I was I was hooked up with the medical men wherever I was working.

Q.—What do you mean by the Twin Cities, Doctor? *A.*—Minneapolis and St. Paul.

Q.—Was that a society composed of urinologists? *A.*—Not all urinologists, but men interested in urinology.

Q.—Now, then, Doctor, what has been your work and the nature of your work since you have been with Dr. Brinkley, please? *A.*—I was hired by Dr. Brinkley to do his x-ray work and was asked if I would be willing to help out some with the other work if I wasn't overworked in the x-ray department. And I was immediately assigned to do surgical dressings, which I have continued on through. I still have charge of the x-ray work, which I read the plates and make diagnoses and fluoroscopic work. I do that myself. I take care of the diagnoses work, but I don't do the technical work of making the plates. I supervise it.

Q.—Is all of the laboratory work, including the x-ray and the fluoroscopic work and the pathological work done under your supervision? *A.*—Well, I am normally in charge of the laboratory. They have a technician that is a well qualified young fellow that does the technical work and looks after the tests and everything of that kind himself.

Q.—Who is that, please? *A.*—Mr. Kirschberg.

Q.—You mean with reference to the pathology? *A.*—He looks after the clinical and pathological work, and the only time that I am called in is perhaps when he wants me to O. K. his findings on pathological tissue or something like that.

Q.—Now, Doctor, tell us how the hospital is equipped for doing that sort of work? *A.*—Well, we have modern equipment, the latest type of Westinghouse shockproof units in the hospital where I am.

Q.—Is all of that, during the time that you have been with Dr. Brinkley has all of that equipment been kept up to the best standard possible? *A.*—The equipment that I am working with or have in my hands now was bought new when we opened the hospital in Little Rock. The instruments that I worked with at first here in the Roswell Hotel were shipped to Little Rock later and put in the Country Club Hospital, and that way I have an entirely new unit to work with now.

Q.—But was the equipment which was here in the hospital here of the best type available? *A.*—A Victor diagnostic outfit in good shape, I kept it that way. If anything was needed I added to it in the way of accessories and things like that if they were needed.

Q.—Has Dr. Brinkley given any instructions with reference to any new equipment as it may be needed or any new type or changes which may come out from time to time in the type of equipment you have occasion to deal with in your work? *A.*—He told me he wanted me to keep my laboratory up to date and he has never so far refused to get anything I asked for in the way of new equipment or new accessories.

Q.—Were those his instructions from the first time you went with him? *A.*—That has been my understanding right along.

Q.—Have you or not during the time that you have been with Dr. Brinkley had occasion to observe and examine the patients who come there to the hospital? *A.*—Certainly.

Q.—Doctor, have you or not had occasion to observe and know their condition when they came there? *A.*—I have examined the patients, I was the only examiner in the Little Rock Hospital for the first month of the hospital's existence.

Q.—And did you or not also make examinations here at Del Rio? *A.*—Nothing; only the x-ray is all I had anything to do with here.

Q.—And have you had opportunity to examine the patients upon their discharge from the hospital after their operations? *A.*—I check them all out.

Q.—I will ask you to state, Doctor, from your experience with and observation of the patients there whether or not the operation for prostatic trouble which is done by Dr. Brinkley or under his supervision is or not, in your opinion, beneficial to the patients? *A.*—Seeing the patients as they go out, hearing their statements and noting the size of their prostate and condition of it, comparing it with what the record shows they had when they came in, I would have to say there was a greater portion of them showed some improvement.

Q.—Then is or not, in your opinion, the operation beneficial to the patient? *A.*—Well, I should say so if that is the only thing they have had to get that improvement.

Q.—Have you or not also, Doctor, had occasion to examine the patients on return, on their returns at subsequent times? *A.*—Rechecks I have had a few, not many, because most of that work went out to the other hospital.

Q.—But you have had some occasion to make examinations for patients who returned for rechecks? *A.*—Yes, sir.

Q.—In your opinion, Doctor, is the operation generally successful? *A.*—Well, as far as I can see it is. There are certain types of conditions that it takes time, and at the end of seven days we can't—no one could expect to see a prostate that was 2 or 3 inches in diameter shrink up to its normal size in seven days' time unless it had been just a swollen prostate.

Q.—Well, such as you have seen on recheck? *A.*—You see, a person who comes in with three plus or three minus, a three plus or three minus prostate, a good large prostate that is boggy, more or less soft, swollen as it were, it may decrease quite a bit within a week's time. By the end of a year perhaps it is back to normal.

CROSS EXAMINATION

By Mr. Reynolds:

Q.—Dr. Chandler, as I understand it, now, you are doing just surgical dressing and then reading x-rays, is that it? *A.*—That is part of it; I am just generally checking out the patients and giving them their instructions to go home on.

Q.—Is it you who determines whether the patient is ready to leave the hospital? *A.*—Mainly; I notice any change, and if I don't feel they are in shape to be checked out I call attention of that to Dr. Osburn, and he is final on it.

Q.—How long are the patients generally there now? *A.*—Usually figure one week's time.

Q.—What types of incisions are you now dressing? *A.*—Skin incisions.

Q.—Where are they? *A.*—In the front part of the scrotum and one on the other side.

Q.—And what is the length of them? *A.*—After the skin is drawn up it is, perhaps, an inch to inch and a half.

Q.—Have you ever seen Dr. Brinkley perform his prostate operation? *A.*—No, sir, not close enough to tell anything about it; I pass through the room.

Q.—Has he ever told you completely what it is? *A.*—No, sir; I am not interested in that part of it in anyway.

Q.—Then, you really don't know what kind of treatment is being given to the patient so far as his operation is concerned? *A.*—Underneath the skin. I have treated the incisions after they were sewed up.

Q.—But you don't know the nature of the operation itself from first hand knowledge? *A.*—Not first hand, seeing or helping or anything of that kind; I couldn't tell you the details of the operation.

Q.—And you don't make any of the diagnoses, do you? *A.*—No, sir. I simply report what I find on the x-ray picture.

Q.—How many x-ray pictures a week do you imagine you read? *A.*—Right now?

Q.—Yes, sir, now? *A.*—Well, it is hard to say; perhaps, in rush weeks it would be thirty, forty or fifty a day.

Q.—Now, when a person comes in there for treatment do you always x-ray them irrespective of what they are there for? *A.*—The bladder area, yes, sir.

Q.—How many x-ray shots do you make? *A.*—Make one, drain the bladder, refill it with sodium iodide solution and make a second one as a routine.

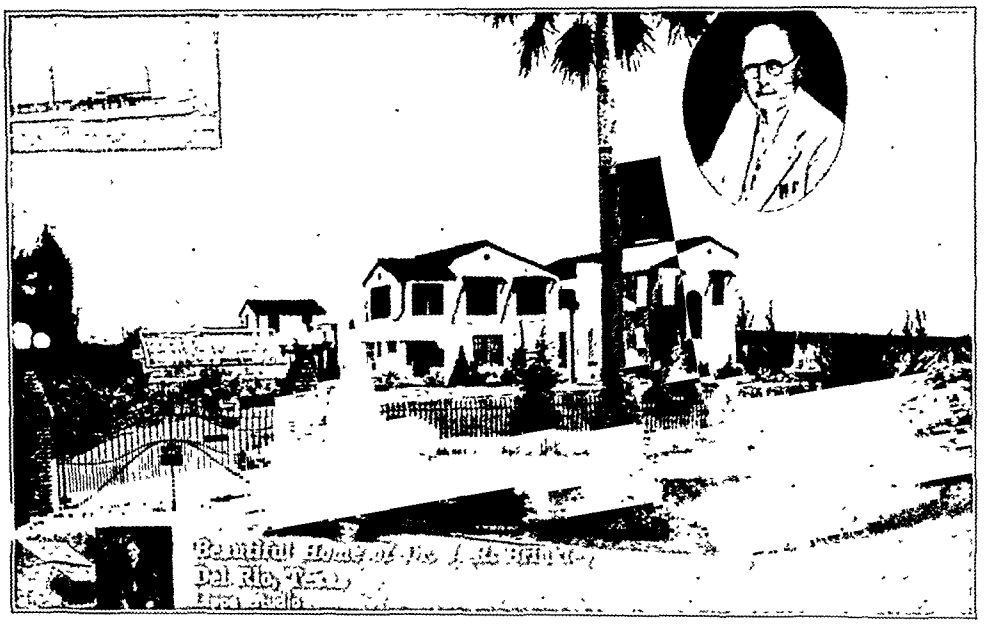
Q.—Then when you read thirty or forty a day, that means there are fifteen to twenty new patients a day? *A.*—Maybe it would mean that and maybe not; if that same patient comes in and gets his two routine plates and gives a history of sinusitis, or something of that kind, maybe I have to x-ray his sinuses or heart condition, or something of that kind.

Q.—Dr. Brinkley doesn't treat heart conditions, does he? *A.*—No, sir; but we want to know the condition of the patient before we start anything.

Q.—Is it you who diagnoses whether or not there is cancer of the prostate gland? *A.*—That is made by the examining physician, and the final is by the laboratory check, if we are able to check up on it in any way.

Q.—What part of it is it that you do there in that connection? *A.*—Well, if we have a bioscopy made I sometimes have to pass on that, but that is all I have to do with it.

Q.—Are you the main one that passes on the bioscopy? *A.*—Yes, sir.



Q.—Incidentally, tell the jury what a bioscopy is so it is clear? *A.*—Well, it is hardly a good practice, but it is done by old medical men, surgeons, at least; you have to get a piece of suspected cancerous tissue with as little traumatism and aggravation of the original mass as possible, put it into a freezing machine, freeze it and then slice it in two thin slices and place those under the microscope, after they have been stained, and make the diagnosis.

Q.—And you yourself are the one that finally says "this man has a cancer of the prostate" or "he doesn't have"? *A.*—I would under those conditions, but a man can make a diagnosis, often times—

Q.—I mean where the bioscopy is done? *A.*—Yes, sir.

Q.—What is done with the patients that you find do have the cancerous condition? *A.*—I don't know. They are advised to have cancer treatment.

Q.—Not at your hospital? *A.*—No, sir.

Reproduction of a postcard sold in Del Rio.

Q.—As a matter of fact, they are sent to another doctor there in Little Rock, aren't they, or do you know? *A.*—They might be advised to go there, but I don't know as any of them are ever sent there; a man is allowed to go to who he pleases on that deal.

Q.—Doctor, how long has it been since you were a member of the North American Radiological Association? *A.*—Oh, I guess it was about—I don't remember the exact years on that, but along about 1928 or 1929.

Q.—You weren't a member for several years before you went to Dr. Brinkley, is that right? *A.*—I was a member from, I think it was, around 1922 until I had financial straits that just tied me down until I couldn't keep up the bills, that is all.

Q.—How was it that you happened to go to Dr. Brinkley? *A.*—I was left stranded down at San Antonio with a wife and three kids, and I started in trying to make a living in South Texas, and there was next to nothing to start with, and I bucked the game over at the little town of Weslaco in the Winter Garden the best I could, and then I went to Karnes City, and from there to Poteet and finally into San Antonio, and in my messing around when I stopped at Karnes City for a spell I met a young fellow by the name of Alvis working in a drugstore there, and I got him out of a rut and got him started, and he happened to drive into Del Rio and start working for Jim Shearn over here in a drugstore, and Dr. Brinkley's x-ray man flew the coop for some unknown reason, I don't know why, and this boy knew my financial straits and he wanted me to come over and do x-ray work because he heard that I did that, and that is how I got there.

Q.—Since you were a member of the Twin City Urological Society, I assume you have done work in that field? *A.*—Only the x-ray side.

Q.—You don't know anything about the theory of the secretions of the glands? *A.*—Most every doctor gets some theory in his school life, but that is all.

Q.—What is your understanding in the function of the gland as to where the male sex hormones are produced?

THE COURT.—I don't think you should go into anything like that with this witness

Mr Reynolds —I will withdraw that.

Q —Who is your laboratory man? *A* —Garrett Kirschberg.

Q —Have you ever heard of anything such as a licensed laboratory technician? *A* —I have heard of a registered

Q —Not a licensed? *A* —That is right

Q —Registered? *A* —Registered with the International Society.

Q —A registered laboratory technician? *A* —Laboratory and urological technician, there are both, I don't remember the exact wording of the titles.

Q —Now, you are on a straight salary with Dr. Brinkley *A* —Yes, sir

Q —At the present time? *A* —Yes, sir.

Q —Doctor, in treating a person who has some residual urine, that urine is drawn off and that person feels many per cent better, doesn't he, a great deal better? *A* —Temporarily, until it fills up again

Q —And in the ordinary course of events it is quite a little time before it fills up again, that is, an average case? *A* —A few hours, perhaps

Q —Now, if you removed the residual urine for an elderly gentleman and gave him a week's rest in bed, why without doing anything more he is going to be in much better shape, isn't he? *A* —Possibly some better.

Q —And what I want to know, Doctor, is it your opinion as a medical man that tying off of the efferent ducts between the testes and the epididymis has any effect whatever on the size of the prostate gland? *A* —I don't know anything about that operation

Q —You have never heard of it in connection with the Brinkley Hospital? *A* —I have heard of it, but I couldn't swear that it is done, I didn't see it

Q —Do you have any reason to believe it is not done? *A* —No, sir.

THE COURT —That is speculation

RE-DIRECT EXAMINATION

By Mr. Morriss Sr.:

Q —Doctor, how long did you say it would take the bladder to fill up if you were to empty the bladder, where a patient couldn't do it? *A* —If you emptied the bladder and got it absolutely minus of anything, only the natural moisture on the inside there, and your kidneys were working it would be a few hours until he would have the same amount, and he wouldn't be able to pass but a little amount, and when he got his usual residue the overflow would pass

Q —That emptying doesn't have any immediate effect of curing a man? *A* —No, sir. He specified that you keep him in bed a week and keep it empty.

Q.—Then, that way, would that be of any permanent benefit, likely, or would that be temporary? *A* —Nature naturally repairs itself if you help it some, and he would be better off and be improved at the end of a week That is what he asked me

Q —That wouldn't have anything to do with the reducing of the prostate gland? *A* —I wouldn't think so

Witness excused

TESTIMONY OF L. C. CALDWELL

L. C. Caldwell testified that he operates the Val Verde Tourist Courts, that he is corporation judge of the city of Del Rio, and that the general reputation of Brinkley in the community is good He stated that many of the patients coming to the Brinkley Hospital had stopped at his tourist courts.

TESTIMONY OF J. TRAVELSTEAD

J. Travelstead testified that he is editor of the Del Rio *Evening News* and that the reputation of Brinkley is good. On cross examination, he stated that he is a close friend of Dr. Brinkley's and that he had given Brinkley liberal space, and that Brinkley had bought liberal space in his newspaper.

TESTIMONY OF DR J A MC DONALD

Dr. J. A. McDonald testified that he is a doctor of dental surgery, a member of various dental organizations, has lived in Del Rio twenty-one years and has known Brinkley since 1931 and that his reputation is good On cross examination, he stated that he is the dentist for the Brinkley family.

TESTIMONY OF W. PAINTER

W. Painter stated that he is a bus operator, living in Uvalde, Texas, and has been engaged in such a capacity for fifteen years, and that the reputation of Brinkley is good and that he is a peaceable, law-abiding citizen He also stated that he in his business has hauled patients in and out of Del Rio.

TESTIMONY OF JOHN DOBKINS

John Dobkins testified that he is in the automobile business in Del Rio and that the reputation of Brinkley is good On cross examination he testified that Brinkley was one of his customers.

The defense then offered in evidence a considerable number of exhibits in the form of pamphlets, circulars and other materials issued by Brinkley, and also the book entitled "Life of a Man," written by Clement Wood.

TESTIMONY OF J. H. MC COY

J. H. McCoy testified that he is investigator for the firm of Loesch, Scofield, Loesch & Burke of Chicago, and that in the course of his investigation he met a man named Crawford in the penitentiary in McAlester, Okla.; that he interviewed Crawford and was present when Mr. Burke took the deposition for the American Medical Association and Mr. Jackson for Brinkley, Mr. Jackson representing Dr. Brinkley. Mr. McCoy stated that he had not at any time made any promise to Mr. Crawford, that he had not paid him any money and that he has never seen Mr. Crawford since the time the deposition was taken.

DEPOSITION OF LESLIE DYE CONN

Mr. Harrell, representing the American Medical Association, read additional material from the deposition of Leslie Dye Conn, as follows:

DIRECT EXAMINATION

Questions by Mr. Harrell:

Q —Do all of those patients come to the country hospital rather than the city hospital? *A* —Yes, sir. They're supposed to, at least As far as I know, they do

Q —I mean by that they go out there for recheck? *A.*—Yes, sir.

Q —And is there any one else at the Country Club Hospital, besides yourself, who conducts those examinations? *A* —No, sir.

Q —Those recheck examinations? *A* —No, sir.

Q —Is there any operating done out at the Country Club Hospital? *A* —When they overflow up in town they do; once in a while

Q —Do they overflow up in town very often? *A* —Very often? Why, doggone, we can't take care of them

Q —Business is booming, huh? *A* —You ought to work a while and find out. Oh, we do take care of them, but then we are sure overflowed.

Q —Doctor, the patients who come to the Country Club Hospital for recheck, for what ailments have those patients received medical attention or surgical attention? *A* —For what ailments have they received—

Q —Yes? *A* —Those that I handle are for the prostate

Q —Those that you handle have all previously had operations for prostate? *A* —Yes, sir—or take. medical treatment for prostate

Q —Do you have many patients that take medical treatment for the prostate rather than surgical? *A* —Not many.

Q —Do you know what the medical treatment for the prostate is? *A* —Yes, sir.

Q.—As administered by Dr. Brinkley? *A* —Yes, sir.

Q —Would you tell us what it is? *A* —No, sir. It is not my privilege

Q —Well, why won't you tell us? *A* —Because it was given to me in confidence, and I am keeping it that way.

Q —Is it a secret treatment? *A* —Well, if he wants you to know it he'll tell you Now, that is all—

Q —But, at any rate, you refuse to divulge it, is that right? *A* —Yes, sir, that's right

Q —But you do know what it is? *A* —I do—at least, I know what he told us

Q —Did he also tell you not to divulge it to any one? I mean—by "he," I mean Dr. Brinkley. *A* —I can't tell you the conversation that took place—just don't remember it right now."

TESTIMONY OF DR. MORRIS FISHBEIN

Dr. Morris Fishbein was then called to the stand as a witness in his own behalf. He testified as follows:

DIRECT EXAMINATION

By Mr. Reynolds:

Q —Dr. Fishbein, now, for the purpose of the record, you are the defendant in this case, again, Dr. Fishbein? *A* —Yes, sir.

Q —Doctor, have you ever authorized the expenditure of any funds, either your own or those of the American Medical Association, for the purpose of paying it to, giving it to or delivering it to a prospective witness in any legal proceeding? *A* —Absolutely not.

Mr Morriss Sr —We object to that as incompetent, irrelevant and immaterial to any purpose in this case.

THE COURT —Overrule the objection

Mr. Morriss Sr.—Note our exception.

A —Absolutely not.

Q.—Dr. Fishbein, prior to the time you came down here on this lawsuit had you ever heard of the deposition of James E. Crawford? *A.*—I had never heard of Mr. Crawford's deposition prior to the time I came to attend this suit.

Q.—Now, Dr. Fishbein, is there any recognized and recorded medical evidence that the goat gland implanted in the testes has the same effect of the administration of male sex hormones?

Mr. Morriss Sr.:—We object to that for the reason that it is not a matter that is proper at this time; the plaintiff had put on his case and the defendant put on its rebuttal and went into all of those matters at the time and put on their testimony, and the plaintiff has put on the rebuttal, and it is not proper now, of course, to seek the advantage of putting on this kind of testimony.

THE COURT:—I think it is proper to rebut Dr. Brinkley's testimony.

Mr. Morriss Sr.:—His testimony was in rebuttal, it was their rebuttal testimony, and if we are going to rebut back and forth—

THE COURT:—You can have sur-rebuttal, can't you?

Mr. Morriss Sr.:—I don't think it is proper.

THE COURT:—As I remember, when you had Dr. Brinkley on the stand he was asked about that and he said he was inclined to think that that was the effect of the insertion of those goat glands but that he may in his own enthusiasm, I believe he expressed it, have been mistaken.

Mr. Morriss Sr.:—This witness and other witnesses expressed their ideas about it.

THE COURT:—You can't close up their case, and they have a right to rebut your case if they want to.

Mr. Morriss Sr.:—We think it is not a proper practice after they had their case, a proper practice to undertake to go back on the stand after the plaintiff had closed the case in rebuttal.

THE COURT:—Dr. Fishbein has been on the stand once, and this makes the second time, and Dr. Brinkley was on twice.

The Witness:—Twice.

Mr. Morriss Sr.:—We don't think it is a legal criterion, and we object to it because it is a matter that has been gone over and because it is not proper in any sur-rebuttal.

THE COURT:—Nobody is quicker than the Court to stop the testimony when they try to indulge in repetition, and you know that, and I have been doing it all week, but I think they have a right to ask the question, and I will overrule the objection.

Mr. Morriss Sr.:—We make the further objection to this testimony that it is incompetent, irrelevant and immaterial to any issue in this case, and it is collateral. If it were for the purpose of contradicting anybody—it is wholly a side issue and it is incompetent to establish any issue in this case.

THE COURT:—My understanding is, and I presume they do introduce it for the purpose of contradicting Dr. Brinkley's testimony, and if it wasn't for that purpose I woudn't admit it.

Mr. Morriss Sr.:—It is on a collateral matter, and, further, it is hearsay

THE COURT:—Go ahead.

Q.—Is there any accepted, recordable evidence, recorded evidence that the goat gland implanted in the testes has the same effect as the administration of the male sex hormone?

Mr. Morriss Sr.:—That calls for a conclusion "is there any recorded acceptable evidence," and it would call for the speculation and conclusion, and that is certainly improper, in addition to the other reasons.

Q.—To your knowledge?

THE COURT:—Overruled.

A.—I do not know of any article published anywhere in all of the medical literature that I have seen that shows there is the slightest resemblance between the action of the implanted goat gland and the administration of the male sex hormone.

Q.—Is there any evidence that any of the Steinach operations, either 1 or 2, as defined here, produces the same effect as the giving of the male sex hormone?

Mr. Morriss Sr.:—The same objection, may it please the Court, to all of that, and for the reason that it is not the best evidence.

THE COURT:—I don't know about that.

Mr. Reynolds:—I will confine it as to if he knows.

THE COURT:—I don't know whether the witness is qualified to testify as to what the Steinach operations are.

Q.—Dr. Fishbein, have you made any study of the literature on the production and the effect and the manufacture and the administration of sex hormones and sex hormone preparations? *A.*—I have.

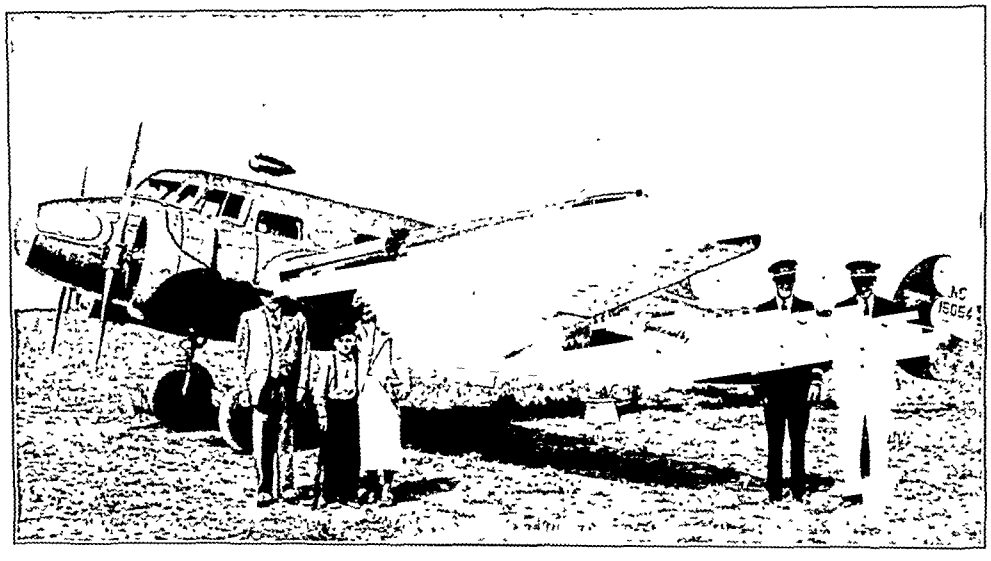
Q.—Will you state what? *A.*—I am a member of the Council on Pharmacy and Chemistry, which regularly examines the constituents and studies claims of all gland products used in the practice of medicine, and it regularly publishes its report concerning the status of such glandular preparations in the practice of medicine; I have also made a study of the Steinach operations and have published a report on the various operations used for the purposes of rejuvenation.

Q.—All right, now, Doctor, I will ask you if in connection with your work you have found any acceptable evidence that any of the Steinach operations produce the same effect as giving the male sex hormone?

Mr. Morriss Sr.:—May it please the Court, to ask whether he has found, in the first place, calls for his opinion and conclusion about which he is not qualified to give, and in the second place, what he has found to be the best evidence, and, in the third place, he wants to know if it is acceptable to him and he is going to be the criterion; further, it calls for a conclusion and is incompetent.

THE COURT:—I think, possibly, your question is framed improperly, counsel, and I will sustain the objection to it in the form that it is in.

Q.—Dr. Fishbein, has there been any literature in connection with your work of that kind that has come to your attention advancing the theory that either of the Steinach operations produce the same effect as giving the male sex hormone?



Mr. Morriss Sr.:—The literature would be the best evidence, and there is no accounting for the absence of the best evidence; that objection, in addition to all of the others.

THE COURT:—Overruled.

Mr. Morriss Sr.:—Note our exception.

A.—The published reports of the Council on Pharmacy and Chemistry and the published reports of the investigators who have from time to time performed operations similar to the Steinach operation are preponderantly—

Mr. Morriss Jr.:—The answer shows itself to be hearsay and to come through several different—

The Brinkley airplane, the family and the pilots.

THE COURT:—I don't think you listened to it, Doctor. The question wouldn't require the character of answer you are making.

Mr. Morriss Jr.:—We move that the answer be stricken and that the jury be instructed not to consider it.

THE COURT:—Yes, sir. The answer, so far as it has gone, will be stricken.

A.—No.

Q.—Have there been reports of investigation, so far as you know, directly to the contrary?

Mr. Morriss Sr.:—The same objection, may it please the Court, and the reports we think would be the best evidence, and it would be hearsay and a conclusion, and for all the reasons we have objected to it.

THE COURT:—What is your question?

Mr. Reynolds:—If for no other purpose—I think there are several others—but if for no other we pursued this line of testimony on the ground of the Doctor's good faith in making the statements about the plaintiff in this case.

THE COURT:—I know, but I don't think the Doctor or the plaintiff either one had any idea about the Steinach operation when they started out on this business. That is a matter that has come up here in your examination of Brinkley when you asked about those various doctors and he started talking about Dr. Steinach and other doctors elsewhere, and I think the form of your question now is improper in regard to that. I think that this witness having qualified as an expert you could ask him generally if he knows as a medical man whether the Steinach operation is commonly accepted by the physicians, and let him answer yes or no and explain it if he wants to and then get through with it in that way.

Mr. Reynolds:—Your honor has put the question better than I could.

Q.—Doctor, will you answer the question as put by the Judge? *A.*—I have written a report on various rejuvenation operations, of which the Steinach is one type. To explain myself, in that report I make the statement—

Mr. Morriss Sr.:—Just a minute.

THE COURT:—I wouldn't go into the report, just state what you know now.

A.—As a result of my studies of the results of the Steinach operation I find it doesn't have the effects of the administration of the male sex hormones.

Q.—What is the scientific name for the product generally used as the male sex hormone? *A.*—Testosterone propionate.

Q.—Is this made out of testicular properties or not?

Mr. Morriss Sr.:—We object to that.

THE COURT:—Overruled.

Mr. Morriss Sr.:—Note our exception.

A.—It is not.

Q.—Is it derived in anyway from goat gland tissue? *A.*—It is not.

Witness excused.

At this point the defense rested its case.

March 28

The plaintiff moved that the Court direct a verdict for John R. Brinkley, and the Court discussed with the attorneys the question of the nature of the charge to be given to the jury by the Court; next came the addresses to the jury by the representatives of the plaintiff and the defendant, after which the judge made to the jury the following charge:

IN THE DISTRICT COURT OF THE UNITED STATES FOR THE WESTERN DISTRICT OF TEXAS DEL RIO DIVISION

J. R. BRINKLEY
vs.
MORRIS FISHBEIN
} No. 202-Law.

CHARGE OF THE COURT

R. J. MCMILLAN, Judge. Delivered March 29, 1939.

Now, gentlemen, I am going to give you the charge of the Court, and while in charging you it is going to be necessary for me to read from various books and papers which I have here on the bench, still the Court's charge will be oral and you will have no written charge to take into retirement with you. Accordingly, I ask you to give me good attention in order that you may remember the Court's charge as well as possible when you come to discuss the law and the facts in the privacy of the jury room.

At the outset, I want to give you some conception as to the function of a federal judge in charging the jury. Many of you may have served in cases on the state court dockets where the practice is very different from what it is here. There the judges are not allowed to comment upon the weight of the evidence or express any opinion with regard to it. Here, if the Court comments fairly and makes it clear to the jury that they are the triers of the facts, he is not only allowed to discuss the evidence with the jury but it is his duty to do so.

The Supreme Court of the United States in a famous case decided not so long ago said this about the matter:

"In a trial by jury in a federal court, the judge is not a mere moderator, but is the governor of the trial for the purpose of assuring its proper conduct and of determining questions of law. In charging the jury, the trial judge is not limited to instructions of an abstract sort. It is within his province, whenever he thinks it necessary, to assist the jury in arriving at a just conclusion by explaining and commenting upon the evidence, by drawing their attention to the parts of it which he thinks important; and he may express his opinion upon the facts, provided he makes it clear to the jury that all matters of fact are submitted to their determination. Sir Matthew Hale thus described the function of the trial judge at common law: 'Herein he is able, in matters of law emerging upon the evidence, to direct them; and also, in matters of fact to give them a great light and assistance by his weighing the evidence before them, and observing where the question and knot of the business lies, and by showing them his opinion even in matters of fact; which is a great advantage and light to laymen.' Under the Federal Constitution the essential prerogatives of the trial judge as they were secured by the rules of the common law are maintained in the federal courts.

"This privilege of the judge to comment on the facts has its inherent limitations. His discretion is not arbitrary and uncontrolled, but judicial, to be exercised in conformity with the standards governing the judicial office. In commenting upon testimony he may not assume the role of a witness. He may analyze and dissect the evidence, but he may not either distort it or add to it."

So you see the province of the Court here is not only to instruct you with regard to the law, but to assist you as far as he properly can with regard to the facts in the case. I make that statement to you for the reason that one of the counsel yesterday in arguing to you seemed to be under the impression that the Court had no function here except abstractedly to tell you what the law is. Such is not the case.

In this case the plaintiff sues the defendant for damages which he claims to have sustained by reason of the publication in a periodical of an allegedly libelous article, and he states not only that he has sustained actual damage by reason of humiliation, and injury to his reputation, both as a man and in his profession, but that he is entitled to what we call exemplary or punitive damages.

He alleges that this article was published in the February 1938 issue of the magazine *Hygeia*. While I dislike to take the time, yet in view of the instructions I am going to give in connection with the matter it is necessary for me to sketch with you briefly the part of the article charged on.

It is charged, substantially, under the heading of Modern Medical Charlatans that "in John R. Brinkley quackery reaches its apotheosis"; "He continues to demonstrate his astuteness in shaking shekels from the pockets of credulous Americans, notwithstanding the efforts of various governmental departments and agencies." It goes on to assert that upon the removal of his radio station he departed for Mexico and he is now broadcasting at Villa Acuna; that all sorts of efforts have been made, without success, to remove him from the air; that he reads the symptoms of patients and then by remote control prescribes the pill that they should use. You send him your dollar and you get your pill; that he has performed peculiar operations at the hospital, one of the main ones of which is the compound prostate operation for elderly gentlemen; that he has a high pressure man in his front office who makes sure that those who come to the hospital will have the money to pay in advance for the work and so forth. Most of the business seems to come through the mail, and it is time for the Post Office Department to do something with regard to the use of the United States mail by Dr. Brinkley in defrauding the public. Then it states the amount that he is supposed to have made out of his various quackeries; that he is the possessor of certain yachts, and travels abroad, and then it makes the allegation with regard to the fact that they do not mix and mingle with the passengers on the boats.

It is unnecessary for me to read the article to you verbatim because it has been read to you several times, and in sketching it to you I have said enough to recall to you the contents of the part which is declared on in plantiff's pleading. Those parts which are declared on do not constitute the entire article, but they are the only parts which the plaintiff alleges damaged him. And, accordingly, while you may consider the entire article as I shall say to you later for other purposes, you will only consider the elements of damages, if any, that may have flowed from that part of the article charged on in the pleading.

To this complaint the defendant responds by substantially two defenses. In the first place he says that the article is true; in the second he says that should the article chance in any particular to be in error or false, it relates to a matter of public concern and one with regard to which he was under the duty to write, and that it constitutes under all the facts and circumstances of the case a fair comment and criticism, and such being true it falls under the privilege accorded to articles of that kind by the statute.

So the issues are made up in that way, and they become comparatively simple, though the statment of the law with regard to them is not so simple.

The Texas statute with regard to libel provides in part and substantially in article 5430 of the Annotated Code that a libel is a defamation expressed in printing or writing tending to blacken the memory of the dead, or tending to injure the reputation of one who is alive, and thereby expose him to public hatred, contempt or ridicule, or financial injury, or to impeach the honesty, integrity, or virtue, or reputation of any one, and thereby expose such person to public hatred, ridicule, or financial injury.

Under this definition of libel it is of course obvious that this article falls under the heading of one which would be known as libelous per se, that is to say, that if the statments were made in that article they would upon their face be libelous and defamatory unless they were in some other way explained or justified.

Now, article 5431 of this same title of the Texas Statutes says that in any action for libel, in determining the extent and source of actual damage and in mitigation of exemplary or punitive damage, the defendant may give in evidence, if specially pleaded, all material facts and circumstances surrounding such claim of damage and the defense thereto, and also all facts and circumstances under which the libelous publication was made, and may also give in evidence, if specially pleaded in mitigation of exemplary or punitive damage, the intention with which the libelous publication was made. Then follows a statement of law to which I call your attention.: The truth of the statement, or statements, in such publication shall be a defense to such action.

The statute then goes on further to deal with the matter, and in article 5432 it treats of privileged matters. By privileged matters we mean things that are written or said upon occasions which are privileged. That is to say, upon an occasion for which the party cannot be held to account. To illustrate the matter for you I might give you a few examples: For instance, a congressman speaking in the halls of Congress at Washington cannot be held to account for what he says there. It is considered good public policy to allow him to talk without restraint, and he has the privilege. The occasion is privileged and he is not liable in damages for it. The same thing is true with regard to members of your legislature. To bring the matter more closely home to you, the same thing is true with regard to proceedings here in court. The judge of the court could not be held liable elsewhere for any remarks made in the trial of a case in court, nor could the attorneys be held liable for pleadings filed or remarks made in argument, nor could any member of the jury be held liable for anything that he might say in the jury room in the discussion of the case.

So far as the libel laws are concerned, that, gentlemen, is what we mean by privileged. The occasion is under certain circumstances supposed to be privileged, and the general effect of it is this, as I have just said to you, the proof of the truth of an article is a defense, whether the article is privileged or not, but if the article be one which is privileged then there is no liability whether it is true or not. The question of malice or lack of malice does not enter into it.

Accordingly, the Texas statute, which has recently been amended, says substantially and in part as follows: The publication of the following matters by any newspaper or periodical shall be deemed privileged and shall not be made the basis of any action of libel. Then after setting out several matters with which we are not concerned it says this: A fair and reasonable comment or criticism of matters of public concern, published for general information. So you will have observed that the truth of the article published constitutes a complete defense, or even though the article should not be true, if it constitutes a publication in a newspaper or periodical of a matter relating to something of public concern and published for general information and is a fair and reasonable comment or criticism with regard thereto, then it is privileged and the party publishing the article or writing it for publication cannot be held liable in damages for it.

The plaintiff in this case has chosen to base his suit on individual sentences and groups of sentences selected from different portions of the magazine article. In your consideration of the defense of truth made by defendant you should consider the publication as a whole insofar as the remaining portions of the magazine article cast light upon the meaning of the specific portions of the article made the basis of the plaintiff's suit. The sting of the language complained of, that is, the statement of the portion of the article which is the subject of this suit, is, in my opinion, the charge that the plaintiff is a quack and a charlatan, and the further charge that he is using the mails to defraud.

The words quack and charlatan have substantially the same meaning. Many definitions can be found in the dictionaries or in the reports of the courts. A common definition of the word quack is to make vain and loud pretensions, especially of medical ability; to boast, to vaunt aloud or be a boastful pretender to medical skill or to make extravagant claims for a cure-all; to advertise with fraudulent boasts. You are not limited, of course, to these definitions that may be found in a dictionary. In considering the matter, the words used in the article are to be construed in the way they would be construed and understood by the ordinary reader of the magazine, keeping in mind the general class of people who would read a magazine of the kind in which this article was published, and if you find that the sting or substance of the specific portions of the article complained of is substantially true, then you will return a verdict for the defendant.

As I have said to you, the defendant takes two grounds of defense. In the first place, that that which he has published is true, and in the second place the entire article and the portions of which the plaintiff complains of was written as and constitutes a fair and reasonable comment and criticism of matters of public concern, published for general information.

You will find that certain portions of the published matter of which plaintiff complains is substantially true; in fact, certain portions he has testified to on the stand and has admitted their truth, at least in substance. Now, if you find those portions which have not been admitted true, or which you do not find to be substantially true from the evidence, constitute a reasonable and fair comment or criticism with regard to matters of public concern when viewed in the light of the statements in the article which you find to be substantially true, your verdict should be for the defendant, even though you find such other matters of comment and criticism to be false.

In this connection I instruct you that in order to establish the defense of truth of the article it is not necessary for the defendant to show literatim and verbatim that every word in the article is literally true. If the substance of it be true, that is to say, if the part of it which is injurious be true, if it be substantially correct, then the defendant has made out a defense, despite the fact that there may be certain particulars in which the article would be in error. In other words, it is the sting of the article, the general purport of it, that is to be considered. For instance, to give you a homely illustration of the matter, suppose I should say that you had backed your truck up to my pasture and cut my fence and stolen twenty-seven sheep from me and carried them off. If on being sued in the matter I could only prove that you had stolen eighteen, what I had said wasn't literally true because I said you had stolen twenty-seven, while as a matter of fact you had only taken eighteen. But the libelous feature of the statement doesn't consist in the exact number of the sheep, it consists in the allegation of the theft of the sheep. If it was proved that eighteen were taken, that would constitute a defense to the action, despite the statement made was that twenty-seven were taken. In other words, if the substance of the article is established as substantially true, then should it be true that there are one or two misstatements which do not change the general tenor of the article, that doesn't affect the defense of truth, in the light of the law.

Now, the defendant contends that the matters dealt with in the article complained of were matters of public interest and of public concern, published for general information. It is

obvious, of course, that matters of public health are matters of public concern. We see that evidenced every day by the laws of the country, by the conversations of the people, by the articles which appear in magazines and newspapers. It is evidenced by the fact that the state has and exercises the power to license those parties who practice medicine, and it is an offense in most jurisdictions to practice medicine without a license. We constantly see people prosecuted for that. The state has and exercises the power to license pharmacists, people who compound prescriptions and dispense them to be used in the treatment of the sick. The same is true, collaterally, with regard to the practice of law. It is a matter that affects the public interest, and the state has prescribed certain standards for it and it is an offense to practice law without a license.

Accordingly, it occurs to me that as a matter of fact, and in discussing the facts with you, anything in a general way which affects the public health is a matter of public concern.

Now, it might be reasonably argued and might be true that an individual doctor who was pursuing his practice in the ordinary way in some town wouldn't be such a matter of public concern that any one would be justified in writing an article about him, but if a doctor extends his practice to cover the country, advertises his ability not only in writing but over the radio and attracts to the place where he practices his profession an unusually large number of people, that is to say, a number entirely disproportionate as far as one doctor would be ordinarily concerned, then his activities do become a matter of public concern, and should it happen that his practice is of such a character that the public health is affected one way or another thereby the parties would be entitled to write about it, and if the comments constituted a fair and impartial criticism there would be no liability. On the other hand, of course, the individual citizen has his rights. Among those rights is the one which entitles him to be protected against libel or slander, and if the comment or criticism is not impartial or is not fair, then despite the fact that it may be a matter of public concern there would be liability for it.

The defendant further contends that the plaintiff by his advertisements invited the people to submit to his system of treatment, and that if he, the defendant, really believed it to be of little or no value then he had the right to maintain that it was so and that even if in drawing inferences of bad intention he fell into error, yet if he wrote honestly and with the intention of exercising his vocation as a public writer fairly and with reasonable moderation, he is entitled to a verdict. Here is a man bringing forward what he professes to be new systems of treatment and inviting the public to consult and patronize him as the only effective means to cure certain ailments. In doing this he challenges public criticism, and if a public writer, using a reasonable degree of temper and moderation, as behooves any one that makes imputations upon others, thus discussing the subject in the exercise of his vocation, falls into error as to the facts or the inferences and goes beyond the limits of strict truth, he is nevertheless privileged. The occasion is a privileged one, and if the privilege is exercised honestly, faithfully and with reasonable regard to what truth and justice require, and if the comment or criticism is fair and reasonable, then though he may exceed the limits of what he can legally prove to be the truth he is protected from liability.

In connection with your consideration of the defense put forward by the defendant that the portions of the article complained of and taken together with the remainder of the article constitute reasonable and fair comment and criticism of matters of public concern, published for general information, you may consider the question as to whether or not the plaintiff's conduct is unprofessional in its nature. In determining what is professional and not professional conduct of the physician you may take into consideration the rules of ethics followed by the great majority of medical men and which are recognized generally in their profession. Most people know in a general way what you mean by ethics, but few of us think or speak in terms of definitions, and it is well sometimes to refresh our memory or knowledge by looking to definitions. Webster's Dictionary says with regard to ethics that it is "the science which treats of the nature and laws of the actions of intelligent beings, these actions being considered in relation to their moral qualities; the science which treats of the nature and grounds of moral obligation; the science of human duty" and secondly, "a particular system of principles and rules concerning the duty, whether true or false; rules of practice in respect to a single class of human actions; as social ethics; newspaper ethics," and so forth. And in speaking with regard to the word ethical he says it is "relating to morals; treating of morality; containing precepts of morality," and so forth. The term as applied to the liberal professions such as the practice of medicine or the practice of law is generally understood to mean that course of conduct pursued by recognized moral practitioners either of medicine or of law.

It doesn't necessarily follow that every slight deviation or change by a doctor or a lawyer from what the general body of the doctors or lawyers do would be unethical, but if his course of conduct was far beyond and contrary to the course of conduct which the other members of his profession followed, then you would say that he was unethical either in the practice of medicine or in the practice of law.

As the evidence here shows, it has practically always been considered unethical for physicians to advertise, that is to say, to advertise further than to call the attention of the public to the fact that they were there ready to practice, and by some character of card giving their location or address, or if they specialize in some particular kind of practice to so advise the public. Advertisements by which prizes are offered to secure patronage or by which claims are made of superior skill or ability are not ethical, and you may consider those matters in this case in passing on the question as to the truth or falsity of the charge. In other words, it is one of the component elements that go to make up the question as to whether this man would be classified as a quack or not. It is not entirely determinative, but it may be that it is entitled to consideration. Accordingly, in determining what is professional and unprofessional conduct by a physician you are entitled to take into consideration the rules of ethics followed by the great majority of the medical men and which are generally recognized in their profession. The conduct of the plaintiff Brinkley should not be measured against his own personal ideas with regard to what is proper. It should be measured against the ethics and approved conduct of physicians generally, and to such extent that his conduct as a physician varies from the rules of ethics recognized and observed generally he becomes subject to criticism, and criticism of his conduct is privileged unless unduly excessive and the terms of the criticism are unreasonable or unfair.

The defendant, as I have said, put forward as a defense to this article the contention that the article complained of is a fair comment and criticism of matters of public concern, published for general information. The defendant wrote the article in question as editor of a magazine of national circulation, published by a voluntary organization to which a large number of licensed physicians in the United States belong. You therefore have to consider the question as to whether or not the portions of the article complained of by the plaintiff, when taken in their context and in connection with the remainder of the magazine article, constitute a reasonable and fair comment and criticism of the plaintiff and his medical practices. In determining this matter you should bear in mind that if you find it is true that the plaintiff is taking large sums of money from the public through pretending to have medical skill and that he does not have such skill and is thus preying upon the ignorance of a large number of people, the defendant would be justified in using strong language in denouncing the plaintiff, and you should bear in mind that ridicule is often the strongest weapon in the hands of a public writer, and if it is used in a way to emphasize matters with respect to which strong and definite language would, in the very nature of the occasion, be used, then it does not in any way render the comment or criticism unreasonable or unfair.

In other words, if you should find that the nature of the matters to be discussed is such as to warrant criticism or condemnation, then the defendant is not required in writing to write a mere colorless article, stating simply and only matters of fact as a newspaper reporter might in describing a fight or fire or something of that variety. He is entitled to put in his article, if it is reasonably and properly done, what you would call punch. As the courts have held with regard to matters of this kind, ridicule or sarcasm are frequently effective, and if they are justified by the facts then there is no liability for their use.

Of course, you are the triers here of the facts, and it is for you to determine whether upon the facts as you have heard them here this article constitutes a fair and reasonable comment or criticism of Dr. Brinkley and his activities. If you are of the opinion that his activities are of such a character as to render them a matter of public concern and that his conduct is unethical and that his claims are unwarranted then you are entitled to consider the question as to whether the defendant in writing this article has expressed his comment and opinion in such terms as fairly to carry those facts home to the public generally. There is no use blinking the fact that this article was intended to have a wide circulation. It was intended to carry the defendant's viewpoint of Dr. Brinkley's operations to everybody that he could get it to. If his viewpoint is correct, then his purpose and his action are highly laudable. On the other hand, if his viewpoint was incorrect and he proceeded upon a false premise, then his purpose and object was not laudable and he is liable in damages.

The burden is upon the defendant, Dr. Morris Fishbein, to prove his defense, namely, the substantial truth of the charges sued on and the claim of privilege that the article sued on was not more than a fair and reasonable comment on a matter of public concern, by a preponderance of the evidence.

You are instructed that if you believe and find from the evidence that the statements of fact contained in the portion of the article sued on are not true, and if you further find and believe from the evidence that such statements were not justified as privileged communications as defined to you in the Court's charge, then in such event you must find and return a verdict for the plaintiff and you must assess such damages as you may find under the Court's charge as herein given you either actual or actual and exemplary. In this connection you are charged that damages are presumed by the law to flow from any libelous statement concerning another. And if it is libelous and not justified plaintiff is entitled to recover such actual damages as would ordinarily flow from or be occasioned by such libelous statement, including damages for humiliation, mental anguish and suffering and injury to his feelings and for injury to his reputation, both personally and professionally, whether there is proof of damages in such respects or not.

We have in law what are known as exemplary or punitive damages. They are damages which are not intended to cover any actual or special damages that have been sustained. They are not intended to put you back in the place that you were before you were injured but are intended by way of exemplification or punishment or by way of reprisal. They operate in effect as a sort of private fine, and those damages are only allowed in libel cases where actual damages are found to have been sustained and further where actual malice is shown to have existed. By malice we mean ill will, bad or evil motive or such gross indifference to the rights of others as will amount to wilful or wanton conduct. Malice cannot be inferred merely from the fact of the publication. As said in Texas Jurisprudence, "While the existence of actual or express malice is not presumed as a matter of law, and must be proved, it need not be proved by direct or extrinsic evidence; evidence of facts and circumstances from which it is reasonably inferable is sufficient to show its existence. It may be inferred from the relation of the parties, the circumstances attending the publication, the language used, and from the words or acts of the defendant before, at or after the time of the communication; but there must be evidence from which the jury can infer malice existing at the time of publication and actuating it. Malice is not implied or presumed from the mere fact of the publication, nor may it be inferred alone from the character or vehemence of the language used, nor found from the falsity of the statement alone."

Now, it is not possible to give you any exact yardstick by which you can measure damages, in a case of this kind, should you find the plaintiff is entitled to recover. The law allows recovery for certain damages of an intangible sort which you cannot press down into a corner and determine like you can certain other damages. If you should kill your horse you could prove the damages exactly by proving the market value of the horse, but if I should hurt your feelings nobody knows exactly what damages have been occasioned you by having your feelings hurt. Accordingly, when you come to consider the question of the damages that somebody suffers by reason of humiliation or by reason of injury to his reputation, either personally or professionally, that is a matter which has to be left to the good judgment and discretion of the jury. Of course, in dealing with injuries to professional reputation, if special damages were alleged and proved, that is, you showed that a man actually lost something specifically, it could be recovered, but there is no such proof here in this case.

When it comes to the question of the measure of damages that would be applied should you conclude to allow punitive or exemplary damages, that again is a matter which is not susceptible of ascertainment by any rule of thumb. They have to be damages in such an amount as you would consider a sufficient punishment for doing a wanton or malicious thing, and of such a character as to deter other people from doing the same thing.

In passing upon this question of damages, should you come to the matter of damages, should you conclude that there is any liability here upon the defendant, then you are entitled to take a great many things, as I view it, into consideration. This plaintiff here claims humiliation by reason of the publication of an article which accuses him of being a quack, and which states that he is getting large quantities of business through the mails and probably should be investigated for violation of the mail fraud statutes. In other words, he says that he has been humiliated, his feelings have been hurt, that he has been shamed and that he has been injured both in his reputation with his neighbors and in his reputation as a doctor. Accordingly, when he says that, he puts in issue not only his reputation, his feelings as they exist now, but he puts in issue practically the entire course of his professional life.

Now, I am discussing this matter with you not from the law standpoint but from the standpoint of the facts, which, as I read to you in the decision from the Supreme Court of the United States, it is my duty to do.

There is no doubting the fact that this plaintiff has been the subject matter of a great deal of trouble and controversy and difficulty in many places in this country and abroad. The question as to his ethics as a physician and his right to practice medicine has been up not only once or twice but several times. He has been tried in Kansas on the issue as to whether his conduct was of such a character that his right to practice there should be canceled, and the evidence shows it was canceled. There was a general cancellation of licenses in Connecticut, and his and a number of other eclectic doctors' licenses were canceled. There has been some character of cancellation or some character of proceedings against him in the state of California. His right to continue to broadcast over the station which he had in Kansas has been investigated and discontinued by the United States government. Some character of a degree that was conferred upon him or a certificate of some character, I am not clear exactly what it was, by some university in Italy has been canceled. It is manifest from his own evidence and the evidence here that this is not the first time that articles of this kind have been written about him. In fact, it is testified here that a suit between him and this same party, Dr. Fishbein, was maintained in Kansas some few years ago and depositions from that suit have been offered here in evidence. According to his own testimony he has been convicted of a violation of the law with regard to the sale of alcoholic spirits and was assessed a fine and some jail sentence, which jail sentence I believe he states he did not serve.

He has published a book, or rather he got some man, according to his evidence, to write a book about him called "The Life of a Man," and according to his evidence he has circulated this book and is circulating it. I don't believe he says he ever sold it, but it has been in general circulation and he says that he has given many copies of it away. Now, in this very book which he has written about himself and which he is circulating he quotes from the opinion of the Supreme Court of Kansas in sustaining the action of the board in canceling his license to practice medicine, in which it there says "The Supreme Court was hardly impartial in its denial of Brinkley's claim, since it went beyond the charges in purporting to express them; holding that they held that Brinkley was 'an empiric without moral sense, and having acted according to the ethical standards of an impostor, the licensee has performed an organized charlatanism until he is capable of preying on human weakness, ignorance and credulity to an extent quite beyond the invention of the human mountebank' . . . who was 'fleecing the defective, the ailing, the gullible and the chronic medicine takers who are moved by suggestion, and is scandalizing the medical profession and exposing it to contempt and ridicule.'"

This part of the book was offered here in evidence, and of course you are entitled to consider it.

Now, I do not comment upon that in order to applaud any court for writing anything of that kind. Nor is it called to your attention as tending to substantiate in any way any fact that is stated therein, but the thing that occurs to me about it is that if a man feels he is capable of humiliation by virtue of an article of the character sued on here, then why would he in a book of his own copy a thing like that said about him and give it currency? In other words, you have to consider, as one of the old English law lords said, the question as to what reputation a man has in passing upon the question as to the amount of damages that are sustained.

In Jones on the Law of Evidence this quotation occurs, "Lord Ellenborough long since tersely stated the doctrine which still prevails: 'Certainly a person of disparaged fame is not entitled to the same measure of damages with one whose character is unblemished, and it is competent to show that by the evidence.'"

Now, those are matters which are entitled to consideration in passing upon the question as to whether this article, if libelous, has occasioned damages. You can very readily see that if you take a person of a very retiring, shrinking, modest disposition and make some false, scandalous and ugly charge against him you might humiliate and hurt him terribly. On the other hand, if you take somebody who has been on the firing line all his life and had that kind of thing said about him time and time again, the saying of it another time might not hurt him any more than water rolling off a duck's back. It is frequent that men in public life who are constantly abused and libeled, because of their position, have become so accustomed to it that any humiliation or shame with regard to such matters has long since ceased to exist. It doesn't mean that if the article is libelous and untrue it is justified, but I am discussing it with you now purely and simply from the standpoint of the extent of the injury, if any. You are entitled to consider the background of the doctor. He has apparently made no secret of his background. In passing upon the question as to whether his reputation has been injured with other people you are entitled to consider the question as to whether these same things or things of this same character have been said before and general circulation given to them. It doesn't mean the party who says them again would not be liable for damages if they were libelous, but it does mean that you are entitled to consider those questions in passing upon the extent of the damages.

In cases in which articles are found to be libelous, but no actual damages result, nominal damages follow as a matter of law. Upon nominal damages punitory damages may be cumulated if, as I have told you before, it is found that the article is libelous and that malice, as I have defined that term to you, existed in connection with it.

Now, the defendant says another thing here which he is entitled to have called to your attention, and that is he believed these things he said in this article were true. To support that contention the Court allowed evidence here with regard to certain sources or avenues of information which he consulted or examined. Those things were not allowed to come in as tending to prove the truth of the facts set out either in those articles or in those reports but were allowed to come in evidence, as I told you at the time, for the purpose of determining the question of the defendant's good faith. That is to say, the law says that if I libel you by publishing something that is false, then I am liable to you for damages, but if at the time I published it I did it in good faith and I believed it to be true and I had reasonable grounds upon which to base my belief of the truth of the charge, then the jury can consider those facts by way of mitigation of damages, that is to say, by way of reduction of damages; and that I charge you is the law with regard to that phase of the matter.

Does that sufficiently cover your requested charge on that phase of it?

Mr. Morriss Jr.:—Yes, sir.

THE COURT:—You are, of course, the exclusive judges of the credibility of the witnesses, of the weight to be given to their testimony and of the facts proven. The law in the case you must receive in this charge from the Court and be governed thereby.

Insofar as I have discussed the evidence with you or made any comments with regard to it or expressed any opinions with regard to it, I did so for your assistance, and if my comments or expressions or opinions are in harmony with your views then you may accept them, otherwise you may reject them, for as to the facts you are the triers thereof, bound only by your conscience and by your oaths as jurors.

This case has been tried at some length and it has been thoroughly and conscientiously developed and argued by counsel for both sides, and it would be idle to say it isn't a case of some public interest because we all know it is. Whenever a man assumes the prominence that the plaintiff in the case has and a man has the prominence of the defendant in the case and they meet upon the legal battleground, naturally it attracts the attention of the public. There are many people who are interested one way or the other in the outcome of it. I don't think there is any monopoly of opinion on either side, but what I want to convey to you now is the same idea I have been attempting to convey to you all the time during the trial, that you are not interested or concerned here one way or the other with regard to what anybody on the outside thinks about this. It doesn't make any difference to you whether anybody is pro or con, either for the defendant or for the plaintiff. It is your business to courageously here consider this evidence and the law as the Court has given it to you and return a verdict which you think speaks the truth. I don't want you to consider or discuss anything that has not come out here in evidence. Let us have no chance of a mistrial of this case by virtue of any juror doing any independent testifying on his own account. You are entitled to apply to the solution of the question submitted to you your knowledge and experience of a lifetime, but one juror is not entitled to narrate to the other jurors some independent fact which he thinks or conceives that he knows about the matter that has not come out here in evidence, and if he has such a fact in his mind he must disregard it himself in passing upon the case.

I have had forms of verdict prepared for your convenience. In one form of verdict you will find for the plaintiff and there is a blank left in which you may insert, if you find damages. There is another blank left in which you can insert, if you find the plaintiff is entitled to it under the instructions I have given you, the amount of exemplary or punitive damages. There is another form in which you find for the defendant, Morris Fishbein. In either event your verdict must be signed by the foreman, and your verdict must be unanimous. I will let you select your own foreman.

CONCLUSION

At this point the jury withdrew from the room, while the attorneys presented their objections to the charge made by the Judge.

After about four hours the jury returned a verdict for the defendant, Dr. Morris Fishbein.

SATURDAY, JUNE 3, 1939

HEARINGS ON THE WAGNER HEALTH BILL

On May 25 and 26 representatives of the American Medical Association appeared before the subcommittee of the Senate Committee on Education and Labor in the Senate Office Building in Washington to present the point of view of the House of Delegates of the American Medical Association relative to this proposed legislation (see Proceedings of the St. Louis session, this issue, page 2295). Preliminary to the hearings, a day was given over to consideration of the material to be presented and the manner of presentation. The first statement was made by Dr. Rock Sleyster, President of the Association. Dr. Edward H. Cary, Chairman of the Legislative Committee, presented the various speakers to the Senate Committee. Dr. Walter Donaldson offered the report adopted without a dissenting vote by the House of Delegates, after which the factual data of medical care were outlined by Dr. R. G. Leland, Director of the Bureau of Medical Economics. A general statement in opposition to the Wagner Health Bill on the basis of current conditions in American medical practice was next presented by Dr. Haven Emerson of Columbia University. Hospital service in the United States was discussed by Dr. R. L. Sensenich of South Bend, Ind., a member of the Board of Trustees, and by Dr. Wingate Johnston of Winston-Salem, N. C. Dr. Milton Robb of Detroit considered the relationship of public health education to the progress of medical care, and Dr. Robert L. Benson of Portland, Ore., outlined the method of care of the indigent in Oregon. A statement prepared by Dr. Walter Vest concerning compensation for loss of wages during illness and medical service in relationship thereto was given to the committee for its consideration.

At another session Dr. Charles Gordon Heyd of New York indicated the manner in which this legislation might serve as an introductory step to a complete compulsory sickness insurance system, and the closing consideration was made by the editor of THE JOURNAL. Participating in the discussions associated with this presentation were Drs. Olin West, Secretary and General Manager of the Association; W. C. Woodward, Director of the Bureau of Legal Medicine and Legislation; W. D. Cutter, Secretary of the Council on Medical Education and Hospitals; Frank Crockett of Lafayette, Ind., member of the Legislative Committee, and Holman Taylor of Fort Worth, Texas, Secretary of the Texas State Medical Association and member of the Judicial Council of the American Medical Association.

During the course of the hearings, many senators at various times listened to the statements that were being made, including Senator Murray (Vermont), Ellender (Louisiana), Taft and Donahey (Ohio), Thomas (Utah), Holman (Ore.) and Davis (Pennsylvania). Opportunity was also afforded for members of the delegation to confer with other senators relative to the objectives of this bill. Two medical members of the Congress—Drs. Smith of Ohio and Austin of Connecticut—expressed opposition to this legislation, and Austin made a personal appearance before the committee. Congressman Smith is scheduled for a later appearance. Also on the days devoted to the hearings of the representatives of the American Medical Association there appeared Mr. Homer Folks of the New York State Charities Aid Association, who approved the bill, and Dr. C. C. Lund, who appeared in opposition on behalf of the Massachusetts State Medical Society.

During the course of the hearings Senator Wagner of New York interrogated at considerable length all the physicians who appeared, apparently endeavoring to obtain suggestions as to amendments to the measure or other means by which it might be made suitable. Large numbers of persons were in attendance and the statements made were widely disseminated in the press and over the radio. It is expected in a future issue of THE JOURNAL to present a condensed account of the statements made and the questions and answers brought out by the discussion. At this time the indications appear to be that the Wagner Health Bill will not receive final consideration during the present session of Congress.

COLOSTRIC ANTIBODIES

The demonstration by Schneider and Szathmary[1] of Budapest of an abrupt rise in specific antibody titer of the blood serum of newborn calves following the first feeding of colostrum is confirmatory evidence in support of current belief as to the mechanism of postpartum transfer of maternal immunity. Veterinarians suggested long ago for the prevention of tuberculosis the immediate separation of newborn calves from their diseased mothers in infected herds, the young to be reared by healthy foster mothers or by artificial feeding. In spite of the most careful hygienic measures, however, almost all calves thus isolated developed gastrointestinal disease, joint disease or septicemia, fully 80 per cent of them dying within the first few days. Necropsies

1. Schneider, L., and Szathmary, J.: Ztschr. f. Immunitätsforsch. 94:458, 465 (Dec.) 1938.

showed that these deaths were not due to the ordinary contagious diseases but to invasion of the living tissues with the commoner environmental saprophytes. Evidently the calf at birth is unprepared to resist invasion by numerous species of micro-organisms which do not cause recognizable disturbance in adult cattle.

Later it was demonstrated that newborn calves will remain free from saprophytic infections if allowed one natural feeding before separation from the tuberculous mothers. In this first feeding the calves do not obtain the usual milk but a specially secreted premilk or colostrum. One colostric feeding is usually sufficient to immunize a newborn calf against the usual subpathogenic environmental flora. Fully 90 per cent of all calves thus immunized may be successfully raised by artificial feeding. Veterinarians concluded from this observation that there is present in the premilk or colostrum some highly efficient hormone, enzyme, bacteriophage or other protective substance, especially designed to counteract the organisms which invade at birth. The nature of this hypothetic colostric bacteriostat is unknown, although Theobald Smith [2] and his co-workers found that calves given one or more initial feedings with normal adult cow serum acquire the same degree of postpartum immunity.

Most of the later attempts to determine the nature of this lactic substance have been directed toward the isolation and identification of hypothetic "inhibins," "lysozymes" or "transformins" [3] in normal milk. The Hungarian veterinarians, however, adopted a new method of approach, studying the specific antibody titer of both colostrum and newborn calves. Several weeks before the expected delivery, pregnant cows were immunized against both typhoid bacilli and diphtheria toxin. By the end of this duplex immunization the cows had 170 antitoxin units per cubic centimeter in their blood stream and a 1 : 100 antityphoid agglutinin titer. Samples of colostrum withdrawn at this stage showed a 1 : 5,000 agglutinin titer and 1,400 antitoxin units per cubic centimeter, an average of from ten to fifty times the antibody titer of the maternal blood. Theoretically, therefore, 1 cc. of colostrum would be the equivalent of from 10 to 50 cc. of blood serum in the oral transfer of acquired maternal immunity.

Before the first natural feeding the newborn calves showed no trace of typhoid agglutinin in the blood stream and less than 0.02 unit of diphtheria antitoxin per cubic centimeter. This confirms the conclusions of numerous previous workers, who have postulated that transplacental interchange of serum proteins does not take place because of the primitive nature of the bovine placenta. The Hungarian veterinarians found that within ninety minutes after the first feeding of colostrum the average agglutinin titer of the newborn calves had risen to 1 : 1 and the antitoxin titer to 0.25 unit per cubic centimeter of blood serum. By the end of the first twenty-four hours of normal feeding the average serologic titers of the calves was 30 per cent of that of the maternal blood. By this time the colostrum had been replaced by normal milk, which did not contain detectable traces of specific agglutinin though still containing 2 per cent of the colostrum titer of diphtheria antitoxin. By the end of two weeks this antitoxin titer had fallen to 0.97 per cent of the average concentration of colostrum, which trace of diphtheria antitoxin continued to be secreted in the milk for at least forty-five days.

The Hungarian serologists conclude from their data that colostric immunity is not due to the implantation of some esoteric hormone in the gastrointestinal tract, as previously assumed, but to a simple transfer of ordinary humoral antibodies. The mechanisms by means of which these antibodies are mobilized, concentrated or locally synthesized in the colostrum have not yet been determined. The apparently quantitative absorption of these colostric proteins from the gastrointestinal tract of newborn calves also awaits explanation. Further studies of colostric titer and rate of gastrointestinal absorption are promised for other animal species, including rodents, which have the human type of placenta.

MECHANISM OF THE INSULIN RESPONSE IN NONDIABETIC MALNOURISHED PATIENTS

Since Pitfield [1] reported in 1923 that infants suffering from inanition gained in weight and in general health following the injection of insulin, this treatment of malnutrition in nondiabetic patients has been widely used. Allen and his co-workers,[2] Blotner [3] and Ellman [4] observed the effect of insulin therapy in cases of pulmonary tuberculosis, generalized arthritis or unexplained malnutrition of adult patients. They reported improvement in appetite, in weight gained and in the general appearance of well being.

The mechanism by which insulin may bring about a better state of nutrition has not been generally understood. The theories which have been postulated include direct stimulation of the stomach or of the vagus nerves which produces hunger contractions, depression of the blood sugar level which results in increase in the hunger contractions, and improved absorption and utilization of food by increasing the amount of one or all of the

digestive juices (this hypothesis assumes that the improved appetite which has been observed following insulin therapy is secondary to the improvement in food utilization and not an effect on the stomach per se). Freyberg [5] suggested that the improvement in appetite accompanying the administration of insulin was purely psychologic.

The theory most widely accepted conceives that the increase in gastric motility and in subjective hunger sensation is directly brought about by a lowered blood sugar level which follows the administration of insulin. In 1916 Carlson [6] reported that the blood sugar level was inversely related to hunger contractions. Later, inhibition of normal hunger contractions resulting from an elevation of the blood sugar level with the intravenous administration of dextrose was reported.[7] Similar inhibition of the main stomachs of animals with Heidenhain pouches when dextrose was administered intravenously has been shown.[8] Mulinos,[9] however, was unable to find any inhibition of hunger contractions from the intravenous administration of dextrose. Quigley and Hallaran [10] confirmed the observation that dextrose did produce an inhibition of hunger contractions but reported that this lag was of only one to two minutes' duration. Motility returned immediately, though the blood continued to show hyperglycemia. Hunger contractions, these observers noted, invariably increased when the blood sugar level dropped below normal.

Scott and his co-workers [11] have reported that, within the range of experimental error, no variations in the blood sugar level of human subjects were found either preceding, during or after normal hunger periods. While this observation would justify the conclusion that the level of the blood sugar bears no causal relation to the normal "hunger periods" of man, it does not refute the evidence of many investigators [12] that hunger contractions, as evidenced by an increased motility of the empty stomach, consistently follow the injection of insulin, either intravenously or subcutaneously. This hypermotility occurs in so short a time after the injection of the insulin that it is not reasonable to assume that the primary etiologic factor is decrease in the level of the blood sugar. Wilder and Schlutz [12] demonstrated that the hypermotility which followed subcutaneous administration was rapidly abolished by atropine in doses of 0.5 mg. given subcutaneously, although the blood sugar level remained lower than that found during the insulin hypermotility of the stomach. Quigley and Halloran also showed that the insulin action increasing the motility of the empty stomach is destroyed when the vagus nerves are sectioned.

These various studies may justify the conclusion that insulin has a direct effect on gastric motility through stimulation of the vagus nerves. However, the lowering of the blood sugar level following the administration of from 12 to 20 units of insulin, as reported by Quigley,[13] may be an additional factor in increasing or prolonging gastric motility and subjective hunger sensation.

The improvement in nutrition of patients suffering from chronic debilitating diseases following the administration of insulin may nevertheless be brought about by a more complicated process than merely an increase in appetite. Okada and his colleagues [14] have demonstrated that decrease in blood sugar below the normal level does produce an increase in the amount of gastric, biliary and pancreatic secretion. Lueders and Watson [15] have reported a measurable increase in the potency of the pancreatic enzymes following the administration of insulin. They have further demonstrated a reduction of the digestive secretions and a diminution of gastric motility when dextrose is placed in the duodenum or administered intravenously. Lueders has also found evidence of improved digestion from examination of the stools of patients before and during insulin treatment.

There would seem then to be sufficient factual evidence to justify the conclusion that the mechanism of improved nutrition from insulin therapy includes direct stimulation, by way of the vagus nerve, producing increased motility and more acute subjective sensations of hunger and depression of the blood sugar below the normal level, causing additional or prolonged hunger contractions. These two factors may then be responsible for the immediate increase in appetite and willingness to partake of food which is usually manifested within fifteen to twenty minutes after the subcutaneous injection of the insulin. A third factor in the mechanism of the insulin response may be the increase in the amount of the digestive secretions, resulting in better digestion, absorption and utilization of the components in the patient's diet.

Current Comment

FRACTURE OF THE SPINE DURING METRAZOL THERAPY FOR DEMENTIA PRAECOX

In this week's issue of THE JOURNAL (page 2240) appears another contribution concerned with fracture of the spine complicating metrazol therapy. Incidentally, the paper by Bennett and Fitzpatrick was received previously to the article by Polatin and his co-workers, which was published in THE JOURNAL April 29. Obviously convulsive therapy represents a difficult technic. It is susceptible to serious complications and is therefore one that should never be undertaken except under the best of controlled conditions. The report by Bennett and Fitzpatrick, first presented at a meeting of the Boston Society of Psychiatry and Neurology on February 16, indicates that eight out of seventeen patients treated by this technic complained of backache and that each of these patients showed x-ray evidence of compressed fractures affecting the spine. In this connection, the technic for preventing this complication described by Hamsa and Bennett in this issue (page 2244) merits attention. Apparently spinal anesthesia induced prior to shock therapy may be able to prevent severe fractures of the spine and lower extremities.

BROMO-SELTZER

Under the dangerous drug section of the new Federal Food, Drug and Cosmetic Act, the Food and Drug Administration has initiated action against Bromo-Seltzer. . This prompt action against a large manufacturer indicates a desire to enforce the laws equally on all violators. Bromo-Seltzer, which is an acetanilid-bromide preparation, is alleged by the government to be misbranded "in that it is dangerous to health and because of the failure of the labeling to reveal facts material with respect to the consequences which may result from the use of the article and the failure to bear warnings against use in those pathological conditions, or by children where its use may be dangerous to health, or against unsafe dosage, or methods, or duration of administration, in such manner and form as are necessary for the protection of users." The allegations are based on provisions that went into effect last June. Similar provisions against dangerous drugs were not contained in the Food and Drugs Act of 1906 as amended. The Emerson Drug Company has indicated that it will contest the action of the Food and Drug Administration. In its answer to the charges, the concern denies that Bromo-Seltzer is dangerous. It states that it has been used for many years by millions of people without injurious results. The lack of scientific basis for these statements is evident to those who consult the scientific medical literature. Since 1906 THE JOURNAL has carried repeated references to injury from Bromo-Seltzer. The manufacturers have lately conducted a vigorous advertising campaign in what seems to be a wofully inadequate attempt to "build up" acetanilid without pointing out dangers that arise from its indiscriminate use. To provide a front of scientific plausibility, this exploitation utilizes a number of scientific studies which seem to have little or no bearing on the fundamental objections to Bromo-Seltzer. Presumably the large resources of the Emerson Drug Company will be made available in the contest of this issue. No doubt the Food and Drug Administration will present the scientific justification for the allegations in the stipulation. The case will be a test of what may be anticipated in the way of public protection from the new drug act.

THE PROCEEDINGS OF THE BRINKLEY TRIAL

In this issue of THE JOURNAL appears the final instalment of the proceedings of the case of *Brinkley* v. *Fishbein*, in which the verdict was awarded by the jury to the editor of *Hygeia*. Most significant is the charge of Judge R. J. McMillan to the jury which rendered the verdict in this case. The entire charge merits most careful consideration; indeed, some of the statements might well be read to the senior class of every medical college in this country. Particularly to be considered is that section of the charge dealing with medical ethics. Here the judge said, and it is repeated for emphasis:

> In determining what is professional and not professional conduct of the physician, you may take into consideration the rules of ethics followed by the great majority of medical men and which are recognized generally in their profession. . . . The term as applied to the liberal professions, such as the practice of medicine or the practice of law, is generally understood to mean that course of conduct pursued by recognized moral practitioners either of medicine or law.
>
> It doesn't necessarily follow that every slight deviation or change by a doctor or a lawyer from what the general body of the doctors or lawyers do would be unethical, but if his course of conduct was far beyond and contrary to the course of conduct which the other members of his profession followed, then you would say that he was unethical either in the practice of medicine or in the practice of law.
>
> As the evidence here shows, it has practically always been considered unethical for physicians to advertise, that is to say, to advertise further than to call the attention of the public to the fact that they were there ready to practice, and by some character of card giving their location or address, or if they specialize in some particular kind of practice to so advise the public. Advertisements by which prizes are offered to secure patronage or by which claims are made of superior skill or ability are not ethical, and you may consider those matters in this case in passing on the question as to the truth or falsity of the charge. In other words, it is one of the component elements that go to make up the question as to whether this man would be classified as a quack or not. It is not entirely determinative, but it may be that it is entitled to consideration. Accordingly, in determining what is professional and unprofessional conduct by a physician you are entitled to take into consideration the rules of ethics followed by the great majority of the medical men and which are generally recognized in their profession. The conduct of the plaintiff Brinkley should not be measured against his own personal ideas with regard to what is proper. It should be measured against the ethics and approved conduct of physicians generally, and to such extent that his conduct as a physician varies from the rules of ethics recognized and observed generally he becomes subject to criticism, and criticism of his conduct is privileged unless unduly excessive and the terms of the criticism are unreasonable or unfair.

Thus a Federal Court has recognized the significance of medical ethics for the protection of the public, and the jury after due consideration placed its approval on the right of the public to have the protection that medical ethics affords.

ORGANIZATION SECTION

PROCEEDINGS OF THE ST. LOUIS SESSION

MINUTES OF THE NINETIETH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION, HELD AT ST. LOUIS, MAY 15-19, 1939

(Concluded from page 2178)

HOUSE OF DELEGATES

Third Meeting—Wednesday Afternoon, May 17

The House of Delegates was called to order at 1:50 p. m. by the Speaker, Dr. H. H. Shoulders.

Presentation of Minutes

It was moved by Dr. Arthur T. McCormack, Kentucky, seconded by Dr. J. Newton Hunsberger, Pennsylvania, and carried, that the House dispense with the reading of the minutes.

Report of Reference Committee on Legislation and Public Relations

Dr. Holman Taylor, Chairman, presented a report of the Reference Committee on Legislation and Public Relations, which, as amended, reads as follows:

The report of the Committee on Legislative Activities covers in an informative manner two principal items of concern to the medical profession, namely the Veterans' Administration and medical relief through the Farm Security Administration. Your reference committee has considered these matters and wishes to report as follows:

1. Veterans' Administration: It is clear from the history and the statistics cited in the report that the purpose of the Veterans' Administration is primarily that of providing adequate accommodations for veterans entitled to medical and hospital service. It is anticipated that the peak of requirement of medical service will be reached in 1949 or 1950. A steady increase in available hospital beds will be incurred until that time. The profession is now in no position to object to the present rate of increase. We are advised that the Veterans' Administration has heretofore given due consideration to the counsel of our liaison groups, of whatsoever makeup, and that there has been no particular embarrassment between them. It is our information that the present contention of those in authority at Washington is that after the peak of demand has passed the surplus hospital beds shall be used for the domiciliary care of veterans not able to provide for themselves. It is the opinion of your committee at this time that this would be the proper use to make of these facilities. Your committee, however, would call the attention of this House of Delegates to the ease of conversion of veterans' hospitals into hospitals for the care of the public in general under some plan of socialized medicine. There seems to be no recommendation that can be advantageously made in this connection at this time.

2. Medical Relief Through Farm Security Administration: The report is very clear and specific in dealing with this problem. It occurs to your reference committee that the main requirement in this matter is a better understanding with the Farm Security Administration and a very definite coordination of effort between county and state medical associations, under the advice and counsel of the Bureau of Medical Economics of the American Medical Association. At the present time the practice of the Farm Security Administration is to make an agreement for medical service either with county medical societies or with state medical associations, as convenience may dictate. Your committee is advised, however, that the Farm Security Administration would prefer dealing with state medical associations primarily and with county medical societies secondarily. Your reference committee recommends that all agreements for medical service under the Farm Security Administration should be made with county medical societies under master agreements with the state medical associations, and that in such agreements the metes and bounds from the angle of medical ethics and medical economics should be set up. In order that there may be coordination of effort and uniform observance of the economic and ethical factors involved, it is further recommended that county medical societies send two copies of their respective agreements to their respective state medical associations, one of which should be forwarded to the Bureau of Medical Economics of the American Medical Association. The Trustees are requested to provide through the Bureau of Medical Economics for such statistical and other information as may be of service to state medical associations and county medical societies. The procedure recommended here should be looked on as an opportunity rather than a requirement.

There are many reasons why some effort should be made to direct developments in the matter of medical service for Farm Security Administration clients and similar groups. The procedures involved furnish an admirable setup for very objectionable practices in the direction of socialized medicine, so called. Under the agreements involved in the system, no practice should be allowed which is objectionable from the angle of socialized medicine. These practices have all been definitely and clearly set out in various pronouncements of the House of Delegates of the American Medical Association. Certainly, there should be freedom of choice of physician, and certainly there should be no intervention of a third party, between the patient and his physician; neither should there be any direction by any agent of the government as to the nature of treatment to be accorded the patient by his physician. It will be appreciated that in the present state of the changing order there will likely be changes in economic and ethical factors involved, which will accentuate all the greater necessity for close supervision of such matters.

Your reference committee heartily commends the announced attitude of the American Farm Bureau Federation, as preservative of the practice of medicine as we know it and as we believe our people want it.

Respectfully submitted.

HOLMAN TAYLOR, Chairman.
L. G. CHRISTIAN.
K. S. J. HOHLEN.
THOMAS P. FARMER.
G. HENRY MUNDT.

The report of the reference committee was adopted as amended on motion of Dr. Taylor, duly seconded and carried.

Report of the Reference Committee on Reports of Officers

Dr. William H. Myers, Georgia, presented the following supplementary report:

Teaching in Schools of Chiropody or Podiatry: Your reference committee approves the position taken by the Judicial Council in its supplementary report with regard to teaching the subjects of chiropody or podiatry.

Respectfully submitted.

FLOYD S. WINSLOW, Chairman.
WILLIAM H. MYERS.
JAMES Q. GRAVES.
ELBRIDGE J. BEST.
FORREST J. PINKERTON.

Dr. Myers moved that the report be adopted and the motion was seconded by Dr. Arthur J. Bedell, Section on Ophthalmology.

After discussion, it was moved that the report of the reference committee be laid on the table. The motion was seconded by Dr. Felix J. Underwood, Mississippi, and carried.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John H. Fitzgibbon, Chairman, presented the following report:

In order to consider adequately the correspondence with the National Medical Association, Inc., referred to this committee by the House of Delegates on May 15, your reference committee arranged a conference with official representatives of that association, namely Drs. Carl G. Roberts, Roscoe C. Giles and Clarence H. Payne.

These representatives have brought to your committee's attention certain problems which it is mutually agreed must be considered as inimical to the welfare of colored physicians and the people whose medical welfare they have at heart. Among these problems are:

1. The erroneous impression created by publicity bearing on the question of membership in the American Medical Association.

2. Certain discriminatory attitudes said to exist which deny to competent members of the colored profession participation in governmentally directed health projects involving medical service to the patients of colored physicians.

With respect to the matter of membership in the American Medical Association, your committee desires to reemphasize the fact that membership in the various component county societies should not be denied to any person solely on the basis of race, color or creed. Attention is called to the fact that there are now a large number of colored physicians in the membership of the American Medical Association whose qualifications meet the professional requirements.

Notwithstanding the broad principle referred to, it is recognized that every component county medical society has the right of self government in local matters and membership.

Your reference committee desires to speak with emphasis regarding discrimination against any competent and qualified physician, regardless of race, color or creed, which interferes with his right as a physician to serve those who desire to consult him. This House of Delegates has consistently gone on record as insisting on the right of the citizen to choose his own physician and your reference committee feels that no discrimination should be tolerated.

Respectfully submitted.

John H. Fitzgibbon, Chairman.
J. Newton Hunsberger.
Grant C. Madill.
Charles W. Roberts.
W. F. Braasch.

Dr. Fitzgibbon moved that the report of the reference committee be adopted, and the motion was second by Dr. Charles W. Roberts, Georgia.

After discussion, it was moved by Dr. John M. Birnie, Massachusetts, seconded by Dr. James E. Paullin, Section on Practice of Medicine, that the report of the reference committee be rereferred to the Board of Trustees for clarification and resubmission to the House at this session.

Report of Reference Committee on Miscellaneous Business

Dr. Henry C. Macatee, Chairman, presented the following report, which was adopted on motion of Dr. Macatee seconded by Dr. A. T. McCormack, Kentucky, and carried.

Your reference committee recommends that the resolutions dealing with the Army Medical Museum and Library submitted by Dr. H. C. Macatee, District of Columbia, be amended by substituting the words "the House of Delegates of the American Medical Association" for the words "the Medical Society of the District of Columbia," and by omitting the last paragraph.

Your reference committee recommends the adoption of the resolution in accordance with its suggested amendments.

Respectfully submitted.

Henry C. Macatee, Chairman.

Report of Reference Committee on Amendments to Constitution and By-Laws

Dr. Charles E. Mongan, Chairman, presented the following report:

1. Resolutions Proposing Amendments to the By-Laws Governing the Council on Medical Education and Hospitals: Your reference committee has given these resolutions a great deal of consideration. On Tuesday, May 16, 1939, a hearing was held, which was attended by the President, the President-Elect, the Secretary and many Fellows of the American Medical Association. At this well attended meeting the matter was fully presented and the importance of the Council on Medical Education and Hospitals was fully demonstrated. Its work seems to be well in hand and admirably executed. All phases of the question that had been presented at the hearing of the committee were gone over in executive session. The evidence for the proposed change in the By-Laws of this organization was well weighed.

Your reference committee has come to the conclusion that the Council on Medical Education and Hospitals, as provided for in the By-Laws, is working most auspiciously for the welfare of the American Medical Association, for medical education and for security of the public.

Your reference committee does not, therefore, recommend the amending of the By-Laws by the adoption of the proposed resolutions.

2. Resolution on Prescribing of Radium: After careful consideration of the subject matter of the resolution and the action of the House of Delegates of the American Medical Association in 1938 at which the recommendation of the Judicial Council was approved, your reference committee believes that a careful reading of the report of the Judicial Council, which was to the effect that a physician prescribing for a patient without examining the said patient is performing an unethical act, will show that there was nothing expressed in the opinion of the Judicial Council regarding the owning or leasing of radium other than the relationship of the lessor to the user of the radium.

Your reference committee would invite the careful attention of each member of the House of Delegates to the exact wording of the resolution adopted by the House of Delegates in the 1938 session.

Your reference committee reiterates the language of the report of the Reference Committee on Amendments to the Constitution and By-Laws in 1938, which read as follows: "After due consideration of the matter, your committee feels that the phraseology should remain. Any exceptions to the general principle involved would defeat its purpose."

Your reference committee recommends, therefore, that the resolution presented by the Illinois State Medical Society be not adopted.

Respectfully submitted.

Charles E. Mongan, Chairman.
Edgar A. Hines.
T. K. Gruber.
Felix P. Miller.
E. G. Wood.

Dr. Mongan moved the adoption of Section 1 of the report of the reference committee, recommending that the By-Laws be not amended in accordance with the resolutions. The motion was seconded by Dr. H. B. Everett, Tennessee, and lost after discussion.

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. Arthur J. Bedell, Section on Ophthalmology, and

carried, the first section of the report of the reference committee was rereferred to that committee for further consideration and subsequent report.

The second section of the report of the reference committee, dealing with the resolution on the prescribing of radium, was adopted on motion of Dr. Mongan, seconded by Dr. Harvey F. Garrison, Mississippi, and carried.

Proposed Amendment to the Constitution

Dr. George Edward Follansbee, Chairman, Judicial Council, presented the following proposed amendment to the Constitution, which must lay over until the 1940 session for action:

Resolved, That the Constitution of the Association be amended by the insertion of the words "holding the title Doctor of Medicine or Bachelor of Medicine" between the words "associations" and "are" in article 8, section 1, third line.

Executive Session—Wednesday Afternoon, May 17

A motion to permit county and state officers vouched for by the delegates from the respective states and representatives of certain organizations interested, as well as the administrative personnel of the American Medical Association, to attend the Executive Session was duly seconded and carried.

The Sergeants-at-Arms polled the House, after which the House went into Executive Session at 3:30 p. m., with Dr. H. H. Shoulders, Speaker, presiding.

Report of Reference Committee on Consideration of the Wagner National Health Bill

Dr. Walter F. Donaldson, Chairman, presented the following report, which was adopted without a dissenting vote, on motion of Dr. Donaldson, seconded by Dr. H. B. Everett, Tennessee, and carried:

Your reference committee has carefully considered the bill designated as S. 1620, "A Bill to provide for the general welfare by enabling the several states to make more adequate provision for public health, prevention and control of disease, maternal and child health services, construction and maintenance of needed hospitals and health centers, care of the sick, disability insurance and training of personnel; to amend the Social Security Act; and for other purposes."

History of Wagner Health Bill

This bill was introduced by Senator Robert F. Wagner of New York, Feb. 28, 1939, and is commonly referred to as the Wagner Health Bill. The bill itself provides that, if it is enacted, it may be cited as the "National Health Act of 1939." The purposes of the bill are sufficiently stated in the title, but the bill itself must be recognized as a proposed amendment to the Social Security Act of 1935. The bill is intended to make effective a national health program recommended by the Interdepartmental Committee to Coordinate Health and Welfare activities.

The House of Delegates of the American Medical Association, at its special session in Chicago, Sept. 16 and 17, 1938, adopted five recommendations made by a special committee that had been appointed to consider and report on the National Health Program. It is important that this fact be borne in mind, for the bill now under consideration, which was drafted long after those recommendations were adopted and at a time when they were presumably known to the proponents of this bill, does not recognize either the spirit or the text of those recommendations. Any criticism of this bill by the Association is not to be construed, therefore, as a repudiation of any of the principles adopted at the 1938 special session of the House of Delegates.

Analysis of the Bill

S. 1620 proposes to amend title V of the Social Security Act —Grants to States for Maternal and Child Welfare—and title VI—Public Health Work and Investigations—and proposes to add to the Social Security Act certain new titles: namely, title XII—Grants to States for Hospital and Health Centers; title XIII—Grants to States for Medical Care, and title XIV—Grants to States for Temporary Disability Compensation.

Already some individuals and organized groups in the United States have appeared before the Senate subcommittee which has this bill under consideration and have urged its immediate enactment. Although the stated objectives of the Wagner Health Bill are generally recognized as desirable, your committee cannot approve the methods by which these objectives are to be attained.

Repeatedly, physicians and all other qualified professional groups have recommended the coordination and consolidation of the health activities of the federal government. The Wagner Health Bill leaves existing and proposed preventive and curative medical services widely scattered through several federal agencies.

This bill does not in any way safeguard the continued existence of the private practitioners who have always brought to the people the benefits of scientific research and treatment.

It does not provide for the use of the thousands of vacant beds now available in hundreds of church and community general hospitals.

The Wagner Health Bill proposes an extensive program in the field of "health, diagnostic and treatment centers, institutions and related facilities," without defining their functions.

This bill proposes to make federal aid for medical care the rule rather than the exception, since it does not specifically limit its benefits to persons unable to pay for adequate medical care.

The Wagner Health Bill does not recognize the need for suitable food, sanitary housing and the improvement of other environmental conditions necessary to the continuous prevention of disease and promotion of health.

This bill insidiously promotes the development of a complete system of tax supported governmental medical care, thus undermining and debasing present standards of medical services.

The House of Delegates in September 1938 urged compensation for the loss of wages during sickness. The Wagner Health Bill deviates from this suggestion by proposing to provide medical services in addition to compensation.

The Wagner Health Bill would authorize an enormous expansion of governmental medical services and therewith ultimately unlimited appropriations for its health program. The funds necessary would be so great as to increase still further the present burdensome general taxation.

The Wagner Health Bill provides for supreme federal control. Rules and regulations must be promulgated by the Chief of the Children's Bureau in the Department of Labor, the Surgeon General of the Public Health Service, the Federal Emergency Administrator of Public Works, and the Social Security Board. These federal agents are given authority to disapprove plans proposed by the individual states.

The House of Delegates at its September 1938 session approved the expansion of preventive and other medical services when the need could be shown. The Wagner Health Bill prescribes no method for determining the nature and extent of the needs for which it proposes allotments of funds.

The provisions in the Wagner Health Bill that have never been considered by the House of Delegates are the authorization of appropriations for studies, investigations and demonstrations, and the creation of federal and state advisory councils.

Conclusions

The Wagner Health Bill, as judged by the considerations that have been here presented, is inconsistent with the fundamental principles of medical care established by years of scientific professional medical experience, and in the opinion of your committee it is therefore contrary to the best interests of the American people.

For years the health of the people of the United States, as measured by sickness and death rates, has been better than that of most foreign countries, and this improvement has been continuous. The fortunate health conditions in the United States

cannot be dissociated from the standards and methods of medical practice that have prevailed under the present system of medical practice.

No other profession and no other organization have done more for the prevention of disease, the promotion of health and the care of the sick than have the medical profession and the American Medical Association. No other groups have shown more genuine sympathetic interest in human welfare.

The contribution of the individual members of the American Medical Association to medical care is universally regarded as monumental in total volume. The contribution of the American Medical Association, through a program of medical education and the activities of its numerous councils which safeguard medical service, gives abundant proof of interest in the problems of the national health. It has given continued consideration to these problems, whereas others show concern with these proposals because of a present but, it is to be hoped, a temporary need for relief. These are the groups which request revolutionary legislative action as indispensable for the extension and further diffusion of health facilities.

In view of its record and in consideration of the responsibility which American social history and the nature of medical care have imposed on the medical profession, the American Medical Association would fail in its public trust if it neglected to express itself unmistakably and emphatically regarding any threat to the nation's health and well-being.

The American Medical Association must therefore, speaking with professional competence, oppose the Wagner Health Bill.

RECOMMENDATIONS

Nevertheless, recognizing the soundness of the principles stated in the recommendations adopted by the House of Delegates at its special session in 1938, namely the expansion of preventive medicine and public health where need can be shown, the extension of medical care for the indigent and the medically indigent where the need can be demonstrated, with local determination of needs and local control of measures to supply these needs, your committee would urge the development of a mechanism for meeting these needs within the philosophy of the American form of government and without damage to the quality of medical services.

This question, as it relates to the aid to be given by an individual state to its own counties, municipalities or other local political units, is not immediately before this Association. The answer is to be found in the individual state constitutions and state statutes. Counties, townships and municipalities are creatures of the individual states and can be molded and guided by the state for its own purposes. The individual state, itself, is not a creature of the federal government. The federal government is, as a matter of fact, a creature of the individual states.

The fundamental question is how and when a state should be given financial aid by the federal government out of the resources of the states as a whole, pooled in the federal treasury. Disasters such as floods, dust storms, fire and epidemics have long been recognized as justifying such federal aid. No state or person has ever been heard to object to the use of funds out of the federal treasury for such purposes. No one has ever proposed however that, because federal aid is extended under such conditions to a state in distress, a corresponding aid must be extended to every other state regardless of its need. Nor has any one ever been heard to say that federal aid to a state in distress, because of flood, dust storm, fire or epidemic, shall not be extended unless and until the suffering state has produced from its own treasury a stated amount of money to aid in affording the relief. The development of such bizarre thinking may be traced to those who have originated within comparatively recent years the granting of federal subsidies—sometimes referred to as "grants in aid"—to induce states to carry on intrastate activities suggested frequently in the first instance by officers and employees of the federal government. The use of federal subsidies to accomplish such federally determined activities has invariably involved federal control. Any state in actual need of financial aid from the federal government for the prevention of disease, the promotion of health and the care of the sick should be able to obtain aid in a medical emergency without stimulating every other state to seek and to accept similar aid and thus to have imposed on it the burden of federal control.

The mechanism by which this end is to be accomplished, whether through a federal agency to which any state in need of federal financial assistance can apply or through a new agency created for this purpose or through responsible officers of existing federal agencies, must be developed by the Executive and the Congress, who are charged with these duties. Such method would afford to every state an agency to which it might apply for federal assistance to enable it to care for its own people without involving every other state in the Union or the entire government in the transaction and without disturbing permanently the American concept of democratic government.

SUMMARY

1. The Wagner Health Bill does not recognize either the spirit or the text of the resolutions adopted by the House of Delegates of the American Medical Association in September 1938.

2. The House of Delegates cannot approve the methods by which the objectives of the National Health Program are to be obtained.

3. The Wagner Health Bill does not safeguard in any way the continued existence of the private practitioners who have always brought to the people the benefits of scientific research and treatment.

4. The Wagner Health Bill does not provide for the use of the thousands of vacant beds now available in hundreds of church and community general hospitals.

5. This bill proposes to make federal aid for medical care the rule rather than the exception.

6. The Wagner Health Bill does not recognize the need for suitable food, sanitary housing and the improvement of other environmental conditions necessary to the continuous prevention of disease.

7. The Wagner Health Bill insidiously promotes the development of a complete system of tax supported governmental medical care.

8. While the Wagner Health Bill provides compensation for loss of wages during illness, it also proposes to provide complete medical service in addition to such compensation.

9. The Wagner Health Bill provides for supreme federal control; federal agents are given authority to disapprove plans proposed by the individual states.

10. The Wagner Health Bill prescribes no method for determining the nature and extent of the needs for preventive and other medical services for which it proposes allotments of funds.

11. The Wagner Health Bill is inconsistent with the fundamental principles of medical care established by scientific medical experience and is therefore contrary to the best interests of the American people.

12. The fortunate health conditions which prevail in the United States cannot be dissociated from the prevailing standards and methods of medical practice.

13. No other profession and no other group have done more for the improvement of public health, the prevention of disease and the care of the sick than have the medical profession and the American Medical Association.

14. The American Medical Association would fail in its public trust if it neglected to express itself unmistakably and emphatically regarding any threat to the national health and well being. It must therefore, speaking with professional competence, oppose the Wagner Health Bill.

15. The House of Delegates would urge the development of a mechanism for meeting the needs for expansion of preventive medical services, extension of medical care for the indigent and the medically indigent, with local determination of needs and local control of administration, within the philosophy of the American form of government and without damage to the quality of medical service.

16. The fundamental question is how and when a state should be given financial aid by the federal government out of the resources of the states as a whole, pooled in the federal treasury.

17. The bizarre thinking which evolved the system of federal subsidies—sometimes called "grants-in-aid"—is used to induce states to carry on activities suggested frequently in the first instance by officers and employees of the federal government.

18. The use of federal subsidies to accomplish such federally determined activities has invariably involved federal control.

19. Any state in actual need for the prevention of disease, the promotion of health and the care of the sick should be able to obtain such aid in a medical emergency without stimulating every other state to seek and to accept similar aid, and thus to have imposed on it the burden of federal control.

20. The mechanism by which this end is to be accomplished, whether through a federal agency to which any state in need of federal financial assistance can apply, or through a new agency created for this purpose or through responsible officers of existing federal agencies, must be developed by the Executive and the Congress, who are charged with these duties.

21. Such a method would afford to every state an agency to which it might apply for federal assistance without involving every other state in the Union or the entire government in the transaction.

22. Such a method would not disturb permanently the American concept of democratic government.

Respectfully submitted.

WALTER F. DONALDSON, Chairman.
FREDERIC E. SONDERN.
WALTER E. VEST.
FRED W. RANKIN.
E. H. CARY.
HENRY A. LUCE.
HOWARD L. SNYDER.

On motion of Dr. E. L. Merritt, Massachusetts, seconded by Dr. Holman Taylor, Texas, and Dr. Virgil E. Simpson, Kentucky, and carried, a rising vote of thanks was extended by the House to the committee for the excellent work done.

On motion of Dr. H. A. Luce, Michigan, seconded by Dr. Peter Irving, New York, and carried, the House arose from Executive Session at 4:05 p. m.

The Speaker stated that the House had proceeded with the regular order of business prior to the Executive Session because the Reference Committee on Consideration of the Wagner National Health Bill had not been ready to report.

Dedication of Ephraim McDowell-Jane Todd Crawford Memorial Home

Dr. Irvin Abell, Retiring President, invited the members of the House of Delegates to attend the dedication of the Ephraim McDowell-Jane Todd Crawford Memorial Home at Danville, Ky., on Saturday, May 20, at 2 p. m.

On motion of Dr. William H. Myers, Georgia, seconded by several delegates and carried, the House recessed at 4:10 p. m.

Fourth Meeting—Thursday Afternoon, May 18

The House of Delegates was called to order at 1:15 p. m. by the Speaker, Dr. H. H. Shoulders.

Report of Reference Committee on Credentials

Dr. Deering G. Smith, Chairman, stated that a total of 168 delegates had been seated.

Roll Call

The Secretary called the roll and announced that more than a quorum had responded.

Presentation of the Minutes

It was moved by Dr. A. T. McCormack, Kentucky, seconded by Dr. George W. Kosmak, New York, and carried, that the House dispense with the reading of the minutes.

Report of Board of Trustees

Dr. A. A. Hayden, Secretary of the Board, at the request of its Chairman, Dr. Arthur W. Booth, presented a report, which as amended reads as follows:

With reference to the report of the Reference Committee on Reports of Board of Trustees and Secretary referred to the Board of Trustees for clarification, it is recognized that every component county medical society has the right of self government in local matters, including membership, by which arrangement many Negro physicians now hold membership in the American Medical Association.

Respecting governmentally directed health projects, the Board of Trustees emphatically deprecates discrimination against any competent and qualified physician because of race, color, creed or sex, which interferes with his right as a physician to serve those who desire to consult him.

The report of the Board of Trustees was adopted as amended on motion of Dr. John Q. Myers, North Carolina, seconded by Dr. McLain Rogers, Oklahoma, and carried after discussion.

Presentation of Dr. L. E. LeSouef

The Secretary presented to the House Dr. L. E. LeSouef, President-Elect of the West Australian Branch of the British Medical Association, a member of the Federal Council of the British Medical Association of Australia and a delegate for Australia to the International Congress on Military Medicine and Pharmacy at Washington, and the Chairman, representing the House, extended cordial greetings to Dr. LeSouef.

Report of Reference Committee on Amendments to the Constitution and By-Laws

Dr. Charles E. Mongan, Chairman, presented the following report, which, on motion of Dr. Mongan, seconded by Dr. John Z. Brown Sr., Utah, and carried after discussion, was adopted:

In regard to the resolutions offered by Dr. J. E. Paullin, Section on Practice of Medicine, proposing amendments to the By-Laws dealing with the Council on Medical Education and Hospitals, your reference committee proposes that the By-Laws be amended as follows: Amend chapter VIII, section 1, beginning with the sentence "The Council on Medical Education and Hospitals," line 4, page 19, and ending at the period in the ninth line on page 20 to read as follows: The Council on Medical Education and Hospitals shall consist of nine members each elected for nine years, one being elected each year: Provided three members be elected in 1940, one for nine years, one for eight years and one for seven years, and provided that the present members of the Council on Medical Education and Hospitals be continued as members until the terms for which they were elected shall have expired. The members of the Council shall be elected by the House of Delegates on nomination by the Board of Trustees, provided that the Board of Trustees shall place in nomination the names of three Fellows of the American Medical Association for each position. The members of the Council shall not be eligible for reelection. The Board of Trustees shall make their choice on the basis of securing for membership on the Council representation from general medical practice, special medical practice, medical education and graduate medical education. This Council shall prepare each year a report of its work and its recommendations, which shall be submitted to the House of Delegates.

Amend chapter IX, sec. 2, line 4, page 23, by inserting after the words "medical education" the words "including premedical, undergraduate and graduate medical education."

Respectfully submitted.

CHARLES E. MONGAN, Chairman.
T. K. GRUBER.
E. G. WOOD.
EDGAR A. HINES.
FELIX P. MILLER.

After the report of the reference committee was adopted, Dr. Mongan moved that the By-Laws be amended in accordance with the recommendation in the report of the reference committee. The motion was seconded and carried.

Report of Reference Committee on Reports of Board of Trustees and Secretary

Dr. John H. Fitzgibbon, Chairman, presented the following report, which was adopted on motion of Dr. Fitzgibbon, seconded by Dr. John Z. Brown Sr., Utah, and carried:

Your reference committee wishes to commend the report of the Committee on Medical Care. It believes that Dr. Leland and his associates deserve much credit for their able efforts in carrying out this survey and that the efforts and expenditure have been justified by the results.

Your reference committee agrees with the Committee on Medical Care as to the desirability of continuing this survey or making similar surveys in the future as the Board of Trustees may decide.

Your reference committee recommends that a brief summary of the results of the survey be published as soon as possible in the Organization Section of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

Respectfully submitted.

JOHN H. FITZGIBBON, Chairman.
J. NEWTON HUNSBERGER.
GRANT C. MADILL.
CHARLES W. ROBERTS.
W. F. BRAASCH.

ELECTION OF OFFICERS

The Speaker declared the next order of business to be the election of officers.

Election of President-Elect

Dr. Edward R. Cunniffe, New York, nominated for President-Elect Dr. Nathan B. Van Etten, New York, and the nomination was seconded by Drs. A. A. Walker, Alabama; John Q. Myers, North Carolina; E. G. Wood, Tennessee; J. Newton Hunsberger, Pennsylvania; H. A. Luce, Michigan; James E. Paullin, Section on Practice of Medicine; E. H. Cary, Texas; Arthur J. Bedell, Section on Ophthalmology; William R. Moloney Sr., California; Felix J. Underwood and Harvey F. Garrison, Mississippi; Walter E. Vest, West Virginia; Robert A. Peers, California; A. T. McCormack, Kentucky; W. F. Draper, United States Public Health Service; John Z. Brown Sr., Utah; Fred Moore, Iowa; Joseph F. Smith, Wisconsin, and Henry Cook Macatee, District of Columbia.

Dr. John Q. Myers, North Carolina, moved that the nominations be closed and that the Secretary be instructed to cast the unanimous ballot of the House of Delegates for Dr. Nathan B. Van Etten, and the motion was seconded by Drs. H. B. Everett, Tennessee, and A. T. McCormack, Kentucky, and carried.

The Secretary cast the unanimous ballot of the House for Dr. Nathan B. Van Etten, New York, for President-Elect of the American Medical Association, and the Speaker declared Dr. Van Etten so elected.

Election of Vice President

The Speaker announced that nominations for Vice President were in order and Dr. Harvey F. Garrison, Mississippi, placed in nomination the name of Dr. Alphonse McMahon, St. Louis. The nomination was seconded by Dr. A. T. McCormack, Kentucky.

Dr. H. A. Luce, Michigan, nominated Dr. Louis J. Hirschman, Detroit, and the nomination was seconded by Dr. C. R. Keyport, Michigan.

On motion of Dr. A. T. McCormack, Kentucky, seconded by Dr. John Q. Myers, North Carolina, and carried, the nominations were closed.

The Speaker asked the tellers to spread the ballot, and the Secretary announced that 147 delegates had been reported present and that 135 votes had been cast, of which Dr. Alphonse McMahon, St. Louis, received 93 and Dr. Louis J. Hirschman, Detroit, 42.

The Speaker declared that Dr. Alphonse McMahon, St. Louis, having received the majority of the votes cast, was elected Vice President of the American Medical Association, and on motion of Dr. H. A. Luce, Michigan, seconded by Dr. George W. Kosmak, New York, and carried unanimously, the action was declared unanimous.

Address of President-Elect Nathan B. Van Etten

Dr. E. R. Cunniffe, New York, presented the President-Elect of the American Medical Association, who addressed the House as follows:

Mr. Speaker, Members of the House of Delegates:

The friendly expression of this House is deeply appreciated. You have conferred on me the highest honor that can be given to an American physician. Through long association with you I am well acquainted with the strength of character and maturity of judgment which you usually maintain. After choosing a long line of the most distinguished specialists for your presidency, I fear that you are slipping a little when your choice falls on a general practitioner. Perhaps you are thinking that when the distinguished psychiatrist who is now our President finishes his psychoanalysis you may want a general practitioner to administer the treatment.

I have never aspired to this office because I have always known that many of my contemporaries are vastly more competent. I have also been led to an apprehension concerning my personal safety. Last January Dr. Sleyster left the security of the wilds of Wisconsin for a visit to the dangerous city of New York. He was heavily armed against the dangers which lurk around every corner. At the end of his visit he warned me against future perils. He put his hand in his hip pocket and presented me with one of his guns, which I always carry. He says that it is the latest streamline 1939 model and he made it himself (a slingshot). You see that if anybody brings a criminal indictment against me I am fully prepared.

Yesterday you adopted a report defining your position in relation to the proposed Wagner Health Bill. It was one of the best reports ever presented to this House. It defines our position and we must stand on it. It will have small value, however, unless the whole medical profession of the United States is educated to understand it fully. Every delegate must realize his official obligation as never before and carry home to every single practitioner in his state a full consciousness of the importance of this declaration of principles. That practitioner is potentially one of the most powerful persons in the democracy. If he can be made to see his duty to his country and educate his patients to a realization of the dangers of centralized control of medical practice, your action of yesterday will be sustained.

Gentlemen of the House, in the name of welfare the practice of medicine as you know it and as you hoped it would become is to be destroyed. The functions of the most highly educated group of professionals in the world are to be taken over by bureaus operated by adventurous amateurs. The time has come for the concerted action of every doctor in the United States. Wishful thinking on the part of you leaders of medicine will not be enough; every one must do his duty.

Election of Secretary

Dr. William R. Brooksher, Arkansas, nominated Dr. Olin West, Chicago, to succeed himself as Secretary, and the nomination was seconded by Dr. A. T. McCormack, Kentucky. Dr. McCormack moved that the nominations be closed and that the Vice Speaker be authorized to cast the ballot of the House for Dr. Olin West as Secretary. The motion was seconded by Dr. H. B. Everett, Tennessee, and by several other delegates, and carried unanimously.

The Vice Speaker cast the unanimous ballot of the House for Dr. Olin West as Secretary of the American Medical Association, and the Speaker declared Dr. West so elected for the ensuing year.

Election of Treasurer

Dr. Austin A. Hayden, Secretary of the Board of Trustees, reported that the Board desired to place before the House of Delegates the nomination of Dr. Herman L. Kretschmer, Chicago, for reelection as Treasurer of the Association.

It was moved by Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. George W. Kosmak, New York, and carried, that the nomination be confirmed, and the Speaker declared Dr. Herman L. Kretschmer elected Treasurer of the American Medical Association for the ensuing year.

Election of Speaker of the House of Delegates

Dr. R. W. Fouts, Vice Speaker, took the chair and declared the next order of business to be the election of Speaker of the House of Delegates.

Dr. E. G. Wood, Tennessee, nominated for reelection as Speaker of the House of Delegates Dr. H. H. Shoulders, Nashville, Tenn., and the motion was seconded by Drs. H. B. Everett, Tennessee; A. A. Ross, Texas; Harvey F. Garrison, Mississippi; C. R. Keyport, Michigan; John Z. Brown Sr., Utah; John Q. Myers, North Carolina, and others.

Dr. W. Albert Cook, Oklahoma, moved that nominations be closed and that the Secretary be instructed to cast the ballot for Dr. H. H. Shoulders, Nashville, Tenn., as Speaker of the House, and the motion was seconded by Drs. Peter Irving, New York, and H. B. Everett, Tennessee, and carried.

The Secretary cast the unanimous ballot of the House for Dr. H. H. Shoulders, Nashville, Tenn., and the Vice Speaker declared Dr. Shoulders elected Speaker of the House for the ensuing year.

Election of Vice Speaker of the House of Delegates

The Speaker resumed the chair and announced that the next order of business was the election of a Vice Speaker of the House of Delegates.

Dr. H. L. Snyder, Kansas, nominated Dr. R. W. Fouts, Omaha, for reelection as Vice Speaker, and the nomination was seconded by Drs. Arthur J. Bedell, Section on Ophthalmology; James Q. Graves, Louisiana, and H. B. Everett, Tennessee.

Dr. McLain Rogers, Oklahoma, moved that the nominations be closed and that the Secretary be instructed to cast the ballot of the House for Dr. R. W. Fouts as Vice Speaker. The motion was seconded by Dr. W. E. Kittler, Illinois, and carried. The Secretary cast the unanimous ballot of the House for Dr. R. W. Fouts for Vice Speaker of the House, and the Speaker declared Dr. Fouts so elected for the ensuing year.

Election of Trustees

The Speaker declared the next order of business to be the election of two Trustees, each to serve five years, to succeed Drs. Roger I. Lee, Boston, and Allen H. Bunce, Atlanta, Ga., whose terms expire this year.

Dr. George Blumer, Connecticut, nominated Dr. Roger I. Lee to succeed himself as a Trustee, and the nomination was seconded by Drs. George W. Kosmak, New York; A. A. Walker, Alabama; Deering G. Smith, New Hampshire; Alfred T. Gundry, Maryland; Guy W. Wells, Rhode Island; Samuel P. Mengel, Pennsylvania; William A. Ellingwood, Maine; Walter E. Vest, West Virginia; Warren F. Draper, United States Public Health Service, and A. T. McCormack, Kentucky.

On motion of Dr. George W. Kosmak, New York, seconded by Dr. John Z. Brown Sr., Utah, and carried, the nominations were closed and the Secretary was directed to cast the ballot of the House for Dr. Roger I. Lee.

The Secretary cast the unanimous ballot of the House for Dr. Roger I. Lee, Boston, to succeed himself as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. Lee so elected.

The Speaker asked for nominations for Trustee to succeed Dr. Allen H. Bunce, Atlanta, Ga., who was ineligible, according to the By-Laws, to succeed himself.

Dr. A. T. McCormack, Kentucky, nominated Dr. E. L. Henderson, Louisville, Ky., to succeed Dr. Allen H. Bunce as Trustee of the American Medical Association and the nomination was seconded by Drs. Harvey F. Garrison, Mississippi; George M. Fisher, New York; T. K. Gruber, Michigan; Robert A. Peers, California, and E. H. Cary, Texas.

On motion of Dr. Edward M. Pallette, California, seconded by Dr. Felix J. Underwood, Mississippi, and carried, the nominations were closed and the Secretary was instructed to cast the ballot of the House for Dr. E. L. Henderson as Trustee.

The Secretary cast the unanimous ballot of the House for Dr. E. L. Henderson, Louisville, Ky., to succeed Dr. Allen H. Bunce, Atlanta, Ga., as a member of the Board of Trustees for a term of five years, and the Speaker declared Dr. E. L. Henderson so elected.

Appreciation of Trustee, Dr. Allen H. Bunce

Dr. Charles W. Roberts, Georgia, addressed the House as follows:

Mr. Speaker and Members of the House:

Sir Walter Scott in his "Love of Country" from "The Lay of the Last Minstrel" poignantly laments the unhappy ending of those whose lives are moored in the chilling fog of selfishness. Thus benighted, they sense none of the moving emotions which spring from the deeper reservoirs of the human heart. For such there is no real love of country, no plaudits for their fellows whose days are spent in fervent devotion to our American institutions. With souls so dead their passing, in the words of Scott, is "unwept, unhonored and unsung." But such laments were not spoken of the servants of the American Medical Association. I am moved, therefore, on this occasion to lay a small tribute at the feet of a group whose responsive natures lure them to perpetual battle against the enemies of life's eternal values. In this honored company we find the officers, trustees, councilmen, delegates and committees, yes, the rank and file of the membership of the American Medical Association whose high aims and purposes need no eulogy in this loyal assembly.

For we know that all great lives are not spent on fields of battle, not all great victories staged in the spotlight of public acclaim. Country and section and state and community still have the devoted services of a host of our fellow members who count it their reasonable duty to devote themselves unselfishly to the common good. Is it, then, inappropriate to yield on occasion to the patriotic impulse to applaud or to be considered as outmoded sentiment when a moment is taken to record, in the name of American medicine, a debt of gratitude which none would deny is due such an esteemed company? I hope not.

Moved, Mr. Speaker, by naught but a driving passion for the retention and preservation of our American way of life and the people's medical service, this preferred group of our fellows diligently labor with no thought of reward save a consciousness of duty well performed and a tradition bravely defended.

But may I be more specific. There are men who stand above their comrades because their restless souls yield to no defeat. Such a one is Dr. Allen H. Bunce, many years secretary of the Medical Association of Georgia and editor of its journal, leader and exemplar of the finest traditions of American medicine, loyal defender of its tenets when others were capitulating to the importunities of the ephemeral era. He has just concluded ten years of service on the Board of Trustees. We may be pardoned, I hope, for expressing, as he resumes his place among those who move in the humble places, a laudatory sentiment in your name and particularly in that of the great Southeastern section which he has so well represented. But Dr. Bunce is a young man. He looks forward. Those of us coming from the territory whose medical prerogatives he has so faithfully championed can but express the hope that his exceptional talents may suffer no obscurity because, according to custom, he must terminate his official connection with the Board of Trustees.

Moreover, speaking for myself and as one who has been privileged to live as his neighbor and thus to know of the depth and soundness of the motives which have guided his career, I am bold to voice the conviction that his contributions to the field of medical organization and clinical practice in the past will be complemented by no less fervor as he resumes the responsibilities of a mere Fellow in our beloved organization. United support of every effort directed at the preservation of

a great, free profession seems more than ever the need of the hour. To this end he will be found ready to serve whenever and wherever his colleagues may direct.

At the risk, therefore, of qualifying as a sentimentalist, I embrace the privilege of moving, and Mr. Speaker I do so move, that these comments be spread on the minutes of this House as a small token of appreciation of the spirit of service exemplified by the knights of our profession, particularly by that of the Board of Trustees on which Dr. Bunce has served with such unwavering fidelity. To him and to all who amidst the cheerless atmosphere of distrust and ill becoming complaint have nevertheless held fast to the traditions of our great calling, we pledge in a like spirit our unswerving loyalty. On their shoulders we would lay with ardent appreciation our cherished accolades.

The motion was seconded by Dr. William H. Myers, Georgia, John Q. Myers, North Carolina, Edgar A. Hines, South Carolina, John Z. Brown Sr., Utah, and Felix J. Underwood, Mississippi, and carried.

Presentation of Newly Elected Trustees

The Speaker requested Dr. Roger I. Lee and Dr. E. L. Henderson to present themselves to the chair to be recognized by the House. Dr. Lee asked to be presented from where he stood and Dr. Henderson addressed the House as follows:

Mr. Speaker and Members of the House of Delegates:

I want to thank you for the honor you have bestowed on me, and I appreciate greatly the confidence you have expressed in me. I wish to state that I will serve you to the very best of my ability.

Address of Vice President Alphonse McMahon

Dr. R. Emmet Kane, Missouri, presented Dr. Alphonse McMahon, who addressed the House as follows:

Mr. Chairman, I am actually rendered speechless and I have no notes in my pocket to refer to at this moment to help me through the situation. I don't know what to say to you except that I am very happy at the honor you have bestowed on me and I am particularly delighted at the opportunity to serve the American Medical Association in this capacity and in any other in which it may see fit to place me. I want to thank the American Medical Association again for having come to St. Louis and having given us an opportunity to provide entertainment. We feel that this year the history of the American Medical Association is one of the most momentous of all years. We think that history has been made in St. Louis by the action of this House of Delegates. Thank you again for this honor which you have given me.

Nominations for Standing Committees

Dr. Rock Sleyster, President, submitted the following nominations for standing committees:

Judicial Council: Dr. Edward R. Cunniffe, New York, to succeed himself, for a term ending in 1944; Dr. Holman Taylor, Fort Worth, Texas, to fill the unexpired term ending in 1942 of Dr. John W. Burns, deceased.

Council on Medical Education and Hospitals: Dr. Ray Lyman Wilbur, Stanford University, Calif., to succeed himself, for a term ending in 1946.

Council on Scientific Assembly: Dr. J. Gurney Taylor, Milwaukee, to succeed himself, for a term ending in 1944; Dr. Samuel P. Mengel, Wilkes-Barre, Pa., to fill the unexpired term ending in 1941 of Dr. J. C. Flippin, deceased.

The nominations of Dr. Edward R. Cunniffe and Dr. Holman Taylor for membership on the Judicial Council were confirmed on motions, duly seconded and carried.

The President stated that he was in doubt as to how the adoption of the amendments to the By-Laws at this meeting of the House affected the nomination to the Council on Medical Education and Hospitals at this session and requested a ruling.

After discussion, the Speaker ruled that with the consent of the House the amended By-Laws would take effect in 1940; that the By-Laws as in existence prior to the amendment were in existence at this time, and that the President should proceed with the nomination.

Dr. Samuel J. Kopetzky, New York, moved that the ruling of the Speaker be the sense of the House, and the motion was seconded by Dr. John Q. Myers, North Carolina, and many others, and carried.

The President's nomination of Dr. Ray Lyman Wilbur to succeed himself on the Council on Medical Education and Hospitals was confirmed on motion of Dr. Arthur J. Bedell, Section on Ophthalmology, seconded by Dr. Felix J. Underwood, Mississippi, and carried.

The nominations of Dr. J. Gurney Taylor, Milwaukee, and Dr. Samuel P. Mengel, Wilkes-Barre, Pa., for membership on the Council on Scientific Assembly were confirmed on motions duly seconded and carried.

Election of Affiliate and Associate Fellows

The Secretary presented the following nominations for Affiliate and Associate Fellowship, which, on motions duly seconded and carried, were confirmed by the House:

NOMINATIONS FOR AFFILIATE FELLOWSHIP APPROVED BY THE COUNCIL ON SCIENTIFIC ASSEMBLY

Adams, W. J., Norfolk, Va.
Barck, Carl, St. Louis.
Barnes, J. Steele, Milwaukee.
Blickensderfer, G. M., Denver.
Boisliniere, Louis C., St. Louis.
Breid, Jacob, Spickard, Mo.
Brown, Adelaide, San Francisco.
Campbell, Given, St. Louis.
Charles, Joseph W., St. Louis.
Child, Scott P., West Plains, Mo.
Cook, Emmett F., St. Joseph, Mo.
Croskey, John Welsh, Philadelphia.
Davison, Charles, Chicago.
Gaebler, Arthur, Chicago.
Gaines, S. E., Sparta, Tenn.
Garner, R. L., Milan, Mo.
Gillman, Robert W., Detroit.
Goodwin, Edward J., St. Louis.
Grimes, W. P., Kansas City, Mo.
Hall, D. Walton, Kansas City, Mo.
Harrison, Wallace K., Chicago.
Heusinkveld, Henry J., Fulton, Ill.
Hickok, H. S., Kansas City, Mo.
Hollis, Luther T., Kansas City, Mo.
Hoxie, George H., Kansas City, Mo.
Kauffman, Frank E., Clearwater, Fla.
Kuh, Edwin J., Chicago.
Laughlin, C. E., Evansville, Ind.
Leonard, Ward H., Kansas City, Mo.
Lewis, Bransford, St. Louis.
Lewis, Robert, New York.
Link, J. J., St. Louis.
Mardorf, W. Charles, St. Louis.
Middleton, James, Kansas City, Mo.
Miel, George W., Denver.
Moore, Josiah G., Mexico, Mo.
Murphy, R. Brent, St. Louis.
Myers, John L., Kansas City, Mo.
Neff, Frank C., Kansas City, Mo.
Norberg, George B., Kansas City, Mo.
Perkins, Jay, Stockton Springs, Me.
Phillips, N. W., Clear Lake, Iowa.
Piedalue, Joseph, Lewistown, Mont.
Redmond, Thomas, St. Joseph, Mo.
Rinehart, J. S., Camden, Ark.
Robinson, Ernest F., Kansas City, Mo.
Robinson, G. Wilse, Kansas City, Mo.
Rosenwald, Leon, Kansas City, Mo.
Schwarz, L. E., Chicago.
Scott, William P., Houghton, Mich.
Sherman, Frank M., Boston.
Shumate, David L., Kansas City, Mo.
Smith, Ellsworth S., St. Louis.
Southworth, Thomas S., New York.
Stapp, Fred B., Chattanooga, Tenn.
Taylor, Alfred S., New York.
Tilton, Benjamin T., New York.
Trimble, William K., Kansas City, Mo.
Turner, B. F., Memphis, Tenn.
Veach, Patrick H., Staunton, Ind.
Wilhelm, Francis E., Kansas City, Mo.
Zulick, Thomas C., Easton, Pa.

NOMINATION OF APPLICANT FOR ASSOCIATE FELLOWSHIP FROM FOREIGN COUNTRY ADJACENT TO THE UNITED STATES, APPROVED BY THE JUDICIAL COUNCIL

Boulanger, Joseph, Edmonton, Alberta, Canada.

NOMINATIONS OF AMERICAN MEDICAL MISSIONARIES FOR ASSOCIATE FELLOWSHIP APPROVED BY THE JUDICIAL COUNCIL

Bergsma, Stuart, Taxila, Punjab, North India.
Strain, Richard E., Modesto, Calif.

NOMINATIONS FOR ASSOCIATE FELLOWSHIP APPROVED BY THE SECTIONS INDICATED

PHARMACOLOGY AND THERAPEUTICS

Lehman, Arnold J., Washington, D. C.

PATHOLOGY AND PHYSIOLOGY

Simonsen, Daisy G., Monrovia, Calif.
Visscher, M. B., Minneapolis.

NERVOUS AND MENTAL DISEASES

Slight, David, Chicago.

Address of Dr. L. E. Le Souef

The Secretary presented Dr. L. E. Le Souef, President-Elect of the West Australian Branch of the British Medical Association, who addressed the House as follows: Mr. Speaker, Mr. President, Members of this Great House of Delegates of the American Medical Association: I desire to thank you for the great honor you have conferred on me in permitting me to be present with you this afternoon. Prior to leaving Australia I was present at our board, the Federal Council, when it was dealing with very similar problems to those which have been worrying you at present, that is the question of political control and national health insurance, as we quote it, in Australia. It is interesting to me to find that your problems are similar to ours, and I think in all the great English speaking countries of the world they always will be. To me it is interesting to see you protecting and guarding the highest ethical principles of the profession, and it is of interest to me to know that those principles are international in all their objects.

I have been struck in your country with something on which I should like to compliment you. I have seen a virility of thought and a humility born of wisdom and knowledge which have indeed humbled me in my tour through the States, and I only hope that the supremacy which you have achieved today will be emulated by the rest of the world and that the rest of us will strive to surpass you.

Place of 1942 Annual Session

Dr. Austin A. Hayden, Secretary of the Board of Trustees, presented the following report of the Board:

The Board wishes to report the receipt of invitations from Atlantic City and Philadelphia for the 1942 session of the Association. Both cities have adequate facilities for accommodating a session of the Association.

Dr. Andrew F. McBride, New Jersey, extended an invitation from the Medical Society of New Jersey to meet in Atlantic City, N. J., in 1942.

Dr. Francis F. Borzell, Pennsylvania, extended an invitation from the Philadelphia County Medical Society, the city of Philadelphia, the Medical Society of the State of Pennsylvania, and the physicians of Pennsylvania to meet in Philadelphia in 1942.

The tellers spread the ballot on request of the Speaker, and the Secretary announced that 147 delegates had been reported present and that 130 votes had been cast, of which Atlantic City received 84 and Philadelphia 46. The Speaker declared that the House of Delegates had selected Atlantic City in which to hold the 1942 annual session of the American Medical Association.

NEW BUSINESS

Resolution from the Section on Ophthalmology Requesting Appointment of Special Committee to Study All Phases of Problem of Prevention of Blindness

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, unanimously passed at the executive session of the section, which was adopted on motion of Dr. Bedell, seconded by Dr. Burt R. Shurly, Section on Laryngology, Otology and Rhinology, and carried:

WHEREAS, It is well known that many persons are blind and that a great many have defective sight; and

WHEREAS, An analysis of the records suggests the conclusion that in many cases the sight might have been saved had adequate protective measures been employed; and

WHEREAS, The preservation of human sight is of inestimable value to the individual; and

WHEREAS, A large percentage of the blind are or become public charges; therefore be it

Resolved, That the Section on Ophthalmology petition the House of Delegates to request the Board of Trustees of the American Medical Association to appoint a special committee to study all phases of the problem of prevention of blindness and that a report of its activities be made at the 1940 session of the House of Delegates.

Resolution on Transfer of Health and Medical Activities of Children's Bureau from Department of Labor to United States Public Health Service

Dr. A. T. McCormack asked for and received the unanimous consent of the House for the presentation of the following resolution by Dr. Walter E. Vest, West Virginia:

WHEREAS, The House of Delegates has for years past urged the unification of the health and medical activities of the federal government, except for the medical services of the Army and Navy; and

WHEREAS, These activities are at present widely scattered in various governmental agencies; therefore be it

Resolved, That the House of Delegates of the American Medical Association go on record as favoring: (1) That the health and medical activities of the Children's Bureau be transferred from the Department of Labor and placed with the United States Public Health Service; and (2) That the Division of Industrial Health remain in the United States Public Health Service, where it is now.

Dr. Vest moved the adoption of the resolution. The motion was seconded by Drs. John Z. Brown Sr., Utah, Harvey F. Garrison, Mississippi, and H. B. Everett, Tennessee, and, after discussion, failed to carry. The resolution was, therefore, not adopted.

Resolution on Optometry, from the Section on Ophthalmology

Dr. Arthur J. Bedell, Section on Ophthalmology, presented the following resolution, just received by him from the section, which was laid on the table:

WHEREAS, The problem of optometry is pressing for solution; and

WHEREAS, The previous regulations passed by the House of Delegates are widely ignored and do not command general approval by the members of the section; and

WHEREAS, It is proposed to have a careful study made and the problem presented in such form that a postal vote can be obtained based on real knowledge of the facts; therefore be it

Resolved, That the Section on Ophthalmology of the American Medical Association requests that the regulations of the American Medical Association concerning the optometry problem be suspended for one year pending thorough investigation by a special committee appointed by the chairman of the Section on Ophthalmology; and be it further

Resolved, That the delegate of the section be instructed to present this resolution to the House of Delegates and use his best efforts to have the resolution adopted.

Appointments to Committee on Distinguished Service Awards

The Speaker announced that three vacancies were created on the Committee on Distinguished Service Awards by the expiration of the terms of Drs. J. W. Amesse, Colorado, and J. D. Brook, Michigan, and by the resignation of Dr. E. L. Henderson, Kentucky.

The Speaker appointed Dr. A. A. Walker, Alabama, to succeed Dr. J. W. Amesse, and Dr. John H. O'Shea, Washington, to succeed Dr. J. D. Brook, each for a term of three years expiring in 1942, and Dr. Charles W. Stone, Ohio, for the unexpired term of Dr. E. L. Henderson ending in 1941. Drs. J. F. Hassig, Kansas, and Grant C. Madill, New York, are the other two members of the committee and their terms expire in 1940. The Speaker appointed Dr. Grant C. Madill as chairman of the committee.

Message to Dr. E. J. Goodwin

Dr. A. T. McCormack, Kentucky, asked for and received the unanimous consent of the House to present a motion that the President and Secretary convey to Dr. E. J. Goodwin, St. Louis, who was for many years a member of the House, and who is at present ill, the love and affection of the House and regret at his inability to be present during the session. The motion was seconded by several delegates and carried.

Message of Appreciation

Dr. Arthur J. Bedell, Section on Ophthalmology, moved that the House rise in expression of appreciation of the gracious kindness of their hosts shown toward the members of the American Medical Association since their arrival in St. Louis. The motion was seconded by Dr. George W. Kosmak, New York, and carried unanimously by a rising vote. The Secretary was requested to communicate this action to the proper committee.

The House of Delegates adjourned at 3:50 p. m., on motion of Dr. E. G. Wood, Tennessee, seconded by Dr. George W. Kosmak, New York, and carried.

MINUTES OF THE SECTIONS

SECTION ON PRACTICE OF MEDICINE

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. N. C. Gilbert, Chicago.

Dr. John S. La Due, Minneapolis, read a paper on "The Treatment of Massive Hemorrhage Due to Peptic Ulcer." Discussed by Drs. Andrew B. Rivers, Rochester, Minn.; Kendall A. Elsom, Philadelphia; Horace W. Soper, St. Louis; L. Wallace Frank, Louisville, Ky.; Willard D. Mayer, Detroit; John M. Blackford, Seattle; Manfred Kraemer, Newark, N. J.; Walter L. Palmer, Chicago; S. Kendig Wallace, Baltimore; Gordon H. Ira, Jacksonville, Fla., and John S. La Due, Minneapolis.

Dr. Curtis F. Garvin, Cleveland, read a paper on "Complications Following the Administration of Sulfanilamide." Discussed by Drs. Francis G. Blake, New Haven, Conn.; Edwin G. Bannick, Seattle; B. K. Wiseman, Columbus, Ohio, and Curtis F. Garvin, Cleveland.

Dr. George Dock, Pasadena, Calif., delivered the Frank Billings Lecture, entitled "Historical Notes on Coronary Occlusion: from Heberden to Osler."

Dr. James H. Means, Boston, read a paper on "The Symptomatology of Lymphoma: Its Endless Variety." Discussed by Drs. Ralph A. Kinsella, St. Louis; Arthur W. Allen, Boston, and James H. Means, Boston.

Drs. Louis R. Limarzi and Emil Schleicher, Chicago, presented a paper on "The Reaction of Peripheral Blood and Bone Marrow in Chronic Hemorrhage and in Essential Thrombocytopenic Purpura."

Drs. Charles A. Doan, B. K. Wiseman and Sloan J. Wilson, Columbus, Ohio, presented a paper on "The Differential Diagnosis and Therapeutic Rationale in Thrombocytopenic Purpura."

These two papers were discussed by Drs. Carl V. Moore, St. Louis; W. M. Fowler, Iowa City; Edward P. Flood, the Bronx, New York; Louis R. Limarzi, Chicago, and B. K. Wiseman, Columbus, Ohio.

THURSDAY, MAY 18—MORNING

The following officers were elected: chairman, Dr. William S. McCann, Rochester, N. Y.; vice chairman, Dr. William B. Porter, Richmond, Va.; secretary, Dr. Fred M. Smith, Iowa City; executive committee, Dr. Francis G. Blake, New Haven, Conn., Dr. N. C. Gilbert, Chicago, and Dr. William S. McCann, Rochester, N. Y.; delegate, Dr. James E. Paullin, Atlanta, Ga.; alternate, Dr. Ernest E. Irons, Chicago; members of the American Board of Internal Medicine, Dr. John H. Musser, New Orleans, and Dr. William J. Kerr, San Francisco.

Drs. L. McKendree Eaton and Samuel F. Haines, Rochester, Minn., presented a paper on "Parathyroid Insufficiency with Symmetrical Cerebral Calcifications: Report of Three Cases, in One of Which the Patient was Treated with Dihydrotachysterol." Discussed by Drs. Fuller Albright, Boston; Peter Bassoe, Chicago; Cyril M. MacBryde, St. Louis; Samuel F. Haines, Rochester, Minn., and L. McKendree Eaton, Rochester, Minn.

Dr. N. C. Gilbert, Chicago, read the chairman's address, entitled "Vasomotor Changes in the Coronary Arteries and Their Possible Significance."

Dr. G. E. Hall, Toronto, read a paper on "Coronary Artery Reflexes in Acute Occlusion."

Drs. Geza de Takats and George K. Fenn, Chicago, presented a paper on "The Mechanism of Death in Pulmonary Embolism."

These two papers were discussed by Drs. A. R. Barnes, Rochester, Minn.; Alfred Blalock, Nashville, Tenn.; James H. Means, Boston; George K. Fenn, Chicago; G. E. Hall, Toronto, and Geza de Takats, Chicago.

Drs. F. L. Chamberlain and Paul D. White, Boston, presented a paper on "The Morgagni-Adams-Stokes Syndrome with Special Reference to Prognosis and Treatment." Discussed by Drs. Drew W. Luten, St. Louis; Fred M. Smith, Iowa City; Hugo A. Freund, Detroit; George K. Fenn, Chicago, and F. L. Chamberlain, Boston.

Dr. Edward F. Bland, Boston, read a paper on "The Delayed Appearance of Heart Disease After Rheumatic Fever."

Dr. William D. Stroud, Philadelphia, read a paper on "Fifteen Years' Observation of Children with Rheumatic Heart Disease."

These two papers were discussed by Drs. Helen B. Taussig, Baltimore; T. Duckett Jones, Boston; Edward F. Bland, Boston, and William D. Stroud, Philadelphia.

FRIDAY, MAY 19—MORNING

A joint meeting was held with the Section on Pharmacology and Therapeutics.

Dr. Clarence F. G. Brown, Chicago, and Dr. R. E. Dolkart, Boston, presented a paper on "An Evaluation of Therapy of Peptic Ulcer." Discussed by Drs. Chester M. Jones, Boston; William H. Olmsted, St. Louis; Andrew B. Rivers, Rochester, Minn., and Clarence F. G. Brown, Chicago.

Dr. Elmer L. Sevringhaus, Madison, Wis., read a paper on "Treatment of the Menopause." Discussed by Drs. August A. Werner, St. Louis, and Elmer L. Sevringhaus, Madison, Wis.

Dr. M. Herbert Barker, Chicago, read a paper on "Treatment of Pneumonia." Discussed by Drs. Jesse G. M. Bullowa, New York; Francis G. Blake, New Haven, Conn., and M. Herbert Barker, Chicago.

Dr. Lewis P. Gundry, Baltimore, read a paper on "Bromide Intoxication: Report of Fifteen Cases." Discussed by Drs. C. C. Underwood, Emporia, Kan.; Elmer L. DeGowin, Iowa City, and Lewis P. Gundry, Baltimore.

Dr. H. P. Smith, Iowa City, read a paper on "Clinical and Experimental Studies on Vitamin K."

Drs. Hugh R. Butt, Albert M. Snell and Arnold E. Osterberg, Rochester, Minn., presented a paper on "The Preoperative and Postoperative Use of Vitamin K in Cases of Obstructive Jaundice."

These two papers were discussed by Drs. I. S. Ravdin, Philadelphia; John D. Stewart, Boston; E. A. Doisy, Ph.D., St. Louis; J. D. Greaves, Ph.D., St. Louis; George V. LeRoy, Chicago; H. P. Smith, Iowa City, and Hugh R. Butt, Rochester, Minn.

SECTION ON SURGERY, GENERAL AND ABDOMINAL

WEDNESDAY, MAY 17, 1939—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Henry W. Cave, New York.

Dr. Russell L. Haden, Cleveland, presented to the section through Dr. Fred W. Rankin, Lexington, Ky., a gavel made of wood from the home of Ephraim McDowell, which was accepted for the section by Dr. Frederick A. Coller, Ann Arbor, Mich. A motion was made by Dr. Coller, regularly seconded and carried, that a letter of appreciation be sent to Dr. Haden by the secretary.

Drs. Frederick A. Coller, Henry K. Ransom and Charles Sherrill Rife, Ann Arbor, Mich., presented a paper on "Reactions of the Peritoneum to Trauma and Infection: Further Experimental Studies."

Dr. Bernhard Steinberg, Toledo, Ohio, read a paper on "Stages in Peritonitis Based on the Defense Mechanism in Relation to Treatment."

Dr. George D. Lilly, Miami, Fla., read a paper on "Complications of Appendical Peritonitis."

These three papers were discussed by Drs. Claude F. Dixon, Rochester, Minn.; J. Shelton Horsley, Richmond, Va.; W. Wayne Babcock, Philadelphia; Alton Ochsner, New Orleans; Frederick A. Coller, Ann Arbor, Mich., and Bernhard Steinberg, Toledo, Ohio.

Drs. Walter M. Boothby, Charles W. Mayo and W. Randolph Lovelace II, Rochester, Minn., presented a paper on "One Hundred per Cent Oxygen: Indications for Its Use and Methods of Its Administration to Surgical Patients." Discussed by Drs. Alvan L. Barach, New York; Jacob Fine, Boston, and Walter M. Boothby, Rochester, Minn.

Drs. Loyal Davis and John Martin, Chicago, presented a paper on "Surgical Lesions in the Paratrigeminal Area." Discussed by Drs. Ernest Sachs, St. Louis, and Loyal Davis, Chicago.

Drs. Albert Behrend and Helena E. Riggs, Philadelphia, presented a paper on "Cerebral Complications Following Surgical Operation." Discussed by Drs. Henry K. Beecher, Boston; F. H. Lewy, Philadelphia, and Albert Behrend, Philadelphia.

THURSDAY, MAY 18—AFTERNOON

Drs. Alton Ochsner and Michael E. DeBakey, New Orleans, presented a paper on "Thrombophlebitis: The Etiologic Factor of Vasospasm and the Treatment by Sympathetic Block." Discussed by Drs. S. H. Sedwitz, Youngstown, Ohio; Geza de Takats, Chicago; John R. Paine, Minneapolis, and Alton Ochsner, New Orleans.

Dr. Frederic W. Taylor, Indianapolis, read a paper on "Arteriosclerotic Gangrene: Relation of the Amputation Stump to Morbidity and Mortality."

Dr. Henry H. Faxon, Boston, read a paper on "Major Amputations in Advanced Peripheral Arterial Obliterative Disease."

These two papers were discussed by Drs. Leland S. McKittrick, Boston; Geza de Takats, Chicago, and Henry H. Faxon, Boston.

Dr. Henry W. Cave, New York, read the chairman's address, entitled "Chronic Intractable Ulcerative Colitis: A Surgical Problem."

Dr. John D. Stewart, Boston, read a paper on "Control of the Hemorrhagic Tendency in Obstructive Jaundice by the Use of Vitamin K." Discussed by Drs. H. P. Smith, Iowa City; Hugh R. Butt, Rochester, Minn.; L. Wallace Frank, Louisville, Ky., and John D. Stewart, Boston.

Dr. Conrad J. Baumgartner, Los Angeles, read a paper on "Congenital Lesions of the Neck." Discussed by Drs. Herbert Willy Meyer, New York, and Conrad J. Baumgartner, Los Angeles.

Dr. Manuel Grodinsky, Omaha, read a paper on "Ludwig's Angina, Retropharyngeal Abscess and Other Deep Abscesses of the Head and Neck." Discussed by Drs. Frederick A. Coller, Ann Arbor, Mich.; Louis J. Birsner, St. Louis and Manuel Grodinsky, Omaha.

FRIDAY, MAY 19—AFTERNOON

Drs. Harvey B. Stone and Samuel McLanahan, Baltimore, presented a paper on "Surgical Aspects of Carcinoma of the Large Bowel." Discussed by Drs. James D. Rives, New Orleans; Leland S. McKittrick, Boston; Henry K. Ransom, Ann Arbor, Mich.; Claude F. Dixon, Rochester, Minn.; Frank H. Lahey, Boston, and Harvey B. Stone, Baltimore.

The following officers were elected: chairman, Dr. Thomas M. Joyce, Portland, Ore.; vice chairman, Dr. William Barclay Parsons, New York; secretary, Dr. Arthur W. Allen, Boston; executive committee, Dr. Hugh H. Trout, Roanoke, Va., Dr. Henry W. Cave, New York, and Dr. Thomas M. Joyce, Portland, Ore.; delegate, Dr. Fred W. Rankin, Lexington, Ky.; alternate, Dr. Robert S. Dinsmore, Cleveland; Board of Governors, American College of Surgeons, Dr. Fred W. Bailey, St. Louis; American Board of Anesthesiology, Dr. Ralph M. Tovell, Hartford, Conn.

Drs. I. S. Ravdin and Alfred Stengel Jr., Philadelphia, presented a paper on "Hypoproteinemia in Surgical Patients." Discussed by Drs. Chester M. Jones, Boston; Robert Elman, St. Louis, and I. S. Ravdin, Philadelphia.

Dr. Harold Lincoln Thompson, Los Angeles, read a paper on "The Immediate and Late Results of Surgical Treatment of Acute Perforation of Peptic Ulcer." Discussed by Drs. Dan C. Donald, Birmingham, Ala.; J. William Thompson, St. Louis; Charles Brown Odom, New Orleans, and Harold Lincoln Thompson, Los Angeles.

Dr. Harold L. Foss, Danville, Pa., read a paper on "Pathogenesis of Thyrotoxicosis with Crisis."

Dr. George Crile Jr., Cleveland, read a paper on "Lateral Aberrant Thyroid Tumors."

Dr. Frank H. Lahey, Boston, read a paper on "The Management of True Intrathoracic Goiter."

These three papers were discussed by Drs. Frederick A. Coller, Ann Arbor, Mich.; James H. Means, Boston; James Davidson Rives, New Orleans; Willard Bartlett Jr., St. Louis, and Harold L. Foss, Danville Pa.

SECTION ON OBSTETRICS AND GYNECOLOGY

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Harvey B. Matthews, Brooklyn.

The following papers were read as a symposium on "Lesions of the Vulva":

Dr. Rollo E. McCotter, Ann Arbor, Mich.: "The Structure of the Lower Portion of the Female Genital Tract."

Dr. Emmerich von Haam, Columbus, Ohio: "Venereal and Nonvenereal Granulomas of the Vulva."

Dr. Clair E. Folsome, Ann Arbor, Mich.: "Benign and Malignant Tumors of the Vulva."

Drs. Fred L. Adair and M. Edward Davis, Chicago: "Atrophy of the Vulva."

These four papers were discussed by Drs. Fred J. Taussig, St. Louis; Emil Novak, Baltimore; E. D. Plass, Iowa City; Rita S. Finkler, Newark, N. J.; Rollo E. McCotter, Ann Arbor, Mich., and Fred L. Adair, Chicago.

Dr. Edmund Lissack, Concordia, Mo., read a paper on "Backache During Pregnancy and Its Management." Discussed by Drs. Buford G. Hamilton, Kansas City, Mo.; G. D. Royston, St. Louis, and Joseph B. De Lee, Chicago.

Dr. E. L. King, New Orleans, read a paper on "The Role of Hypothyroidism in the Causation of Abortion, Especially of the 'Missed' Variety." Discussed by Drs. J. C. Litzenberg, Minneapolis; Jesse W. White, Pueblo, Colo., and Fred J. Taussig, St. Louis.

THURSDAY, MAY 18—MORNING

Dr. George W. Kosmak, New York, read a paper on "The Responsibility of the Medical Profession in the Movement for Birth Control." Discussed by Drs. Charles E. Galloway, Evanston, Ill.; Joseph L. Baer, Chicago; Fred L. Taussig, St. Louis; John Zell Gaston, Houston, Texas, and George W. Kosmak, New York.

Dr. Jacob Kotz, Washington, D. C., read a paper on "The Effects of Obstetric Analgesia on the Newborn Infant."

Drs. David C. Kimball, Wyman C. C. Cole and L. E. Daniels, Detroit, presented a paper on "Studies in Neonatal Asphyxia."

These two papers were discussed by Drs. C. O. McCormick, Indianapolis; Franklin F. Snyder, Chicago; Joseph B. De Lee, Chicago; L. Mason Lyons, Pierce City, Mo.; M. S. Lewis, Nashville, Tenn.; Meyer Bodansky, Galveston, Texas; G. D. Royston, St. Louis; Jacob Kotz, Washington, D. C., and Wyman C. C. Cole, Detroit.

Drs. Richard W. TeLinde and J. Donald Woodruff, Baltimore, presented a paper on "Postoperative Care of the Urinary Bladder." Discussed by Drs. George H. Gardner, Chicago, and William T. Kennedy, New York.

Dr. Harvey B. Matthews, Brooklyn, read the chairman's address, entitled "Obstetric Shock: Its Causes, Recognition and Management."

FRIDAY, MAY 19—MORNING

The following officers were elected: chairman, Dr. Ludwig A. Emge, San Francisco; vice chairman, Dr. Buford G. Hamilton, Kansas City, Mo.; secretary, Dr. Norman F. Miller, Ann Arbor, Mich.; delegate, Dr. George Gray Ward, New York; alternate, Dr. Jean Paul Pratt, Detroit; member of the Board of Governors, American College of Surgeons, Dr. Emil Novak, Baltimore.

Drs. Bernard Portis and Harold A. Roth, Chicago, presented a paper on "The Diagnosis and Treatment of Hyperthyrodism Associated with Pregnancy." Discussed by Drs. Robert D. Mussey, Rochester, Minn., and Bernard Portis, Chicago.

Dr. W. O. Johnson, Louisville, Ky., read a paper on "Diagnosis and Treatment of Varicosities of the Broad Ligament." Discussed by Drs. Thomas B. Sellers, New Orleans; Ralph R. Wilson, Kansas City, Mo., and W. O. Johnson, Louisville, Ky.

Dr. Joshua W. Davies, New York, read a paper on "Stress Urinary Incontinence and Its Relation to Cystocele." Discussed by Dr. R. J. Crossen, St. Louis.

Dr. S. Leon Israel, Philadelphia, read a paper on "A Study of Cervical Polyps." Discussed by Drs. Ludwig A. Emge, San Francisco; Harold S. Morgan, Lincoln, Neb.; Emil Novak, Baltimore; Fred L. Adair, Chicago, and S. Leon Israel, Philadelphia.

Dr. Walter T. Dannreuther, New York, read a paper on "The Treatment of Retrodisplacements of the Uterus." Discussed by Drs. Bertha Van Hoosen, Chicago; R. S. Cron, Milwaukee; Louis E. Phaneuf, Boston; Otto St. Clair Krebs, St. Louis; A. C. Hirschfield, Oklahoma City; William H. Vogt, St. Louis; Harvey B. Matthews, Brooklyn, and Walter T. Dannreuther, New York.

SECTION ON OPHTHALMOLOGY

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. S. Judd Beach, Portland, Maine.

Dr. S. Judd Beach, Portland, Maine, read the chairman's address.

Dr. Allen Greenwood, Boston, read a paper on "Thoughts on Office Practice."

Dr. Walter B. Lancaster, Boston, read a paper on "A Simple Method of Plotting, Recording and Interpreting Disturbances of Ocular Motility."

It was recommended that the transactions for the coming year be dedicated to Dr. Allen Greenwood, Boston, and Dr. Walter B. Lancaster, Boston. The recommendation was adopted.

Dr. Sanford R. Gifford, Chicago, read a paper on "The Treatment of Secondary Glaucoma." Discussed by Drs. Edward C. Ellett, Memphis, Tenn.; Theodore L. Terry, Boston; Clifford B. Walker, Los Angeles, and Sanford R. Gifford, Chicago.

Drs. Everett L. Goar and Jacob F. Schultz, Houston, Texas, presented a paper on "Iridencleisis in Glaucoma." Discussed by Drs. Clyde A. Clapp, Baltimore; Thomas D. Allen, Chicago; Allen Greenwood, Boston; John Green, St. Louis; Michael Goldenburg, Chicago; Sanford R. Gifford, Chicago; John Oliver McReynolds, Dallas, Texas, and Jacob F. Schultz, Houston, Texas.

On motion duly seconded and carried, the following resolution was adopted by the section:

WHEREAS, In the latest national public health survey, it has been found that ninety persons in every 100,000 in the United States are blind, and that a vastly greater number have economically defective sight; and

WHEREAS, At a moderate estimate, in not less than one third of those who are blind the sight might have been saved had adequate protective measures been employed; and

WHEREAS, *Not only is the preservation of human sight of inestimable* value to the individual by rendering him capable of meeting the necessities of life, but a large proportion become wards of the nation instead of self-supporting citizens, thereby adding an enormous burden in taxes on those already heavily burdened people; therefore, be it

Resolved, That the Board of Trustees be requested to appoint a committee to investigate the conditions causing these losses of sight and to take such measures as will aid in diminishing the numbers who become unnecessarily blind.

Dr. Algernon B. Reese, New York, read a paper on "The Value of Early Operation in Chronic Primary Glaucoma." Discussed by Drs. Harry S. Gradle, Chicago, and Algernon B. Reese, New York.

Dr. Manual U. Troncoso, New York, read a paper on "Cyclodialysis with Metal Implant in the Treatment of Glaucoma." Discussed by Drs. Otis R. Wolfe, Marshalltown, Iowa, and Manuel U. Troncoso, New York.

THURSDAY, MAY 18—AFTERNOON

Dr. John J. Prendergast, St. Paul, read a paper on "Ocular Leprosy in the United States." Discussed by Drs. Gideon M. Van Poole, Honolulu, Hawaii; Forrest J. Pinkerton, Honolulu, Hawaii; Theodore J. Dimitry, New Orleans, and John J. Prendergast, St. Paul.

Executive Session

The section went into executive session to consider the following recommendation from the Committee on Optics and Visual Physiology:

"That the American Committee on Optics and Visual Physiology recommend to the Section on Ophthalmology of the American Medical Association that all resolutions of the American Medical Association concerning the optometry problem be suspended for one year, pending thorough investigation by a special committee; further,

"That the delegate of the section be instructed to present this resolution to the House of Delegates of the American Medical Association and use his best efforts to have this resolution adopted."

The recommendation was adopted, with fifty-three voting in favor and thirty-eight against.

Scientific Session

Dr. Frederick A. Davis, Madison, Wis., read a paper on "Primary Tumors of the Optic Nerve: A Phenomenon of von Recklinghausen's Disease; a Clinical and Pathologic Study with a Report of Five Cases and a Review of the Literature." Discussed by Drs. Percival Bailey, Chicago; Jesse M. Levitt, Brooklyn; F. Park Lewis, Buffalo; Alan C. Woods, Baltimore and Frederick A. Davis, Madison, Wis.

Dr. Theodore L. Terry, Boston, read a paper on "Malignant Melanoma of Uvea—So-Called Sarcoma: Problems in Diagnosis." Discussed by Drs. Everett C. Moulton, Fort Smith, Ark.; Allen Greenwood, Boston; Charles H. May, New York, and Theodore L. Terry, Boston.

Drs. Alan C. Woods and Earl L. Burky, Baltimore, presented a paper on "Experimental Studies on Ocular Tuberculosis: IV. Studies in the Immune-Allergic Rabbit." Discussed by Drs. Martin Hayward Post, St. Louis, and Albert L. Brown, Cincinnati.

Dr. S. Rodman Irvine, Los Angeles, read a paper on "A Study of Exfoliation of the Lens Capsule, 'Glaucoma Capsularis,' with a Report of Forty Cases." Discussed by Drs. Daniel B. Kirby, New York; Parker Heath, Detroit; Arthur J. Bedell, Albany, N. Y.; Theodore L. Terry, Boston; Harry S. Gradle, Chicago, and S. Rodman Irvine, Los Angeles.

Dr. Milton L. Berliner, New York, read a paper on "Cataract Following Inhalation of Paradichlorobenzene." Discussed by Dr. James E. Lebensohn, Chicago.

Demonstration Session

Dr. Conrad Berens, New York, presented "A Modified Perlia Test for Depth Perception at the Middle Distance," "Visual Acuity Test Applicable to Large Groups of Subjects" and "Large Square Prisms of Thermoplastic Material."

Drs. Theodore L. Terry, Boston, and R. D. Mattis, St. Louis, presented "A Plastic Transilluminator."

FRIDAY, MAY 19—AFTERNOON

Executive Session

Dr. Derrick Vail, Cincinnati, the secretary, read the report of the Committee on Compensation Tables, in which it was stated that its work had not been completed and suggested that it be continued for another year, and that the name of the Committee be changed to "Committee on Visual Economics." The report was accepted.

Dr. Walter B. Lancaster, Boston, read the report of the Committee on Optics and Visual Physiology, which was accepted.

It was moved by Dr. Arthur J. Bedell, Albany, N. Y., seconded by Dr. Lancaster, and carried, that due notice be given through THE JOURNAL in relation to the nonacceptance of the commonly used school testing instruments.

The report of the Committee on the Knapp Testimonial Fund was presented by Dr. Parker Heath, Detroit. The report was accepted.

Dr. Derrick Vail, Cincinnati, reported for the Committee on Awarding the Knapp Medal that no award would be made this year.

The report of the Committee on the American Board of Ophthalmology was read by Dr. Derrick Vail, Cincinnati. The report was accepted.

Dr. Derrick Vail, Cincinnati, read the report of the Committee on National Museum of Ophthalmic Pathology. The report was accepted.

Dr. Arthur J. Bedell, Albany, N. Y., reported as delegate of the section to the House of Delegates. He stated that the resolution adopted by the section on Wednesday morning was unanimously passed by the House; also that the recommendation adopted by the section from the Committee on Optics and Visual Physiology was tabled in the House.

Dr. Derrick Vail, Cincinnati, read the report of the Committee on Museum of Ophthalmic History. The report was accepted.

Dr. Derrick Vail read the report of the Committee on Standardization of Drugs and Instruments. The report was accepted with thanks and the committee discharged.

A vote of thanks was extended the local committee.

A report from the Joint Committee on Orthoptics was read by Dr. Derrick Vail, the secretary.

Dr. William L. Benedict, Rochester, Minn., reported for the Advisory Committee on Student Health Council that the committee had met with the Student Health Committee on three different occasions during the past year, and they had designed a student floor lamp and table-type lamp that will give the standard illumination without glare and with proper spread. The designs have been submitted to manufacturers through the National Society for the Prevention of Blindness. A uniform record card for the recording of examination of students in the Student Health Association has been printed and distributed to all colleges that partake in this organization. In order to make it more uniform, the committee has designed and written specifications for the manufacture of illuminated eye test chart holder with lamp for muscle examinations, which tests were gotten up with the aid of the Electrical Testing Laboratories of New York, submitted to the Committee on Optics and Visual Physiology, and the plan was acceptable to that committee. The report was accepted.

Dr. T. E. Sanders, St. Louis, read the report of the Exhibit Committee of the Section. The report was accepted.

The following officers were elected: chairman, Dr. Harry S. Gradle, Chicago; vice chairman, Dr. Everett L. Goar, Houston, Texas; secretary, Dr. Derrick Vail, Cincinnati; delegate, Dr. Arthur J. Bedell, Albany, N. Y.; alternate, Dr. Lawrence T. Post, St. Louis.

Dr. Sanford R. Gifford, Chicago, was reappointed to the American Committee (Joint) on Optics and Visual Physiology for three years.

Dr. Allen Greenwood, Boston, was appointed to fill a vacancy on the American Board of Ophthalmology, to serve for four years beginning Jan. 1, 1940.

Dr. Jonas S. Friedenwald, Baltimore, was appointed to the Committee on National Museum of Ophthalmic Pathology (Joint).

Dr. Georgiana Dvorak Theobald, Oak Park, Ill., was reelected to fill the vacancy of chairman of the Committee for Scientific Exhibit from the Section. Dr. Derrick Vail, Cincinnati, and Dr. Algernon B. Reese, New York, were appointed as members of the Committee.

Dr. Cassius D. Wescott, Chicago, was appointed to fill a vacancy in the Committee on Museum of Ophthalmic History. Dr. Allen Greenwood, Boston, was elected chairman of the committee.

Dr. Derrick Vail, Cincinnati, was elected to the American Council on Orthoptics, representing the section, to serve for three years; Dr. George P. Guibor, Ottawa, Ill., to serve for two years, and Dr. Harold Gifford Jr., Omaha, to serve for one year.

Dr. William L. Benedict, Rochester, Minn., was reappointed to the advisory committee of the Student Health Association.

A committee of three members was formed, representing the section, to act with similar committees to be appointed from the American Ophthalmological Society of the American Academy of Ophthalmology and Oto-Laryngology, whose function shall be the study of the problem of abstracting ophthalmic literature. To this committee, to be known as the Committee on Ophthalmic Literature (Joint), were appointed Dr. Parker Heath, Detroit, chairman, Dr. Lawrence T. Post, St. Louis, and Dr. Theodore L. Terry, Boston.

Drs. Frederick H. Verhoeff, Boston; Arthur J. Bedell, Albany, N. Y., and Clifford B. Walker, Los Angeles, were elected to constitute the Knapp Medal Award Committee.

Scientific Session

Dr. Lowell S. Selling, Detroit, read a paper on "Examinations of the Eye and Their Significance in Traffic Court Cases." Discussed by Drs. Arthur J. Bedell, Albany, N. Y.; Albert C. Snell, Rochester, N. Y., and Lowell S. Selling, Detroit.

Dr. F. Park Lewis, Buffalo, read a paper on "Ophthalmology's Place in the Prevention of Blindness." Discussed by Drs. Edward V. L. Brown, Chicago; Conrad Berens, New York, and F. Park Lewis, Buffalo.

Dr. Julian Y. Malone, Milwaukee, read a paper on "Progressive Myopia, Keratoconus and Keratoglobus: Their Etiology and Treatment." Discussed by Drs. William L. Benedict, Rochester, Minn.; Meyer Wiener, St. Louis; Theodore L. Terry, Boston, and Julian Y. Malone, Milwaukee.

Drs. Abbott M. Dean, F. W. Dean and Guy R. McCutchan, Council Bluffs, Iowa, presented a paper on "Interstitial Keratitis Caused by Specific Sensitivity." Discussed by Drs. Albert D. Ruedemann, Cleveland, and Abbott M. Dean, Council Bluffs, Iowa.

On motion of Dr. Arthur J. Bedell, Albany, N. Y., duly seconded, a rising vote of thanks was extended the chairman, secretary and other officers of the section.

SECTION ON LARYNGOLOGY, OTOLOGY AND RHINOLOGY

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. H. Marshall Taylor, Jacksonville, Fla.

Dr. Simon L. Ruskin, New York, read a paper on "The Arterial, Venous and Lymphatic Supply of the Nose and the Nervous and Hormonal Factors in Its Control." Discussed by Drs. O. Jason Dixon, Kansas City, Mo., and Louis J. Birsner, St. Louis.

Dr. Roy F. Nelson, Oakland, Calif., read a paper on "Sinus Surgery: Critical Analysis of Diagnosis and Technic in Operations on the Maxillary Sinus." Discussed by Drs. William Mithoefer, Cincinnati; Millard F. Arbuckle, St. Louis, and Roy F. Nelson, Oakland, Calif.

Dr. Ben L. Bryant, Los Angeles, read a paper on "Argyria Resulting from Intranasal Medication." Discussed by Dr. Gordon F. Harkness, Davenport, Iowa.

Dr. Thomas E. Carmody, Denver, read a paper on "Infection of the Mouth and Face." Discussed by Drs. August L. Beck, New Rochelle, N. Y.; Simon L. Ruskin, New York, and Thomas E. Carmody, Denver.

Dr. Gabriel Tucker, Philadelphia, read a paper on "The Management and Surgical Cure of Cancer of the Larynx." Discussed by Drs. Frederick A. Figi, Rochester, Minn.; LeRoy A. Schall, Boston; Joseph C. Beck, Chicago, and Gabriel Tucker, Philadelphia.

Dr. Austin A. Hayden, Chicago, showed slides and spoke briefly on Audiogram Standardization.

THURSDAY, MAY 18—MORNING

Executive Session

The following officers were elected: chairman, Dr. Arthur W. Proetz, St. Louis; vice chairman, Dr. F. T. Hill, Waterville, Maine; secretary, Dr. LeRoy A. Schall, Boston; executive com-

mittee, Gordon B. New, Rochester, Minn., H. Marshall Taylor, Jacksonville, Fla., and Arthur W. Proetz, St. Louis; delegate, Bert R. Shurly, Detroit; alternate, Gordon F. Harkness, Davenport, Iowa.

A letter was read regarding the tentative draft of school health policies. Drs. Bert R. Shurly, Detroit, George E. Shambaugh Jr., Chicago, and H. B. Searcy, Tuscaloosa, Ala., were appointed a committee to consider the draft.

Dr. John J. Shea, Memphis, Tenn., reported for the American Board of Otolaryngology as follows:

"The American Board of Otolaryngology held its thirty-seventh examination at the St. Louis University on May 11, 12 and 13. One hundred and eight candidates were examined, of whom eighty-four were given certificates, bringing the total to 2,889 certified otolaryngologists.

"For the information of many of the section, the board is composed of two representatives from each of the following: American Otological Society, American Laryngological Society, American Laryngological, Rhinological and Otological Society, American Academy of Ophthalmology and Otolaryngology, and the American Medical Association. This board in turn elects as associate members sufficient help for each examination.

"The minimum requirements for taking the board are one year rotating internship, one year basic training in otolaryngology and one year special internship on a certified otolaryngological service."

The report was accepted.

Scientific Session

Dr. H. Marshall Taylor, Jacksonville, Fla., read the chairman's address, entitled "Otitis and Sinusitis in the Swimmer."

Dr. Daniel S. Cunning, New York, read a paper on "Treatment of Otitic Meningitis: Surgery Plus Sulfanilamide."

Dr. John M. Converse, New York, read a paper on "Recurrence of Otitic Infections Due to Beta-Hemolytic Streptococci Following Inadequate Sulfanilamide Therapy."

These two papers were discussed by Drs. Wells P. Eagleton, Newark, N. J.; Bernard J. McMahon, St. Louis; Anchise A. Cirillo, New York, and P. Pierre Viole, Los Angeles.

Dr. V. H. Kazanjian, Boston, read a paper on "Reconstruction Following Radical Operation for Osteomyelitis of the Frontal Bone." Discussed by Drs. Harris P. Mosher, Boston, and Vilray P. Blair, St. Louis.

Dr. George E. Shambaugh Jr., Chicago, read a paper on "Diplacusis: A Localizing Symptom for Disease of the Organ of Corti; Theoretical Considerations, Clinical Observations and Practical Application." Discussed by Drs. Arthur W. Proetz, St. Louis, and George M. Coates, Philadelphia.

Dr. Edmund P. Fowler Jr., New York, read a paper on "Abnormal Movements Following Injury to the Facial Nerve." Discussed by Drs. Joseph A. Sullivan, Toronto, Canada; Ernest Sachs, St. Louis, and Edmund P. Fowler Jr., New York.

FRIDAY, MAY 19—MORNING

A joint meeting was held with the Section on Pediatrics.

Dr. John J. Shea, Memphis, Tenn., read a paper on "Rational Treatment of Sinusitis in Children." Discussed by Drs. Lee Wallace Dean Jr., St. Louis; Harris Hosen, Port Arthur, Texas; Clifford Sweet, Oakland, Calif.; T. E. Walsh, Chicago; George Piness, Los Angeles, and John J. Shea, Memphis, Tenn.

Dr. Horace J. Williams, Philadelphia, read a paper on "The Diagnosis and Treatment of Otitis Media in Children." Discussed by Drs. Dean M. Lierle, Iowa City; Borden S. Veeder, St. Louis; Charles Hendee Smith, New York; Clifford Sweet, Oakland, Calif.; Eugene Lee Myers, St. Louis, and Horace J. Williams, Philadelphia.

Drs. T. Duckett Jones and John R. Mote, Boston, presented a paper on "The Clinical Importance of Respiratory Infections in Rheumatic Fever." Discussed by Drs. William P. Wherry, Omaha; William D. Stroud, Philadelphia, and T. Duckett Jones, Boston.

Drs. George Piness and Hyman Miller, Los Angeles, presented a paper on "Upper Respiratory Allergy in Infancy and Childhood." Discussed by Drs. Francis M. Pottenger Jr., Monrovia, Calif., and George Piness, Los Angeles.

SECTION ON PEDIATRICS

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2:10 by the chairman, Dr. Edward Clay Mitchell, Memphis, Tenn.

Dr. M. Hines Roberts, Atlanta, Ga., read a paper on "A Study of Cerebral Hemorrhage in the Newborn." Discussed by Drs. Ralph M. Tyson, Philadelphia; Hugo Ehrenfest, St. Louis; Julius H. Hess, Chicago, and M. Hines Roberts, Atlanta, Ga.

Dr. Heyworth N. Sanford, Chicago, read a paper on "The Effect of Various Complementary Feedings on the Gain in Weight and Stimulation of Breast Milk During the Newborn Period." Discussed by Drs. Clifford G. Grulee, Evanston, Ill.; William J. Orr, Buffalo, and Heyworth N. Sanford, Chicago.

Dr. Edward Clay Mitchell, Memphis, Tenn., read the chairman's address, entitled "Child Health in National Defense."

Dr. Harry H. Donnally, Washington, read a paper on "Smallpox Vaccination of Infants: Revaccinations After Two to Three Years in Children Primarily Vaccinated with Culture Virus (Rivers), Compared with Those Primarily Vaccinated with Calf Lymph Virus." Discussed by Dr. Charles Armstrong, Washington, D. C.

Dr. M. G. Peterman, Milwaukee, read a paper on "Convulsions in Infancy and Childhood: A Report of One Thousand Cases." Discussed by Drs. Henry F. Helmholz, Rochester, Minn.; H. R. Cooder, Los Angeles; Clifford Sweet, Oakland, Calif., and M. G. Peterman, Milwaukee.

Dr. Warren W. Quillian, Coral Gables, Fla., read a paper on "Respiratory Infections: Types and Clinical Course as Observed in Florida Pediatric Practice." Discussed by Drs. Robert A. Strong, New Orleans, and Oscar Reiss, Los Angeles.

THURSDAY, MAY 18—AFTERNOON

Dr. Ralph M. Tyson, Philadelphia, chairman of the executive committee, presented the following resolutions, which, on motion regularly made and seconded, it was voted to approve:

WHEREAS, The American Medical Association is devoted to the best interests of all the physicians of the United States; and

WHEREAS, The Section on Pediatrics of the American Medical Association is a loyal constituent part of that Association, with interests which are identical with those of all other groups making up the American Medical Association; therefore, be it

Resolved, That we, the executive committee of the Section on Pediatrics, representing that section, do hereby indicate our wholehearted and unswerving loyalty to the American Medical Association; be it further

Resolved, That the Section on Pediatrics, through its executive committee, will endeavor to gather from the principal pediatric groups and all interested individuals engaged in the practice of pediatrics their ideas and suggestions for the advancement of the welfare of American medicine within the field of child study.

In order that the representative of the Section on Pediatrics in the House of Delegates may present such suggestions for the consideration and action of the said House of the American Medical Association.

RALPH M. TYSON, Chairman.
CLIFFORD SWEET.
EDWARD CLAY MITCHELL.

Resolved, That the Section on Pediatrics of the American Medical Association commend the American Legion for its interest in child welfare and offer its assistance for carrying out these plans where they have been prepared under pediatric leadership.

Dr. Ralph M. Tyson announced that Dr. Edward Clay Mitchell had been designated as the section representative to cooperate with the Child Health Director of the American Legion.

Speaking on behalf of the secretary of the Abraham Jacobi Memorial Fund, who was absent, Dr. Ralph M. Tyson reported that at the present time there is $7,502.62 in the treasury, and that very little money had been spent during the past year.

The executive committee recommended the appointment of Dr. Arthur H. Parmelee of Chicago and Dr. Wyman C. C. Cole of Detroit to represent the Section on Pediatrics as members of a committee from various organizations engaged in a

study on the Problems of the Fetus and the Newborn Infant. On motion regularly made, seconded and carried, the section approved the appointments as recommended.

The following officers were elected: chairman, Dr. Albert D. Kaiser, Rochester, N. Y.; vice chairman, Dr. Philip M. Stimson, New York; secretary, Dr. Hugh L. Dwyer, Kansas City, Mo.; executive committee, Dr. Clifford Sweet, Oakland, Calif., Dr. Edward Clay Mitchell, Memphis, Tenn., and Dr. Albert D. Kaiser, Rochester, N. Y.; delegate, Dr. William Weston, Columbia, S. C.; alternate, Dr. A. Graeme Mitchell, Cincinnati; representative to the Board of Pediatrics, Dr. Horton R. Casparis, Nashville, Tenn.; secretary and treasurer of the Abraham Jacobi Memorial Fund, Dr. Hugh L. Dwyer, Kansas City, Mo.

Dr. Oscar Reiss, Los Angeles, chairman of the resolutions committee, presented the report of that committee, as follows:

In behalf of the officers and members of the Section on Pediatrics of the American Medical Association here assembled in St. Louis for their ninetieth annual session, it is our privilege to offer to Dr. Jean V. Cooke, and the rest of the local contingent, our heartfelt appreciation of the magnificent hospitality they have extended to us.

We will all carry away a memory of the splendid scientific program and exhibits, and of the genial reception extended us by perfect hosts.

OSCAR REISS.
LEE FORREST HILL.
WILLIAM ORR.

Dr. Oscar Reiss moved that a copy of these resolutions be spread on the minutes of the section; regularly seconded and carried.

Dr. Henry F. Helmholz, Rochester, Minn., announced that the International Congress on Pediatrics will hold its meeting in Boston, Sept. 3, 4 and 5, 1940, and urged those who had not been solicited, and had exhibits of interest, to get in touch with Dr. Tom Mitchell. Dr. Helmholz extended thanks to the Abraham Jacobi Fund and, through it, to the section, for their generous contribution to meet the expenses of the congress.

Dr. Charles Gilmore Kerley, New York, read a paper on "Varying Manifestations of Thyroid Gland Aberrancies in Infants, Children and Adolescents." Discussed by Dr. Theodore T. Zuck, Cleveland, and Dr. Charles Gilmore Kerley, New York.

A panel discussion on the topic of "Management of Pneumonia in Infancy and Childhood" was conducted under the leadership of Dr. Charles Hendee Smith, New York, assisted by Drs. Alexis F. Hartmann, St. Louis; A. V. Stoesser, Minneapolis; Rosa Lee Nemir, New York, and Benjamin W. Carey Jr., Detroit. The subjects discussed were "Importance of Differentiating Pneumococcic (Lobar) Pneumonia and Bronchopneumonia," "Typing and Its Significance" and "Treatment: Sulfapyridine; Future of Serum; General."

FRIDAY, MAY 19—MORNING

A joint meeting was held with the Section on Laryngology, Otology and Rhinology. The proceedings are reported in the minutes of that section.

SECTION ON PHARMACOLOGY AND THERAPEUTICS

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Erwin E. Nelson, New Orleans.

Dr. P. C. Jeans, Iowa City, read a paper on "Treatment with Preparations Containing Vitamins A and D." Discussed by Drs. Alexis F. Hartmann, St. Louis, and P. C. Jeans, Iowa City.

Dr. Irving S. Wright, New York, read a paper on "Treatment with Vitamin C." Discussed by Drs. S. B. Wortis, New York, and Irving S. Wright, New York.

Drs. Willard O. Thompson and Norris J. Heckel, Chicago, presented a paper on "Treatment with Male Sex Hormones." Discussed by Dr. Elmer L. Sevringhaus, Madison, Wis.; Prof. Ernst Laqueur, Amsterdam, Holland, and Dr. Willard O. Thompson, Chicago.

Dr. H. L. Smith, Rochester, Minn., read a paper on "Treatment of Auricular Fibrillation." Discussed by Drs. Roy W. Scott, Cleveland; Frank J. Hirschboeck, Duluth, Minn.; Morris Margolin, Omaha; S. A. Weisman, Minneapolis, and H. L. Smith, Rochester, Minn.

Dr. I. J. Brightman, Brooklyn, read a paper on "Treatment of Edema by Rectal Administration of Diuretics." Discussed by Dr. Harold J. Stewart, New York.

Drs. Herbert K. Ensworth and Norman H. Plummer, New York, presented a paper on "Treatment of Pneumonia with Sulfapyridine." Discussed by Drs. Russell L. Cecil, New York; H. F. Flippin, Philadelphia; F. Janney Smith, Detroit; Lawrence D. Thompson, St. Louis; Jesse G. M. Bullowa, New York; Wheelan D. Sutliff, New York, and Herbert K. Ensworth, New York.

THURSDAY, MAY 18—AFTERNOON

The following officers were elected: chairman, Dr. Irving S. Wright, New York; vice chairman, Dr. C. M. M. Gruber, Philadelphia; secretary, Dr. E. V. Allen, Rochester, Minn.; delegate, Dr. Russell L. Haden, Cleveland; alternate, Dr. George R. Herrmann, Galveston, Texas; executive committee: Drs. Russell L. Haden, Cleveland, Erwin E. Nelson, New Orleans, and Irving S. Wright, New York.

Dr. Erwin E. Nelson, New Orleans, read the chairman's address, entitled "Variability in Response to Drugs."

Drs. William J. Kerr and P. A. Gliebe, San Francisco, Mayo H. Soley, San Mateo, Calif., and Nathan W. Shock, Berkeley, Calif., presented a paper on "Treatment of the Anxiety States with Special Attention to Certain Physiologic Manifestations." Discussed by Drs. Edward G. Billings, Denver; Fred M. Smith, Iowa City; Walter Freeman, Washington, D. C., and William J. Kerr, San Francisco.

Drs. Fuller Albright, Richard Chute and Hirsh W. Sulkowitch, Boston, presented a paper on "Nonsurgical Aspects of the Kidney Stone Problem." Discussed by Dr. Charles C. Higgins, Cleveland.

Dr. Louis N. Katz, Chicago, read a paper on "The Action of Drugs on the Caliber of the Coronary Vessels." Discussed by Drs. Fred M. Smith, Iowa City; George V. LeRoy, Chicago; George K. Fenn, Chicago; Erwin E. Nelson, New Orleans, and Louis N. Katz, Chicago.

Drs. J. B. Collip, A. H. Neufeld and O. F. Denstedt, Montreal, presented a paper on "The Effects of Pituitary Extracts on Metabolism." Discussed by Drs. Elmer L. Sevringhaus, Madison, Wis., and O. F. Denstedt, Montreal.

Dr. Lester B. Dragstedt, Chicago, read a paper on "The Present Status of Lipocaic." Discussed by Dr. David H. Rosenberg, Chicago.

FRIDAY, MAY 19—MORNING

A joint meeting was held with the Section on Practice of Medicine. The proceedings are reported in the minutes of that section.

SECTION ON PATHOLOGY AND PHYSIOLOGY

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9:05 by the vice chairman, Dr. F. W. Hartman, Detroit.

Dr. M. B. Visscher, Minneapolis, read the chairman's address, entitled "The Restriction of the Coronary Flow as a Factor in Heart Failure." Discussed by Drs. Thomas K. Lewis, Birmingham, Ala., and M. B. Visscher, Minneapolis.

Dr. J. P. Simonds, Chicago, read a paper on "Experimental Studies on the Pathogenesis of Nephritis." Discussed by Drs. Mary B. Baughman, Richmond, Va.; George Milles, Chicago; R. H. Rigdon, Nashville, Tenn., and J. P. Simonds, Chicago.

Dr. Irvine H. Page, Indianapolis, read a paper on "The Production of Persistent Arterial Hypertension by Cellophane Perinephritis." Discussed by Drs. Alvin G. Foord, Pasadena, Calif., and Irvine H. Page, Indianapolis.

Drs. Lawrence W. Smith and Temple S. Fay, Philadelphia, presented a paper on "Temperature Factor in Cancer and

Embryonal Cell Growth." Discussed by Drs. Temple S. Fay, Philadelphia; Israel Davidsohn, Chicago; Mary B. Baughman, Richmond, Va.; F. W. Hartman, Detroit, and Lawrence W. Smith, Philadelphia.

Drs. Samuel H. Geist, Udall J. Salmon and Joseph A. Gaines, New York, presented a paper on "Biologic Effects of Androgens in the Human Female." Discussed by Prof. Ernst Laqueur, Amsterdam, Holland, and Drs. Harold S. Connamacher, Maplewood, N. J., and Udall J. Salmon, New York.

Dr. Frank W. Hartman, Detroit, read a paper on "The Correlation of the Pathologic Lesions and the Anoxia Resulting from Alcohol." Discussed by Drs. M. B. Visscher, Minneapolis; Charles L. Fox Jr., Boston, and Frank W. Hartman, Detroit.

Drs. H. J. Corper, Maurice L. Cohn and A. P. Damerow, Denver, presented a paper on "Relations Between Specific Immunity, Allergy and Anaphylaxis in Tuberculosis." Discussed by Drs. Emil Bogen, Olive View, Calif.; Camille Kereszturi, New York, and H. J. Corper, Denver.

A nominating committee was appointed, consisting of Drs. George Milles, Chicago, chairman; Joseph T. King, Minneapolis, and J. P. Simonds, Chicago.

THURSDAY MAY 18—MORNING

The following officers were elected: chairman, Dr. Frank W. Hartman, Detroit; vice chairman, Dr. Carl J. Wiggers, Cleveland; secretary, Dr. J. J. Moore, Chicago; delegate, Dr. L. W. Larson, Bismarck, N. D.; alternate, Dr. J. J. Moore, Chicago; executive committee, Dr. Roy R. Kracke, Emory University, Ga., Dr. M. B. Visscher, Minneapolis, and Dr. Frank W. Hartman, Detroit.

The following papers were read as a symposium on "Sulfanilamide":

Dr. Sanford M. Rosenthal, Washington, D. C.; "Experimental Chemotherapy with Sulfanilamide and Related Compounds." Discussed by Dr. Charles L. Fox Jr., Boston.

Dr. Joseph T. King, Minneapolis: "Tissue Culture Studies on the Bacteriostatic and Antitoxic Action of Sulfanilamide." Discussed by Dr. Charles L. Fox Jr., Boston.

Drs. Jesse G. M. Bullowa, New York; Edwin E. Osgood, Portland, Ore., and Samuel C. Bukantz, New York: "Effect of Sulfapyridine Alone and with Serum and in Serum of Treated Pneumonia Patients on Pneumococcus Infected Marrow Changes."

These three papers were discussed by Drs. Sanford M. Rosenthal, Washington, D. C.; Joseph T. King, Minneapolis; L. E. Shinn, Ph.D., Pittsburgh, and I. S. Ravdin, Philadelphia.

FRIDAY MAY 19—MORNING

A joint meeting was held with the Section on Nervous and Mental Diseases.

Dr. L. S. King, Princeton, N. J., read a paper on "The Neurotropic Viruses." Discussed by Drs. Robert G. Green, Minneapolis; Richard B. Richter, Chicago, and L. S. King, Princeton, N. J.

The following papers were presented as a symposium on "Vitamin Deficiency and Related Neural Disorders":

Dr. George R. Cowgill, New Haven, Conn.: "Vitamin Deficiencies and the Nervous System: A Consideration of the Contribution of Animal Experimentation."

Dr. F. H. Lewy, Philadelphia: "The Physiologic Action of the Vitamin B Complex."

Dr. Harry M. Zimmerman, New Haven, Conn.: "The Neuropathology of Vitamin B Deficiency."

Drs. Charles D. Aring, Tom D. Spies and J. P. Evans, Cincinnati: "Clinical Aspects of Vitamin B Deficiencies."

These four papers were discussed by Drs. Arthur Weil, Chicago; Hans H. Reese, Madison, Wis.; J. M. Nielsen, Los Angeles; Leo Alexander, Boston; George R. Cowgill, New Haven, Conn.; F. H. Lewy, Philadelphia; Harry M. Zimmerman, New Haven, Conn.; Richard M. Brickner, New York, and Charles D. Aring, Cincinnati.

SECTION ON NERVOUS AND MENTAL DISEASES

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Francis C. Grant, Philadelphia.

Drs. Ann S. Minot, Katherine Dodd and S. S. Riven, Nashville, Tenn., presented a paper on "The Use of Guanidine Compounds in the Treatment of Myasthenia Gravis."

Drs. Henry R. Viets and Robert S. Schwab, Boston, presented a paper on "Myasthenia Gravis."

These two papers were discussed by Drs. J. C. McKinley, Minneapolis; S. S. Riven, Nashville, Tenn.; Ann S. Minot, Nashville, Tenn., and Henry R. Viets, Boston.

Dr. Francis C. Grant, Philadelphia, read the chairman's address, entitled "The Surgical Treatment of Pituitary Adenomas."

Dr. M. C. Sosman, Boston, read a paper on "Irradiation in the Treatment of Pituitary Adenomas." Discussed by Drs. George W. Chamberlin, Philadelphia; Ernest Sachs, St. Louis, and M. C. Sosman, Boston.

Dr. Madelaine R. Brown, Boston, read a paper on "The Role of Potassium Chloride in the Treatment of Ménière's Syndrome."

Drs. A. W. Adson and M. N. Walsh, Rochester, Minn., presented a paper on "Ménière's Disease: Medical and Surgical Treatment."

These two papers were discussed by Drs. F. D. Lathrop, Ann Arbor, Mich.; John H. Talbott, Boston; M. N. Walsh, Rochester, Minn., and A. W. Adson, Rochester, Minn.

THURSDAY, MAY 18—AFTERNOON

The following officers were elected: chairman, Paul C. Bucy, Chicago; vice chairman, John F. Fulton, New Haven, Conn.; secretary, Johannes M. Nielsen, Los Angeles; executive committee: Samuel D. Ingham, Los Angeles, Francis C. Grant, Philadelphia, and Paul C. Bucy, Chicago; delegate, Henry R. Viets, Boston; alternate, R. P. Mackay, Chicago; representative to Scientific Exhibit, F. P. Moersch, Rochester, Minn.; representative on American Board of Psychiatry and Neurology, Hans H. Reese, Madison, Wis.; representative on proposed American Board of Neurosurgery, Paul C. Bucy, Chicago.

Dr. Walter Freeman, Washington, D. C., gave a report from the American Board of Psychiatry and Neurology, which was accepted.

A vote of thanks was given to Dr. Tom B. Throckmorton, Des Moines, Iowa, delegate to the House, and to Dr. Paul C. Bucy, Chicago, secretary.

Dr. Walter F. Schaller, San Francisco, read a paper on "The Post-Traumatic Psychoneurotic State and Traumatic Encephalopathy." Discussed by Drs. George W. Hall, Chicago; Sidney I. Schwab, St. Louis; Harry E. Mock, Chicago; R. P. Mackay, Chicago; Leopold Brahdy, New York, and Walter F. Schaller, San Francisco.

Drs. Stanley Cobb and M. E. Cohen, Boston, presented a paper on "The Differential Diagnosis of Anxiety Neurosis." Discussed by Drs. David Slight, Chicago; George W. Hall, Chicago; Walter F. Schaller, San Francisco, and M. E. Cohen, Boston.

Drs. H. T. Carmichael and J. H. Massermann, Chicago, presented a paper on "Results of Treatment in a Psychiatric Outpatient Department." Discussed by Drs. Lloyd H. Ziegler, Wauwatosa, Wis.; William Nelson, St. Louis; Walter Freeman, Washington, D. C.; U. G. Darling, Chicago, and H. T. Carmichael.

Dr. Tom B. Throckmorton, Des Moines, Iowa, delegate to the House, made a report on the session of the House of Delegates, which was accepted.

Dr. Joseph H. Globus, New York, read a paper on "Probable Topography of the Sleep-Regulating Center." Discussed by Drs. Percival Bailey, Chicago; John F. Fulton, New Haven, Conn., and Joseph H. Globus, New York.

Dr. J. M. Nielsen, Los Angeles, read a paper on "Delayed Paralysis of Nerves from Indirect Trauma." Discussed by Drs. L. J. Pollock, Chicago; R. B. Raney, Los Angeles; Percival Bailey, Chicago, and J. M. Nielsen, Los Angeles.

FRIDAY, MAY 19—MORNING

A joint meeting was held with the Section on Pathology and Physiology. The proceedings are reported in the minutes of that section.

SECTION ON DERMATOLOGY AND SYPHILOLOGY

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2:05 by the chairman, Dr. Bedford Shelmire, Dallas, Texas.

Dr. Bedford Shelmire read the chairman's address, "Weeds Causing Contact Eczema."

Drs. James W. Jordon and Earl D. Osborne, Buffalo, presented a paper on "Contact Dermatitis from Opium Derivatives with Special Reference to Occupational Aspects." Discussed by Drs. M. B. Sulzburger, New York; Bedford Shelmire, Dallas, Texas, and James W. Jordon, Buffalo.

Dr. Francis W. Lynch, St. Paul, read a paper on "A Clinical Study of Acne in University Students." Discussed by Drs. Joseph Gardner Hopkins, New York; R. L. Sutton Jr., Kansas City, Mo.; J. D. Farris, Richmond, Ky., and Francis W. Lynch, St. Paul.

Dr. Merlin T.-R. Maynard, San Jose, Calif., read a paper on "Vitamin Therapy in Dermatology, With Particular Reference to Vitamin D Effects in Acne and Diseases of Altered Calcium Usage." Discussed by Drs. Arthur G. Schoch, Dallas, Texas; Joseph Grindon Sr., St. Louis; Harry M. Robinson, Baltimore; C. J. Lunsford, Oakland, Calif.; M. B. Sulzberger, New York; R. L. Sutton Jr., Kansas City, Mo., and Merlin T.-R. Maynard, San Jose, Calif.

Drs. George M. MacKee and Anthony C. Cipollaro, New York, presented a paper on "Roentgen Dosages in Dermatology Expressed in International Roentgens." Discussed by Drs. Harry R. Foerster, Milwaukee; George C. Andrews, New York; C. Guy Lane, Boston, and Anthony C. Cipollaro, New York.

Drs. W. F. Spiller and W. B. Sharp, Galveston, Texas, presented a paper on "Gentian Violet Treatment of Scalp Ringworms." Discussed by Drs. Leslie M. Smith, El Paso, Texas, and W. F. Spiller, Galveston, Texas.

Drs. Elmore B. Tauber and Leon Goldman, Cincinnati, presented a paper on "Hypertherm Treatment in Skin Diseases." Discussed by Drs. Paul A. O'Leary, Rochester, Minn.; Julian E. Benjamin, Cincinnati, and Elmore B. Tauber, Cincinnati.

Dr. George W. Binkley, Cleveland, read a paper on "Dermatofibrosarcoma Protuberans, with a Report of Six Cases." Discussed by Drs. John H. Lamb, Oklahoma City; Hamilton Montgomery, Rochester, Minn.; Fred D. Wiedman, Philadelphia, and George W. Binkley, Cleveland.

THURSDAY, MAY 18—AFTERNOON

Dr. Hamilton Montgomery, Rochester, Minn., chairman of the Committee on Scientific Exhibit, presented the report of the committee as follows:

Following Dr. O'Leary's suggestion regarding the use of colored motion pictures, it was decided to have a joint motion picture exhibit and various members of the section were asked if they cared to contribute to such an exhibit. Different subjects were chosen by or assigned to the various individuals. This is the first time that the section has tried such an exhibit. Hence it should be looked on as a preliminary effort. Some of the contributors found it difficult to get suitable subjects who were willing to have motion pictures taken of their lesions. The technical difficulties of the use of colored film in dermatology can best be worked out through experience. We hope that a start has been made in the right direction and that the section will feel it worth while continuing with a series of motion pictures next year. Any one interested in participating in a motion picture exhibit is asked to communicate with me at once, as experience shows that much time is necessary in order to work up a given subject or dermatosis properly.

If we keep up this motion picture exhibit next year, plans can be worked out and we shall take other subjects than we took this year. I wish any one would get in touch with me or the representatives from the section so that we can get started on it right away. You think it is easy to pick up a lot of patients with psoriasis or acne, even, then when you try to find them, they don't come in for a couple of months or more.

I wish to express my deepest appreciation to those who cooperated in the motion picture exhibit. In regard to the various exhibits in the section, we were, as usual, unable to accept all the applications that were received because of lack of space. Dr. Clark Finnerud, former chairman, was of great assistance to me in this phase of the work, as was also Dr. Hull.

Our bank account, as a result of the usual donation from the American Medical Association of $25 a year, remains $92.85, as compared to $88.75, as turned over to me by Dr. Finnerud last year.

The chairman appointed Drs. Everett S. Lain, Oklahoma City; Howard King, Nashville, Tenn., and A. H. Lancaster, Knoxville, Tenn., a committee to audit the books of the Committee on Scientific Exhibit.

Dr. Elmore B. Tauber, Cincinnati, reported on the International Dermatological Congress as follows:

As all of you know, the International Dermatological Congress is to meet in New York in 1940 in September. Preliminary to this meeting to make it a success from the scientific point of view, from the social point of view, unfortunately, money is necessary. You all know that Dr. Ormsby is general chairman; Dr. O'Leary is secretary general, and I am chairman of the finance committee.

We decided to have a voluntary assessment of the dermatologists of America. We wanted to make this congress a great success from every point of view from all that has gone before and, if possible, to make it even a greater one than any of the preceding ones. To do this requires a certain amount of funds. This voluntary assessment was suggested of $15 per man practicing dermatology exclusively. We have had a good deal of trouble getting this money together, but it is beginning to take better shape. So this is just another plea, but it is an urgent plea. We really need this. We want to quiet any misapprehensions that may have existed. There is no subsidizing of any man at all. The only way we shall give them anything possibly will be some social function such as a banquet or smoker or something of the sort.

We have a budget prepared of what is necessary. This budget I am going to pass around so each of you can see it. It is taken up with employees, publicity contract, communications, printing, exhibits, rental for meeting places, entertainment and possible contingencies. So we really must have this nucleus so we can start the work. Dr. O'Leary will tell you later on what has been done in both a scientific way and in the way of clearing this up. We are going to have probably anywhere from thirty to thirty-five countries represented, and in these times we certainly want to have a scientific amity, because these are troubled times and we want to show what we can do.

I am not only going to ask to pass copies of the budget around, but I have some cards which will allow you, if you haven't already done so, to put your name down for the amount that you wish to contribute. The minimum we have fixed at $15, but the sky is the limit. If you will sign these and give them to Dr. Lehmann, he will turn them over to me later on."

Dr. Lain reported that the auditing committee found the books and accounts well kept and correct.

On motion by Dr. Paul A. O'Leary, Rochester, Minn., seconded by Dr. James Herbert Mitchell, it was voted to accept the report of the Auditing committee.

Dr. C. Guy Lane, Boston, presented the following report of the American Board of Dermatology and Syphilology:

During 1938 there were two meetings of the board, one in San Francisco in June and the other in St. Louis in November at the time of the meeting of the academy.

Thirty-two candidates were examined in San Francisco and thirty-four in St. Louis, making a total of sixty-six examined. Of this number, twelve were conditioned, six failed and forty-eight passed. It is of interest to note that a total of 278 have been examined. There have been forty failures to pass the examination in the eight examinations which the board has conducted, and thirty-eight have been conditioned. About one-third of these have been certified on subsequent reexamination. There has been a total of 531 applications, and there are now 415 diplomates.

At the San Francisco meeting the resignation of Dr. Howard Morrow, submitted on account of illness, was accepted with great regret, and Dr. Paul A. O'Leary was elected for the unexpired term. At this meeting also the matter of representation of the Academy of Dermatology and Syphilology on the board was discussed. It was voted to ask the academy to designate three members for the board, subject to ratification by the American Dermatological Association and the Section on Dermatology and Syphilology of the American Medical Association, of the new plan whereby the board shall consist of a total of nine members, three each from the American Dermatological Association, the Section on Dermatology and Syphilology and the Academy of Dermatology and Syphilology, to take effect when ratified by the last one of these three.

At the St. Louis meeting Dr. George M. MacKee, New York, tendered his resignation from the board on account of illness. His resignation was accepted with great regret and Dr. J. Gardner Hopkins of New York was elected for the unexpired term. At this meeting the matter of a syllabus dealing with graduate training in dermatology and with the qualifications of preceptors were major items of business.

During the last four years ten drafts of a syllabus for graduate training have been submitted to the board for discussion. There has been a great deal of correspondence and much serious discussion over such a syllabus, and this syllabus has just been published and is now ready for distribution. The qualifications of preceptors and application blanks will be available within a short time.

At the recent meeting of the Advisory Board for Medical Specialties in Chicago in February, at which representatives of all the specialty boards met with representatives of other national organizations concerned with graduate training, several matters of importance developed.

It was voted to publish a directory of specialists containing both alphabetical and geographic listing, together with information about each board. The various boards are contributing to the publication of this directory on a refunding basis. This directory has every prospect of being self supporting when once started. Second in importance was the matter of cooperation in the evaluation of training centers as agreed on between the Council on Medical Education and Hospitals and the American Board of Radiology. The American Board of Pathology has since adopted a similar cooperative evaluation, and the other boards will probably cooperate with the Council in the actual inspection and approval of the various opportunities for graduate training throughout the country, especially with regard to the three year training requirement which has been adopted by all the specialty boards. This board is at present engaged in the study of this matter, and conferences will be held with members of the Council at this A. M. A. meeting. A third matter of importance is the announcement of a National Council of Medical Education, Hospitals and Licensure, on which the Advisory Board for Medical Specialties will have representation. This body has been created by representatives of various national organizations to deal with various phases of medical education, especially the cooperative consideration of those problems and programs of professional training with which more than one organization is concerned.

Submitted by the American Board of Dermatology and Syphilology.

C. GUY LANE, Secretary.

On motion by Dr. R. C. Jamieson, Detroit, seconded by Dr. Paul A. O'Leary, Rochester, Minn., it was voted to accept the report of the American Board of Dermatology and Syphilology.

Dr. Paul A. O'Leary, Rochester, Minn., reported for the Committee on the International Congress on Dermatology and Syphilology, as follows:

Dr. Tauber has discussed the financial situation and I think this sheet that is being passed around will probably bring out some factors that explain to you why we want $15,000 from the dermatologists. We have a tentative budget of approximately $50,000 for the congress and I know that when I say that there will be men around the country who will immediately think that we are going to import some foreign dermatologists. Dr. Tauber made that point very clear and I would like to reemphasize it again, because the men still seem to have the idea in their mind that $50,000 is too much money for a congress. I believe that as you look over the budget you will find we have been very conservative in our estimate in most of the appropriation, so that the $15,000 that we are asking for from the American dermatologists is not enough. At the moment we have an outside source that may help us very materially. If it will help us, it will be a very fine thing. If it will not help us, in other words if we do not be the contribution we are anticipating, there may be further effort to raise money from among you men. However, we don't feel that will be necessary.

I want to say that my enthusiasm during the past year has varied from hot to cold in regard to the congress, primarily because of the lack of reaction on the part of the foreigners up, I might say, until about two months ago. Since that time I have had some fifty applications for space on the volunteer program. In other words, there has been apparently, as far as correspondence might lead one to believe, a rather definite change in favor, or you might say there has been a definite evidence of demonstration of enthusiasm perhaps for the congress. So I feel that during the past two months at least we have had sufficient evidence to believe that we shall have a very definite degree of enthusiasm from the European dermatologists.

There was a notice in the last issue of the *Archives* asking for men to request a place on the volunteer program. The program is made essentially in three parts. There is to be a group of symposiums, about eleven different selected subjects, for which invited speakers from the world have been asked to participate and practically all the symposiums are filled at the moment. In fact, the only ones that have not been selected are the American.

In addition, there will be a series of volunteer papers. By volunteer papers we mean the afternoon sessions, because the symposiums will be held in the morning. In other words, there will be a one ring circus in the morning and in the afternoon probably two and maybe three. We hope we can eliminate the third and limit it to two sessions.

There will be in addition a symposium on syphilis and a meeting of the International Committee against Venereal Disease which will incorporate a few papers on gonorrhea. So that those of you who have an interest or have a thought of presenting a paper before the congress, I hope you will send in an application immediately, however not other than a title. In other words, just display, if you will, to us, now the fact that you are interested and that you may present or would like to present something before the congress.

The one different thing we are endeavoring to insist on as a program committee is that papers be limited to original work. We are not anxious for a historical review of some old dermatosis nor are we interested in a single case report; but we are interested, of course, in receiving applications from individuals who have at least an original contribution to make. So will you send those in?

At the same time, of course, we are interested in a scientific exhibit. Dr. Joseph Gardner Hopkins is going to be in charge of that exhibit and I know he feels as I do, if you will let us know as soon as possible so we may get some idea as to the amount of space necessary, it will help very materially in the organization.

On motion by Dr. Elmore B. Tauber, Cincinnati, seconded by Dr. Richard S. Weiss, St. Louis, it was voted to adopt Dr. O'Leary's report.

Dr. C. Guy Lane, Boston, made the following report for the Committee on Industrial Dermatoses:

I simply want to make a brief report of the Committee on Industrial Dermatoses, which has been acting during the past three or four years. A joint meeting was held yesterday with the committee of the American Dermatological Association and representatives of the Public Health Service. Their report of the dermatologic activities of the Council on Industrial Health was read and discussed. Plans for participation in the industrial symposium of the International Congress were also presented and discussed at that time.

The formulation of the standardizing definitions and criteria for diagnosis of industrial dermatoses was begun. There was discussion of plans for coordinating the activity in this par-

ticular field with the American Medical Association activities and those of the Public Health Service as well.

On motion by Dr. Paul A. O'Leary, Rochester, Minn., seconded by Dr. Elmore B. Tauber, Cincinnati, it was voted to adopt Dr. Lane's report.

Under new business, Dr. Fred D. Weidman, Philadelphia, stated that it would be desirable to take action on the recommendation of Dr. Lane about the members on the American Board of Dermatology and moved that the executive committee be given power to act in the matter of designation of members to the American Board of Dermatology, in accordance with the principles outlined in Dr. Lane's report, particularly with reference to the American Academy.

Dr. C. Guy Lane, Boston, requested that the motion include the approval of the plan to have only three members from this section as well as from the other three national organizations and the details of arrangement of that plan be left to the executive committee. The motion was seconded, as amended, by Dr. Hamilton Montgomery, Rochester, Minn., and carried.

Drs. Joseph V. Klauder and Alfred Cowan, Philadelphia, presented a paper on "Corneal Examination and Slit Lamp Microscopy in Diagnosis of Late Congenital Syphilis Especially in Adults." Discussed by Drs. James R. Driver, Cleveland; John McLeod, Kansas City, Mo., and Joseph V. Klauder, Philadelphia.

Drs. G. Marshall Crawford and Leon F. Ray, Boston, presented a paper on "Serologic Discrepancies in Syphilis." Discussed by Drs. C. Guy Lane, Boston; G. V. Kulchar, San Francisco; Charles R. Rein, New York; Arthur G. Schoch, Dallas, Texas, and G. Marshall Crawford, Boston.

Drs. Charles R. Rein and Fed Wise, New York, presented a paper on "Mapharsen in Treatment of Syphilis in Office Practice, A Study Based on 2,342 Injections in 113 Patients." Discussed by Drs. Girsch D. Astrachan, New York; Harry M. Robinson, Baltimore; S. William Becker, Chicago; Leon Goldman, Cincinnati, and Charles R. Rein, New York.

Dr. Robert B. Greenblatt, August, Ga., presented a paper on "Experimental and Clinical Granuloma Inguinale." Discussed by Drs. Harry M. Robinson, Baltimore; S. William Becker, Chicago; Arthur G. Schoch, Dallas, Texas; Samuel Goldblatt, Cincinnati; Fred D. Weidman, Philadelphia; W. A. De Monbreun, Nashville, Tenn., and Robert B. Greenblatt, Augusta, Ga.

Drs. Kathleen B. Muir, Evangeline Stenhouse and S. William Becker, Chicago, presented a paper on "The Action of Sodium Thiosulfate, Sodium p-Sulphydril Phenyl Sulfonate and Sodium Formaldehyde Sulfoxylate in Arsenical and Mercurial Poisoning in Rabbits." Discussed by Drs. Charles C. Dennie, Kansas City, Mo.; Samuel Goldblatt, Cincinnati, and S. William Becker, Chicago.

Dr. Theodore Cornbleet, Chicago, read a paper on "Cutaneous Carbohydrates: I. The Normal Skin." Discussed by Drs. G. V. Kulchar, San Francisco; M. B. Sulzberger, New York, and Theodore Cornbleet, Chicago.

Dr. John H. Talbott, Boston, read a paper on "Pemphigus." Discussed by Drs. Richard S. Weiss, St. Louis; C. Guy Lane, Boston; M. F. Engman, St. Louis; M. B. Sulzberger, New York; Theodore Cornbleet, Chicago, and John H. Talbott, Boston.

FRIDAY MAY 19—AFTERNOON

The chairman stated that he had received a communication inviting the members to attend the fiftieth anniversary meeting of the German Dermatological Society, August 19-21, at Würzburg, Germany.

Dr. Francis E. Senear, Chicago, moved that the chairman of the section appoint a committee of three to cooperate with those appointed from the American Dermatological Association, the Academy and the investigative society, on the matter of administration of the new act covering foods, drugs and cosmetics, with regard to reporting irritants which produce dermatoses and whereby such information would be made available. The motion was seconded by Dr. R. C. Jamieson, Detroit, and carried.

The chairman then appointed the following committee: Drs. Francis E. Senear, Chicago; C. Guy Lane, Boston, and Nelson Paul Anderson, Los Angeles.

The following officers were elected: chairman, Dr. John G. Downing, Boston; vice chairman, Dr. Richard S. Weiss, St. Louis; Secretary, Dr. C. F. Lehmann, San Antonio, Texas; delegate, Dr. Clyde Cummer, Cleveland; alternate, Dr. Harold N. Cole, Cleveland; chairman of Scientific Exhibit Committee, Dr. Hamilton Montgomery, Rochester, Minn.; representative to the American Board of Dermatology and Syphilology, Dr. Joseph Gardner Hopkins, New York.

Drs. H. L. Williams Jr., Hamilton Montgomery and William N. Powell, Rochester, Minn., presented a paper on "Dermatitis of the Ear." Discussed by Drs. James Herbert Mitchell, Chicago; M. F. Engman, St. Louis, and Hamilton Montgomery, Rochester, Minn.

Drs. William Howard Hailey and Hugh E. Hailey, Atlanta, Ga., presented a paper on "Pruritus Ani et Vulvae." Discussed by Drs. Carl W. Laymon, Minneapolis; James Herbert Mitchell, Chicago; Claude C. Tucker, Wichita, Kan.; Clark W. Finnerud, Chicago; Hamilton Montgomery, Rochester, Minn.; J. L. Kobacker, Toledo, Ohio; Joseph Grindon Sr., St. Louis, and William Howard Hailey, Atlanta, Ga.

Drs. Udo J. Wile and Harry L. Arnold Jr., Ann Arbor, Mich., presented a paper on "The Senear-Usher Syndrome." Discussed by Drs. Francis E. Senear, Chicago; Hamilton Montgomery, Rochester, Minn.; S. William Becker, Chicago, and Harry L. Arnold Jr., Ann Arbor, Mich.

Dr. Leslie P. Barker, New York, read a paper on "Generalized Herpes Zoster." Discussed by Drs. Nelson Paul Anderson, Los Angeles; Joseph Grindon Jr., St. Louis, and Leslie P. Barker, New York.

Dr. Onis G. Hazel, Oklahoma City, read a paper on "Poikiloderma Atrophicans Vasculare." Discussed by Drs. Fred M. Jacob, Pittsburgh; Fred D. Weidman, Philadelphia, and Onis G. Hazel, Oklahoma City.

On motion by Dr. Francis E. Senear, Chicago, seconded by Fred D. Weidman, Philadelphia, a vote of thanks was extended by a rising vote to the local dermatologists for a pleasant and profitable meeting.

On motion by Dr. Joseph Grindon Sr., St. Louis, seconded by several members, a vote of thanks was extended to the chairman, vice chairman and secretary for the splendid way they conducted the meetings.

SECTION ON PREVENTIVE AND INDUSTRIAL MEDICINE AND PUBLIC HEALTH

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. I. C. Riggin, Richmond, Va.

Dr. I. C. Riggin, Richmond, Va., read the chairman's address, entitled "Expansion of Functions and Responsibilities of Health Departments."

Dr. Louis F. Bishop Jr., New York, read a paper on "Traumatic Heart Disease with Particular Reference to Injury." Discussed by Drs. Ray W. Kissane, Columbus, Ohio, and Louis F. Bishop Jr., New York.

Dr. Joseph W. Mountin and Harold F. Dorn, Washington, D. C., presented a paper on "Some Peculiarities in the Geography of Cancer." Discussed by E. V. Cowdry, Ph.D., St. Louis, and Drs. J. N. Baker, Montgomery, Ala.; Frederick G. Murray, Cedar Rapids, Iowa; John A. Ferrell, New York; A. G. Henderson, Imboden, Ark., and Joseph W. Mountin, Washington, D. C.

On motion made by Dr. Leopold Brahdy, New York, and seconded by Dr. John A. Ferrell, New York, the chairman was authorized to appoint a committee to study with the executive committee a tentative draft of Suggested School Health Policies and make a report to be forwarded to Dr. W. W. Bauer, director of the Bureau of Health Education of the American Medical Association. The chairman appointed the executive committee members Drs. L. D. Bristol, New York, Robert T. Legge, Berkeley, Calif.; and I. C. Riggin, Richmond, Va., and, in addition, Drs. Harold S. Diehl, Minneapolis; John A. Ferrell, New York, and J. N. Baker, Montgomery, Ala.

Dr. John H. Powers, Cooperstown, N. Y., read a paper on "The Hazards of Farming." Discussed by Drs. F. P. Helm, Topeka, Kan.; A. Girard Cranch, New York; Leopold Brahdy,

New York; Joseph W. Mountin, Washington, D. C.; J. N. Baker, Montgomery, Ala., and John H. Powers, Cooperstown, N. Y.

Drs. Mark A. Glaser and Frederick P. Shafer, Los Angeles, presented a paper on "Depressed Skull Fractures." Discussed by Drs. John H. Powers, Cooperstown, N. Y., and Mark A. Glaser, Los Angeles.

THURSDAY, MAY 18—MORNING

Dr. Julien E. Benjamin, Cincinnati, read a paper on "A Study of the Pneumonias with Reference to Overcrowding and Cross Infection." Discussed by Drs. Jesse G. M. Bullowa, New York; Emil Bogen, Olive View, Calif., and Julien E. Benjamin, Cincinnati.

Dr. Leopold Brahdy, New York, read a paper on "Tuberculosis Among Hospital Personnel." Discussed by Drs. C. D. Selby, Detroit; Harold S. Diehl, Minneapolis; Camille Kereszturi, New York, and Leopold Brahdy, New York.

The chairman presented the following report made by the committee appointed to consider the Suggested School Health Policies tentative draft:

This statement, to delineate the responsibilities of school health programs and to relate the school health program to the health programs or health activities of other groups, is hereby approved in general as a distinctly worthwhile set of principles.

We would like to recommend consideration of the following points:

(*a*) On page 7 we would suggest that noise be mentioned as a disturbing factor in school lunch rooms.

(*b*) On page 16 we question the statement that it is undesirable to conduct immunization clinics in schools. Oftentimes this is the only way it can be done.

(*c*) On page 19 we question the diseases mentioned as not being prevented by "healthful living." If we understand the meaning of "healthful living," we suggest a modification here.

(*d*) On page 20 we suggest the words "should prepare" in place of "are preparing" (as marked).

(*e*) On page 27 we suggest that thoroughness of pupil examinations be emphasized rather than frequency of examinations.

(*f*) On page 28 we suggest that investigation of cases entitled to clinic service for their children be not restricted to a "medical social worker."

(*g*) Lastly, we would recommend that the value of cumulative individual health records of school children be stressed and an outline of principles involved be described.

Respectfully submitted.

JOHN. A. FERRELL.
J. N. BAKER.
I. C. RIGGIN.
L. D. BRISTOL.
H. S. DIEHL.
W. A. SAWYER.

On motion by Dr. John L. Rice, New York, seconded by Dr. J. N. Baker, Montgomery, Ala., it was voted that the report be approved.

The report of the delegate was made by Dr. Stanley H. Osborn, Hartford, Conn.

On motion by Dr. Harold S. Diehl, Minneapolis, seconded by Dr. John A. Ferrell, New York, it was voted that the action taken last year relative to the term of service of the delegate to the House of Delegates be rescinded.

Dr. Robert E. Plunkett, Albany, N. Y., read a paper on "Tuberculosis Control." Discussed by Drs. Leverett D. Bristol, New York; Earl F. Morris, Hays, Kan.; John L. Rice, New York, and Robert E. Plunkett, Albany, N. Y.

Drs. Harold T. Hyman, Louis Chargin, John L. Rice and William Leifer, New York, presented a paper on "The Intravenous Drip Method of Therapy Applied to Syphilis." Discussed by Drs. R. A. Vonderlehr, Washington, D. C.; George V. Kulchar, San Francisco; Louis Chargin, New York, and Earl F. Morris, Hays, Kan.

Dr. Samuel Goldblatt, Cincinnati, read a paper on "The Relationship of Syphilis to Tuberculosis." Discussed by Drs. Charles C. Dennie, Kansas City, Mo.; Emil Bogen, Olive View, Calif., and Samuel Goldblatt, Cincinnati.

FRIDAY, MAY 19—MORNING

The following officers were elected: chairman, Dr. Harold S. Diehl, Minneapolis; vice chairman, Dr. Clarence D. Selby, Detroit; secretary, Dr. W. A. Sawyer, Rochester, N. Y.; executive committee: Dr. Robert T. Legge, Berkeley, Calif.; Dr. I. C. Riggin, Richmond, Va., and Dr. Harold S. Diehl, Minneapolis; delegate, Dr. Stanley H. Osborn, Hartford, Conn.; alternate, Dr. R. R. Sayers, Washington, D. C.; chairman, Committee on Section Exhibit, Dr. P. A. Davis, Akron, Ohio.

On motion by Dr. John A. Ferrell, New York, seconded by Dr. C. M. Peterson, Chicago, it was voted that the incoming chairman be requested to appoint a committee of two or four to make a study of the section and its activities and of the conditions responsible for the small attendance at the section sessions, the committee to seek the aid of the Chicago office in comparing the activities of the section with other sections and securing cooperation in formulating a program that will bring a creditable attendance to the section meetings.

Dr. Edward Matzger, San Francisco, read a paper on "Industrial Importance of Allergic Diseases to the Southern Pacific Railroad Company." *No discussion.*

Dr. C. C. Burlingame, Hartford, Conn., read a paper on "Hard Facts About Psychiatry." Discussed by Drs. W. A. Sawyer, Rochester, N. Y.; John A. Ferrell, New York, and C. C. Burlingame, Hartford, Conn.

Dr. P. A. Davis, Akron, Ohio, read a paper on "Present Status of Benzene." Discussed by Drs. A. Girard Cranch, New York; Louis Schwartz, New York, and P. A. Davis, Akron, Ohio.

Dr. Paul A. Neal, Washington, D. C., read a paper on "Dermatitis Among Plate Printers." Discussed by Drs. Louis Schwartz, New York, and Paul A. Neal, Washington, D. C.

Dr. R. V. Ellis, Minneapolis, read a paper on "Pollinosis as a Problem in Preventive Medicine." Discussed by Drs. John M. Sheldon, Ann Arbor, Mich.; Louis Schwartz, New York; John A. Ferrell, New York, and R. V. Ellis, Minneapolis.

SECTION ON UROLOGY

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9:05 by the chairman, Dr. William P. Herbst, Washington, D. C.

Secretary Vincent J. O'Conor, Chicago, read a report from Dr. Alfred I. Folsom, chairman of the American Board of Urology.

The following papers were read as a symposium on "Injuries of the Urinary Tract":

Dr. Franklin Farman, Los Angeles: "Diagnostic and Operative Factors in Traumatic Rupture of the Kidney."

Dr. George C. Prather, Boston: "Clinical Observations Regarding Traumatic Conditions of the Kidney."

Drs. Carl F. Rusche and S. K. Bacon, Los Angeles: "Injuries of the Ureter."

These three papers were discussed by Drs. Harry C. Rolnick, Chicago; James C. Sargent, Milwaukee; Charles Y. Bidgood, Hartford, Conn.; John E. Heslin, Albany, N. Y.; Otto J. Wilhelmi, St. Louis; Franklin Farman, Los Angeles, and Carl F. Rausche, Los Angeles.

Dr. E. J. McCague, Pittsburgh: "Intraperitoneal and Extraperitoneal Rupture of the Urinary Bladder."

Dr. William R. Hornaday, Des Moines, Iowa: "Care of Traumatic Injuries of the Male Urethra."

These two papers were discussed by Drs. A. J. Scholl, Los Angeles; Edward Lester Merritt, Fall River, Mass., and William R. Hornaday, Des Moines, Iowa.

Dr. George H. Ewell, Madison, Wis.: "Traumatic 'Epididymo-Orchitis.'" Discussed by Drs. Miley B. Wesson, San Francisco; Edward Cathcart, Detroit; Leon Herman, Philadelphia, and George H. Ewell, Madison, Wis.

THURSDAY, MAY 18—MORNING

Dr. Roy E. Brackin, Kenilworth, Ill., read a paper on "A New Method of Uretero-Intestinal Anastomosis with Utilization of Peritoneum." Discussed by Drs. Waltman Walters, Rochester, Minn., and Roy E. Brackin, Kenilworth, Ill.

Dr. James T. Priestley, Rochester, Minn., read a paper on "Survival Following Removal of Malignant Renal Neoplasms." Discussed by Dr. William P. Herbst, Washington, D. C.

Dr. William P. Herbst, Washington, D. C., read the chairman's address, entitled "Renal Tuberculosis as a Community Problem."

Dr. Charles M. McKenna, Chicago, read a paper on "Hypospadias (in the Male): The Operative Technic for the Correction of Penile Deformity and Reconstruction of the Urethra." Discussed by Drs. Clinton K. Smith, Kansas City, Mo.; Vincent J. O'Conor, Chicago; Vilray P. Blair, St. Louis; Frederic E. B. Foley, St. Paul, and Charles M. McKenna, Chicago.

Dr. Max L. Rosenheim of London, England, addressed the section.

Dr. William F. Lower, Cleveland, read a paper on "Clinical Aspects of the Endocrine Functions of the Testes in Man."

Dr. James F. McCahey, Philadelphia, read a paper on "The Endocrine Function of the Testis."

These two papers were discussed by Drs. S. A. Vest, Baltimore; Walter M. Kearns, Milwaukee; William E. Lower, Cleveland, and James F. McCahey, Philadelphia.

FRIDAY, MAY 19—MORNING

The following officers were elected: chairman, Dr. Frederic E. B. Foley, St. Paul; vice chairman, Dr. Thomas J. Kirwin, New York; secretary, Dr. Vincent J. O'Conor, Chicago; delegate, Dr. H. Carey Bumpus, Pasadena, Calif.; alternate, Dr. George C. Prather, Boston.

Drs. Eli A. Miller, Denver, and Mischa J. Lustok, Spivak, Colo., presented a paper on "Genital Tuberculosis." Discussed by Drs. Homer C. Hamer, Indianapolis, and Mischa J. Lustok, Spivak, Colo.

The following papers were read as a symposium on "Urinary Calculi":

Dr. Charles C. Higgins, Cleveland: "Factors in Recurrence of Renal Calculi"

Dr. Rubin Flocks, Iowa City: "Calcium and Phosphorus Excretion in the Urine of Patients with Renal or Ureteral Calculi."

Drs. Herman L. Kretschmer and Ralph C. Brown, Chicago: "Do Alkalis Used in the Treatment of Peptic Ulcer Cause Kidney Stones?"

These three papers were discussed by Drs. John Morrissey, New York; Roy J. Holmes, Miami, Fla.; Charles C. Higgins, Cleveland, and Ralph C. Brown, Chicago.

Dr. Gershom J. Thompson, Rochester, Minn., read a paper on "The Treatment of Ureteral Calculus with Particular Reference to Transurethral Manipulation."

Dr. John Duff, New York, read a paper on "Ureteral Meatotomy: Its Significance and a New Technic."

These two papers were discussed by Drs. E. P. Alyea, Durham, N. C.; H. Carey Bumpus, Pasadena, Calif.; Frederic E. B. Foley, St. Paul, and Vincent J. O'Conor, Chicago.

The section expressed its appreciation to the St. Louis Urological Society for its hospitality.

SECTION ON ORTHOPEDIC SURGERY

WEDNESDAY, MAY 17—MORNING

The meeting was called to order at 9 o'clock by the chairman, Dr. Oscar L. Miller, Charlotte, N. C.

Dr. E. J. Berkheiser, Chicago, read a paper on "Excision of Patella in Cases of Hypertrophic Arthritis." Discussed by Drs. A. H. Meyer, Memphis, Tenn.; Jacob Kulowski, St. Joseph, Mo.; Frank Murphy, Chicago; J. Albert Key, St. Louis; John P. Stump, New York; Garrett Pipkin, Kansas City, Mo., and E. J. Berkheiser, Chicago.

Dr. Francis M. McKeever, Los Angeles, read a paper on "Tuberculosis of the Knee in Infancy and Childhood." Discussed by Drs. W. P. Blount, Milwaukee; R. B. Osgood, Boston; Halford Hallock, New York; Frank R. Ober, Boston, and Francis M. McKeever, Los Angeles.

Drs. Edward L. Compere, Samuel W. Banks and William N. Krigsten, Chicago, presented a paper on "Regeneration of the Growth Epiphyses of Long Bones." Discussed by Drs. Willis C. Campbell, Memphis, Tenn.; J. Albert Key, St. Louis, and William N. Krigsten, Chicago.

Drs. Fremont A. Chandler and John R. Norcross, Chicago, presented a paper on "Sympathicoblastoma: A Report of Four Cases." Discussed by Drs. Frank R. Ober, Boston; G. K. Carpenter, Nashville, Tenn., and Fremont A. Chandler, Chicago.

Dr. Willis C. Campbell, Memphis, Tenn., delegate to the House, presented a report on an action of the House of Delegates and received a vote of support of his action from the section.

Dr. Joseph A. Freiberg, Cincinnati, read a paper on "Low Back Pain: Correlation of the Signs and Symptoms of the Various Noninfectious Lesions." Discussed by Drs. Philip Lewin, Chicago; G. C. Battalora, New Orleans; Earl D. McBride, Oklahoma City, and Joseph A. Freiberg, Cincinnati.

Drs. Carl E. Badgley and N. John Rowe Jr., Ann Arbor, Mich., presented a paper on "The Cook Fenestrated Jacket for Correction of Scoliosis." Discussed by Drs. C. H. Crego Jr., St. Louis; L. G. Howard, Boston; Earl D. McBride, Oklahoma City; Charles A. Stone, St. Louis; J. Albert Key, St. Louis, and Carl E. Badgley, Ann Arbor, Mich.

The following were appointed as a nominating committee; Dr. Robert D. Schrock, Omaha, chairman; Dr. L. G. Howard, Boston, and Dr. Francis M. McKeever, Los Angeles.

THURSDAY, MAY 18—MORNING

Dr. Halford Hallock, New York, read a paper on "Reconstructive and Stabilizing Surgery in the Treatment of Residual Suppurative Arthritis of the Hip Joint: A Study of Forty-Five Unselected Cases." Discussed by Drs. J. Albert Key, St. Louis; Frank D. Dickson, Kansas City, Mo.; Edwin W. Ryerson, Chicago, and Halford Hallock, New York.

Dr. Edwin W. Ryerson, Chicago, read a paper on "Excision of Scapula: Report of a Case Showing Excellent Functional Result." Discussed by Drs. W. B. Carrell, Dallas, Texas; J. Albert Key, St. Louis, and Edwin W. Ryerson, Chicago.

Drs. A. R. Shands Jr., Wilmington, Del., and Lenox D. Baker, Durham, N. C., presented a paper on "Acute Osteomyelitis with Staphylococcemia: A Clinical Report on the Use of Antitoxin in Its Treatment." Discussed by Drs. James B. Weaver, Kansas City, Mo.; Ben L. Schoolfield, Dallas, Texas, and Lenox D. Baker, Durham, N. C.

Dr. Oscar L. Miller, Charlotte, N. C., read the chairman's address, entitled "Simplified Internal Fixation of Inlay and Onlay Bone Grafts."

Drs. Ralph K. Ghormley and Robert D. Fairchild, Rochester, Minn., presented a paper on "Diagnosis and Treatment of Slipped Epiphyses." Discussed by Drs. Beckett Howorth, New York; Walter P. Blount, Milwaukee; W. B. Carrell, Dallas, Texas; Eugene M. Regen, Nashville, Tenn., and Ralph K. Ghormley, Rochester, Minn.

Dr. Rex L. Diveley, Kansas City, Mo. read a paper on "Imbalance of the Foot." Discussed by Drs. J. E. M. Thomson, Lincoln, Neb.; H. R. Bohlman, Baltimore; Willis C. Campbell, Memphis, Tenn.; Ben L. Schoolfield, Dallas, Texas; Oscar L. Miller, Charlotte, N. C., and Rex L. Diveley, Kansas City, Mo.

FRIDAY, MAY 19—MORNING

Drs. Vernon P. Thompson and John S. Stephens, Los Angeles, presented a paper on "Compression Reconstruction of Recent Intracapsular Femoral Neck Fractures: Internal Fixation by Universal Length Z Nail." Discussed by Drs. V. L. Hart, Minneapolis; F. W. Carruthers, Little Rock, Ark.; Joseph A. Freiberg, Cincinnati, and John S. Stephens, Los Angeles.

Dr. W. K. West, Oklahoma City, read a paper on "Severe Fractures of the Upper Ulna." Discussed by Drs. J. T. O'Ferrall, New Orleans; J. Albert Key, St. Louis; Walter Stuck, San Antonio, Texas; Charles A. Stone, St. Louis, and W. K. West, Oklahoma City.

Dr. Paul C. Colonna and Frederick H. vom Saal, Oklahoma City, presented a paper on "A Study of Amputations in the Lower Extremities." Discussed by Drs. R. G. Packard, Denver; James R. Elliott, Kansas City, Mo.; Ralph K. Ghormley, Rochester, Minn.; J. Albert Key, St. Louis; Lenox D. Baker, Durham, N. C.; Robert D. Schrock, Omaha; S. Perry Rogers, Chicago, and Frederick H. vom Saal, Oklahoma City.

The following officers were elected: chairman, R. V. Funsten, Charlottesville, Va.; vice chairman, J. Albert Key, St. Louis; secretary, Guy A. Caldwell, New Orleans; executive committee: John Dunlop, Pasadena, Calif., Oscar L. Miller, Charlotte, N. C., and Robert V. Funsten, Charlottesville, Va.; delegate, Willis C. Campbell, Memphis, Tenn.; alternate, James Archer O'Reilly, St. Louis; nominees to the American Board of Orthopedic Surgery, Fremont A. Chandler, Chicago, and Ralph K. Ghormley, Rochester, Minn.

Dr. Robert D. Schrock, Omaha, read a paper on "Sideswipe Fractures at the Elbow." Discussed by Drs. G. O. Eaton, Baltimore; R. C. Robertson, Chattanooga, Tenn.; Howard B. Shorbe, Oklahoma City, and Robert D. Schrock, Omaha.

Dr. Clay Ray Murray, New York, read a paper on "Primary Operative Reduction of Fractures of Long Bones as a Method of Choice: An Evaluation of Principles." Discussed by Drs. Paul B. Magnuson, Chicago; H. Earle Conwell, Birmingham, Ala.; M. L. Klinefelter, St. Louis; J. Albert Key, St. Louis; F. W. Carruthers, Little Rock, Ark., and Clay Ray Murray, New York.

Dr. L. D. Smith, Milwaukee, read a paper on "Treatment of Supracondylar Fractures of the Femur by Manipulation and Acute Flexion." Discussed by Drs. J. D. Wilson, Columbus, Ohio; Robert D. Schrock, Omaha, and L. D. Smith, Milwaukee.

SECTION ON GASTRO-ENTEROLOGY AND PROCTOLOGY

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order at 2 o'clock by the chairman, Dr. Descum C. McKenney, Buffalo.

The following papers were read as a symposium on "Aids to the Management of Peptic Ulcer":

Drs. A. L. Levin and Morris Shushan, New Orleans: "A Comparative Study of Methods Utilized to Determine the Presence of Ulceration in the Gastrointestinal Tract."

Drs. M. Hill Metz, Robert W. Lackey, P. E. Wigby, A. B. Small and C. O. Patterson, Dallas, Texas: "Peptic Ulcer Treated by Posterior Pituitary Preparations: Clinical and Experimental Observations."

Dr. Manfred Kraemer, Newark, N. J.: "The Use of Hydrated Trisilicate of Magnesium for Peptic Ulcer."

These three papers were discussed by Drs. Walter L. Palmer, Chicago; Maurice Feldman, Baltimore; Sidney A. Portis, Chicago; Henry A. Rafsky, New York; George M. Underwood, Dallas, Texas; A. L. Levin, New Orleans; M. Hill Metz, Dallas, Texas, and Manfred Kraemer, Newark, N. J.

Dr. Porter P. Vinson, Richmond, Va., read a paper on "The Management of Benign Strictures of the Esophagus." Discussed by Dr. John H. Fitzgibbon, Portland, Ore.

Drs. Frank H. Connell and Harry T. French, Hanover, N. H., presented a paper on "The Incidence and Results of Treatment in Subclinical Amebiasis." Discussed by Drs. James L. Borland, Jacksonville, Fla.; George B. Lake, Waukegan, Ill.; A. L. Levin, New Orleans; Walter L. Palmer, Chicago, and Frank H. Connell, Hanover, N. H.

The following papers were read as a symposium on "Systemic Conditions with Gastrointestinal Symptoms":

Drs. Lester M. Morrison and William A. Swalm, Philadelphia: "The Role of the Gastrointestinal Tract in the Production of Cardiac Symptoms."

Drs. Sidney A. Portis and Jacob Kasanin, Chicago: "Psychosomatic Factors Concerned in Diarrhea."

Dr. E. L. Tuohy, Duluth, Minn.: "Geriatrics: Its Relation to an Adequate Energy Producing and Protective Diet."

These three papers were discussed by Dr. Seale Harris, Birmingham, Ala.

THURSDAY, MAY 18—AFTERNOON

The following officers were elected: chairman, Dr. A. H. Aaron, Buffalo; vice chairman, Dr. Frank C. Yeomans, New York; secretary, Dr. J. Arnold Bargen, Rochester, Minn.; executive committee: Dr. Henry L. Bockus, Philadelphia, Dr. Descum C. McKenney, Buffalo, and Dr. A. H. Aaron, Buffalo; delegate, Dr. Curtice Rosser, Dallas, Texas; alternate, Dr. L. A. Buie, Rochester, Minn.; chairman, Committee on Section Exhibit, Dr. Sara M. Jordan, Boston.

The following papers were read as a symposium on "Therapeutic Advances in Disease of the Ileocecal Region":

Drs. J. Shelton Horsley, John S. Horsley Jr. and Guy W. Horsley, Richmond, Va.: "Appendicitis: Newer Methods of Treatment."

Drs. Thew Wright, A. H. Aaron, J. Sutton Regan and Elmer Milch, Buffalo: "The Management of Patients with Diffuse Peritonitis Caused by Perforated Appendicitis."

Dr. Benjamin M. Bernstein, Brooklyn: "Ileocecal Spasm: The Cause for the Appendicular Syndrome."

These three papers were discussed by Drs. Frederick A. Coller, Ann Arbor, Mich.; Sidney A. Portis, Chicago; Niels C. Klendshoj, Buffalo; Henry A. Rafsky, New York; Sara M. Jordan, Boston; M. Pinson Neal, Columbia, Mo.; J. Shelton Horsley, Richmond, Va.; A. H. Aaron, Buffalo, and Benjamin M. Bernstein, Brooklyn.

The following papers were read as a symposium on "Studies on Cancer at Different Ages":

Dr. Andrew B. Rivers, Rochester, Minn.: "The Importance of Carcinoma as a Cause of Indigestion."

Drs. Curtice Rosser and J. G. Kerr, Dallas, Texas: "Cancer of the Rectum in Young Persons."

These two papers were discussed by Drs. Burrill B. Crohn, New York; Henry A. Rafsky, New York; John M. Blackford, Seattle; Louis J. Hirschman, Detroit; Andrew B. Rivers, Rochester, Minn., and Curtice Rosser, Dallas, Texas.

The following papers were read as a symposium on "Important Points in the Management of Neoplasms of the Large Intestine":

Drs. Neil W. Swinton and Shields Warren, Boston: "Polyps of the Colon and Rectum and Their Relation to Malignancy."

Drs. Jerome M. Lynch and G. Johnson Hamilton, New York: "The Lynch versus the Miles Operation."

Dr. W. Wayne Babcock, Philadelphia: "The Advantages of Perineal Over Abdominal Colostomy with Technic for Transferring the Abdominal Opening to the Perineum."

These three papers were discussed by Drs. Claude F. Dixon, Rochester, Minn.; William J. Martin Jr., Louisville, Ky.; Louis J. Hirschman, Detroit; Frank H. Lahey, Boston; Neil W. Swinton, Boston; Jerome M. Lynch, New York, and W. Wayne Babcock, Philadelphia.

FRIDAY, MAY 19—AFTERNOON

A joint meeting was held with the Section on Radiology. The proceedings are reported in the minutes of that section.

SECTION ON RADIOLOGY

WEDNESDAY, MAY 17—AFTERNOON

The meeting was called to order by the chairman, Dr. R. G. Taylor, Los Angeles.

The chairman appointed Dr. Edward L. Jenkinson, Chicago, to serve on the executive committee in the absence of Dr. B. R. Kirklin, Rochester, Minn.

Drs. W. A. Altemeier and H. C. Jones, Detroit, presented a paper on "Experimental Peritonitis: Its Prevention by Roentgen Therapy." Discussed by Dr. J. P. Pratt, Detroit.

Drs. George P. Robb and Israel Steinberg, New York, presented a paper on "Visualization of the Chambers of the Heart, the Pulmonary Circulation and the Great Blood Vessels in Man: Further Observations."

Dr. R. G. Taylor, Los Angeles, read the chairman's address, entitled "Anomalies of the Sacrolumbar Articulations."

Drs. Robert I. Walter, Arnold L. Bachman and William Harris, New York, presented a paper on "The Treatment of Carcinoma of the Ovary." Discussed by Dr. D. Y. Keith, Louisville, Ky.

Drs. Edward L. Jenkinson and Arthur F. Hunter, Chicago, presented a paper on "Bronchiogenic Carcinoma: A Diagnostic Enigma." Discussed by Drs. LeRoy Sante, St. Louis; Ross Golden, New York, and R. G. Taylor, Los Angeles.

Drs. J. Fletcher Lutz and Lewis C. Pusch, York, Pa., presented a paper on "Angio-Endothelioma of Bone." Discussed by Drs. Charles F. Geschickter, Baltimore, and John T. Murphy, Toledo, Ohio.

THURSDAY, MAY 17—AFTERNOON

The following officers were elected: chairman, Dr. Merrill C. Sosman, Boston; vice chairman, Dr. Raymond Behler, Indianapolis; secretary, Dr. John T. Murphy, Toledo, Ohio; delegate, Dr. Edward H. Skinner, Kansas City, Mo.; alternate, Dr. Eugene P. Pendergrass, Philadelphia; representative to the Board of Radiology, John W. Pierson, Baltimore.

Drs. R. Glen Spurling and F. Keith Bradford, Louisville, Ky., presented a paper on "Neurologic Aspects of Intervertebral Disk Protrusions."

Drs. W. Edward Chamberlain and Barton K. Young, Philadelphia, read a paper on "The Diagnosis of Intervertebral Disk Protrusions by Intraspinal Injection of Air."

Dr. John D. Camp, Rochester, Minn., read a paper on "The Roentgenologic Diagnosis of Intraspinal Protrusion of the Intervertebral Disks by Means of Radiopaque Oil."

Dr. J. Grafton Love, Rochester, Minn., read a paper on "Protruded Intervertebral Disks, with a Note Regarding Hypertrophy of Ligamenta Flava."

These four papers were discussed by Drs. William Jason Mixter, Boston; Claude Moore, Washington, D. C.; L. H. Garland, San Francisco, and J. Daniel Willems, Chicago.

Dr. William A. Nosik, Cleveland, co-author with Dr. B. H. Nichols, Cleveland, gave a brief outline of the paper on "Myelography with the Use of Thorium Dioxide Sol as a Contrast Medium." This paper was not read, owing to Dr. Nichols' absence.

FRIDAY, MAY 19—AFTERNOON

A joint meeting was held with the Section on Gastro-Enterology and Proctology.

The following papers were read as a symposium on "The Small Intestine: Anatomic, Roentgenologic, Pathologic and Clinical Considerations":

Dr. George W. Chamberlin, Philadelphia: "The Roentgen Anatomy of the Small Intestine."

Dr. Harry M. Weber, Rochester, Minn.: "The Roentgenologic Manifestations of the Non-Neoplastic Lesions of the Small Intestine."

Drs. David Adlersberg and Michael Weingarten, New York: "The Small Intestine in Nutritional Deficiency."

Dr. E. C. Rosenow, Rochester, Minn.: "Epidemic Enteritis: Etiology and Relation to Other Infections of the Small Intestine."

Dr. Everett D. Kiefer, Boston: "Clinical Aspects of Chronic Disorders of Small Intestine."

These five papers were discussed by Drs. Kendall A. Elsom, Philadelphia; Sara M. Jordan, Boston; Ross Golden, New York; W. Edward Chamberlain, Philadelphia; Theodore L. Althausen, San Francisco; John T. Murphy, Toledo, Ohio; George W. Chamberlin, Philadelphia; Harry M. Weber, Rochester, Minn.; David Adlersberg, New York, and Everett D. Kiefer, Boston.

SECTION ON MISCELLANEOUS TOPICS

Session on Anesthesia

WEDNESDAY, MAY 17—MORNING

The meeting was called to order by the chairman, Dr. Ralph M. Waters, Madison, Wis.

Dr. Paul W. Searles, Buffalo, read a paper on "The Effect of Certain Anesthetics on the Blood." Discussed by Dr. Charles J. Betlach, Chicago.

Dr. E. A. Rovenstine, New York, read a paper on "The Principles of Inhalation Anesthesia for Thoracic Surgery." Discussed by Drs. Joseph W. Gale, Madison, Wis., and Arno Benedict Luckhardt, Chicago.

Dr. Philip D. Woodbridge, Boston, read a paper on "Prevention of Ignition of Anesthetic Gases by Static Spark." Discussed by Drs. Everett A. Tyler, Philadelphia; Ralph M. Waters, Madison, Wis.; Arno Benedict Luckhardt, Chicago, and Prof. J. W. Horton, Boston.

Dr. Paul M. Wood, New York, read a paper on "Trichlorethanol: A Preliminary Clinical Report." Discussed by Dr. P. K. Knoefel, Louisville, Ky.

Drs. Henry S. Ruth, Merion Station, Pa., and Ralph M. Tovell, Hartford, Conn., presented a paper on "Intravenous Pentothal." Discussed by Drs. George J. Thomas, Pittsburgh, and Ralph Thomas Knight, Minneapolis.

Dr. M. H. Seevers, Madison, Wis., read a paper on "Respiratory Alkalosis During Anesthesia: An Experimental Study in Man." Discussed by Dr. Henry K. Beecher, Boston.

Dr. John H. Evans, Buffalo, read a paper on "Oxygen Tolerance versus Oxygen Dosage." Discussed by Dr. F. A. D. Alexander, Albany, N. Y.

Drs. P. P. Volpitto, R. A. Woodbury and W. F. Hamilton, Augusta, Ga., presented a paper on "Direct Arterial and Venous Pressure Measurements During Clinical Anesthesia." Discussed by Dr. John S. Lundy, Rochester, Minn.

THE SCIENTIFIC EXHIBIT

The Scientific Exhibit at the St. Louis session was characterized by the large amount of teaching material for the physician in general practice. There were 226 exhibits in all, 160 of which were presented under the auspices of the various sections, eighteen in the exhibit symposium on heart disease, and forty by state and national organizations. There were two special exhibits sponsored by the Board of Trustees, and six groups of motion pictures in connection with the various sections.

The special exhibit on anesthesia was presented for the third time under the auspices of a committee composed of Ralph M. Waters, chairman, Madison, Wis.; John S. Lundy, Rochester, Minn.; Henry S. Ruth, Philadelphia, and Philip D. Woodbridge, Boston. Demonstrations throughout the week were presented by a competent corps of anesthetists and were largely attended. A pamphlet describing the exhibit was distributed. There was a special motion picture program in an area adjoining the exhibits.

The special exhibit on fractures was presented under the auspices of a committee composed of Kellogg Speed, chairman, Chicago; Frank D. Dickson, Kansas City, Mo., and Walter Estell Lee, Philadelphia. A carefully selected group of surgeons from various parts of the country assisted with the demonstrations and a pamphlet describing the exhibit was distributed.

Other features of the St. Louis session included an exhibit symposium on heart disease in conjunction with the American Heart Association; an exhibit symposium on graduate medical education; groups of exhibits on cancer and pneumonia, and motion pictures shown under the auspices of the different sections in spaces adjoining their exhibits.

Thirty-one papers read before the various sections of the Scientific Assembly were correlated with the exhibits in the Scientific Exhibit.

The following physicians served as representatives to the Scientific Exhibit from the different sections of the Scientific Assembly:

Section on Practice of Medicine, Fred M. Smith, Iowa City.

Section on Surgery, General and Abdominal, Grover C. Penberthy, Detroit.

Section on Obstetrics and Gynecology, H. Close Hesseltine, Chicago.

Section on Ophthalmology, Georgiana Dvorak-Theobald, Oak Park, Ill.

Section on Laryngology, Otology and Rhinology, Lee Wallace Dean Jr., St. Louis.

Section on Pediatrics, Arthur F. Abt, Chicago.

Section on Pharmacology and Therapeutics, Wallace M. Yater, Washington, D. C.

Section on Pathology and Physiology, F. W. Konzelmann, Philadelphia.

Section on Nervous and Mental Diseases, Roland P. Mackay, Chicago.

Section on Dermatology and Syphilology, Hamilton Montgomery, Rochester, Minn.

Section on Preventive and Industrial Medicine and Public Health, Paul A. Davis, Akron, Ohio.

Section on Urology, R. S. Ferguson, New York.

Section on Orthopedic Surgery, F. A. Jostes, St. Louis.

Section on Gastro-Enterology and Proctology, Sara M. Jordan, Boston.

Section on Radiology, E. E. Downs (deceased), Woodbury, N. J.

REPORT OF THE COMMITTEE ON AWARDS

The Committee on Awards made the following report:

GROUP I

(Awards in Group I are made for exhibits of individual investigation, which are judged on the basis of originality and excellence of presentation.)

The GOLD MEDAL to George W. Thorn, R. Palmer Howard, Kendall Emerson Jr. and Warfield M. Firor, Johns Hopkins University and Hospital, Baltimore, for exhibit illustrating studies on desoxycorticosterone (a synthetic adrenal cortical substance).

The SILVER MEDAL to George P. Robb and Israel Steinberg, New York, for exhibit illustrating visualization of the chambers of the heart, the pulmonary circulation and the great blood vessels in man.

The BRONZE MEDAL to J. F. Fulton and Margaret A. Kennard, Yale University, New Haven, Conn., and Carlyle F. Jacobson, Washington University, St. Louis, for exhibit illustrating functions of the frontal lobe with particular reference to the motor and premotor areas (areas 4 and 6 of Brodmann).

CERTIFICATES OF MERIT, Group I, are awarded to the following (alphabetically arranged):

Graham Asher, George Walker and Frank Hoecker, University of Kansas, Kansas City, for exhibit illustrating the lag-screen electrocardiograph for the instant and continuous viewing of electrocardiograms.

Hugh R. Butt and Jesse L. Bollman, Mayo Clinic, Rochester, Minn., for exhibit illustrating vitamin K in the control of hemorrhage in jaundice.

A. Louis Dippel and Webster H. Brown, Johns Hopkins Hospital, Baltimore, for exhibit illustrating roentgen visualization of the placenta in placenta praevia and other conditions.

GROUP II

(Awards in Group II are made for exhibits which do not exemplify purely experimental studies and which are judged on the basis of excellence of presentation.)

The GOLD MEDAL to Elmer L. DeGowin, John E. Harris and E. D. Plass, State University of Iowa, University Hospitals, Iowa City, for exhibit illustrating the preservation of blood for transfusion.

The SILVER MEDAL to Philip Lewin, Chicago, for exhibit illustrating backache and sciatica.

The BRONZE MEDAL to Morris Moore, Barnard Free Skin and Cancer Hospital, St. Louis, for exhibit illustrating mycotic infections of man.

CERTIFICATES OF MERIT, Group II, are awarded to the following (alphabetically arranged):

Bert R. Boone, United States Public Health Service, Washington, D. C., for exhibit illustrating stethography in school children.

R. H. Jackson, J. W. Sisk and A. S. Jackson, Jackson Clinic, Madison, Wis., for exhibit illustrating diseases of the gallbladder ducts and liver.

Isaac Schour and H. G. Poncher, University of Illinois College of Dentistry and College of Medicine, Chicago, for exhibit illustrating calcium metabolism and teeth.

HONORABLE MENTION

In addition, the following exhibits are deemed worthy of Honorable Mention (alphabetically arranged):

Walter M. Boothby, C. W. Mayo, W. R. Lovelace II and A. H. Bulbulian, Rochester, Minn., for exhibit illustrating the use of oxygen in medicine, surgery and aviation; historical development; a new method of administration.

Robert Elman, Charles L. Hoagland, L. H. Hemplemann Jr. and Wilson G. Brown, Washington University School of Medicine, St. Louis, for exhibit illustrating acute pancreatic disease.

J. R. Lindsay, University of Chicago, Chicago, for exhibit illustrating suppuration in the petrous pyramid; pneumatization of the pyramid; histopathology of suppuration; x-ray demonstration.

Irwin Schulz, W. P. Blount, Charles Fidler, G. William Fox, Robert Montgomery, Arthur A. Schaefer, A. C. Schmidt, H. C. Schumm and Stanley J. Seeger, Milwaukee Children's Hospital, Milwaukee, for exhibit illustrating fractures in children; principles of treatment.

Bedford Shelmire and H. L. Graham, Dallas, Texas, for exhibit illustrating survey of common weeds causing contact eczema; patch testing with their oils.

SPECIAL MENTION

Special mention is made of the following exhibits (alphabetically arranged):

W. F. Braasch, J. L. Crenshaw and T. L. Pool, Mayo Foundation, Rochester, Minn., for exhibit illustrating recent advances in urologic diagnostic methods.

V. S. Counseller and J. T. Priestley, Mayo Foundation, Rochester, Minn., for exhibit illustrating surgery of the genito-urinary tract.

Elliott P. Joslin and Howard F. Root, Boston, with Louis I. Dublin and Herbert H. Marks, New York, for exhibit illustrating the current diabetes situation. (Dr. Joslin has previously received a medal in the Scientific Exhibit for his work on diabetes.)

Robert E. Schlueter and Ethel A. Washburn, St. Louis, for exhibit illustrating the medical history of St. Louis.

G. J. Thompson, E. N. Cook, J. L. Emmett, Mayo Foundation, Rochester, Minn., for exhibit illustrating transurethral surgery.

EDUCATIONAL CLASSIFICATION

A Special Certificate of Merit is awarded to the American College of Surgeons, Chicago, for its exhibit on cancer clinics.

Special Mention is made of the cooperative exhibit on pneumonia by the Northwestern University Medical School, University of Chicago Department of Medicine, and the Illinois State Department of Public Health.

SUBSIDIZED EXHIBITS

The Committee on Awards commends highly the special exhibits on anesthesia and fractures sponsored by the American Medical Association.

COMMENTS

The Committee believes that the appointment of carefully selected section exhibit representatives should be continued in order to secure proper correlation of the Scientific Exhibit with the Scientific Assembly.

It is the opinion of the Committee that the American Medical Association is greatly indebted to the Committee on Scientific Exhibit of the Board of Trustees, to the Advisory Committee, and to Dr. Thomas G. Hull, Director of the Scientific Exhibit. The Committee cannot commend too highly the arrangements, the efficient management, the stimulating instructiveness, practical as well as scientific, of the Exhibit.

LUDVIG HEKTOEN, Washington, D. C., Chairman.
VINCENT W. ARCHER, University, Va.
FRANCIS G. BLAKE, New Haven, Conn.
URBAN MAES, New Orleans.
FRED D. WEIDMAN, Philadelphia.

HOSPITALS AND MEDICAL CARE IN MISSISSIPPI

PREPARED BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The state of Mississippi was selected by the Council on Medical Education and Hospitals for a complete study of hospitals and medical facilities. The procedure involved personal visits of inspection by members of the Council's staff to all the hospitals, registered and unregistered. The state health department and a number of county health departments lent their cooperation in supplying data for the survey. The number of hospitals, related institutions and unclassified facilities inspected for the survey totaled 117.

Without exception the superintendents and medical directors gave their wholehearted cooperation. The hospital inspections consisted of examination of the staff organization, plant, equipment and clinical records, and a review of the hospital administration and finances. Statistical data were requested concerning types of service, classification of admissions, surgery, laboratory work, personnel, areas served, and so on. Individual reports were prepared for each hospital by the inspectors. These data and other material already in the Council's files form the basis for this report.

The splendid cooperation of the hospital superintendents, the state and county health departments and the Mississippi State Hospital Association is gratefully acknowledged.

METHOD OF SURVEY

The number of registered hospitals in Mississippi according to Hospital Service in the United States for 1939 was seventy-five. This publication was based on material gathered by questionnaire for the year ended Sept. 30, 1938. At that time a number of Mississippi hospitals were under consideration for registration and others have applied since.

The Mississippi survey gave the Council an opportunity to investigate first hand the hospitals under consideration for registration. The figures presented throughout this report will represent for the most part the calendar year of 1938. As twenty-three hospitals were found to be eligible for registration following the survey, the data presented in the analysis will deal with a total[1] of 100 hospitals, including those already registered and those awaiting formal action by the Council. In addition there are twenty-two ethical unclassified facilities, having a total of approximately 225 beds, which do not conform to the requirements for registration and are not included in the statistics of this survey.

TABLE 1.—*All Mississippi Hospital Facilities, 1931-1938*

Year	Hospitals	Beds	Bassinets	Patients Admitted	Average Census
1931	77	8,007	325	54,031	5,997
1932	75	8,121	320	57,367	5,967
1933	75	8,119	315	50,243	5,637
1934	76	7,934	304	49,692	5,717
1935	77	8,040	306	55,530	5,789
1936	73	8,512	323	65,079	6,102
1937	74	8,870	339	74,823	6,573
1938	100	9,337	402	76,647	7,139

It should be understood that the increase of twenty-three[1] hospitals to the present registered group does not represent an abrupt rise in hospital facilities in Mississippi during the year 1938. Applications of several hospitals have been pending for more than a year and a number of hospitals for which information had not been received for a period of years were inspected and have now agreed to supply the Council with information annually. A few small hospitals were found concerning which the Council had no knowledge whatever. With this in mind the apparent sudden rise in the number of hospitals, the number of beds, patients admitted, average census, and the like, may be properly evaluated.

1: In addition to seventy-four *registered in 1937*, one was registered in 1938; two were registered and listed following close of compilations for Hospital Service in the United States March 11, 1939. Twenty-three are recommended for registration as a result of this survey.

TABLE 2.—*General Hospital Facilities in Mississippi, 1931-1938*

Year	Hospitals	Beds	Bassinets	Patients Admitted	Average Census
1931	65	2,076	309	49,749	1,253
1932	64	2,791	308	52,224	1,146
1933	65	2,823	309	47,166	1161
1934	66	2,910	298	46,645	1,071
1935	67	2,961	304	53,007	1,205
1936	64	2,848	323	61,258	1,312
1937	63	2,818	339	70,557	1,411
1938	88	3,112	402	72,412	1,655

GROWTH OF HOSPITAL FACILITIES

The number of beds increased from 8,870 in 1937 to 9,337 in 1939, an increase of 5.3 per cent.

The hospitals investigated which were not registered but were found to be eligible included twenty-one general hospitals and two small tuberculosis hospitals, thus adding to those previously registered 234 general beds for white patients and ninety-four general beds for Negroes, or a total of 328 general beds and forty-eight tuberculosis beds.

TABLE 3.—*Hospital Facilities by Control, 1934-1938*

	Hospitals		Beds		Bassinets		Patients Admitted		Average Census	
	1934	1938	1934	1938	1934	1938	1934	1938	1934	1938
Federal	3	3	833	1,020	..	7	2,019	3,061	708	984
State	12	11	4,804	5,619	34	33	11,573	13,077	4,235	4,897
County	2	5	60	122	6	9	704	1,632	18	63
City	1	2	22	40	3	5	201	599	3	14
City-county	1	2	35	75	6	10	396	1,476	10	43
Total governmental	19	23	5,744	6,886	49	64	14,893	19,845	4,994	6,001
Church	2	2	160	213	18	24	4,387	6,305	102	118
Fraternal	1	..	12	...	..	..	50	.....	5	...
Associations and restricted corporations	17	28	795	1,111	83	154	10,609	27,566	230	563
Total nonprofit	20	30	967	1,324	101	178	15,046	33,871	337	681
Individual and partnership	27	42	811	988	113	140	13,455	19,913	261	404
Corporations (unrestricted as to profit)	10	5	412	139	41	20	6,298	3,018	125	58
Total proprietary	37	47	1,223	1,127	154	160	19,753	22,931	386	457
Total nongovernmental	57	77	2,190	2,451	255	338	34,799	56,802	723	1,138
Grand Total	76	100	7,934	9,337	304	402	49,692	76,647	5,717	7,139

Interesting is the fact that in Mississippi during the last four years there has been an average increase in beds in all types of registered hospitals of 351 a year, but the three years previous showed practically no increase in beds. Registered general hospital beds increased from 2,818 in 1937 to 3,112 in 1939; this is a total of 294, or 10.4 per cent.

The Mississippi survey undertaken early in 1939 presenting figures for the calendar year of 1938 revealed 100 hospitals registered or eligible for registration having a total of 9,337 beds, 402 bassinets, 5,698 births, 7,139 average census and 76,647 admissions.

The total number of beds increased 467, while bassinets increased sixty-three since the 1937 report; 1,679 more births were reported for 1938 than for 1937.

The figures for patients admitted and daily average census throughout this article are exclusive of the newborn and do not include outpatients. Patient days in all hospitals aggregated 2,605,735, representing a gain of 206,590 over the preceding year. Patient days in general hospitals numbered 604,075, or 23.2 per cent of the total.

The eighty-eight general hospitals admitted 72,442 patients or 94.5 per cent of the total number of admissions to all hospitals registered and eligible for registration. Since the 1937 report the average daily census increased 566. The total number of empty beds was less by ninety-nine, while at the same time the number of empty beds in general hospitals advanced fifty. The rate of occupancy in general hospitals increased from 50.1 per cent to 53.2 per cent in capacity.

Governmental hospitals numbered twenty-three, an increase of five, or 27.8 per cent, over the previous year. There were 6,886 governmental beds representing an increase of 242, or 3.6 per cent, over those reported in 1937.

TABLE 4.—*Mississippi Hospital Facilities by Type of Service*

	Hospitals	Beds	Bassinets	Patients Admitted	Average Census
General	88	3,112	402	72,442	1,655
Nervous and mental	6	5,587	...	3,237	5,133
Tuberculosis	4	543	...	479	311
Hospital departments of institutions	2	95	...	489	40
Totals	100	9,337	402	76,647	7,139

Nongovernmental hospitals increased by twenty-one, from fifty-six to seventy-seven, representing 37.5 per cent; the number of beds rose 10.1 per cent. It is noteworthy that during this period governmental beds represented 51.8 per cent of the total increase.

HOSPITALS ACCORDING TO TYPE OF SERVICE

General Hospitals.—During the last nine years the number of general hospitals has remained practically the same, rising or falling a point or two, six at the maximum, from year to year. In the past year there have been definite signs of improved and increasing hospital facilities resulting in the recommendation for registration of twenty-one general hospitals. This number, in addition to the four recently registered, increases the total general hospitals registered and recommended for registration from sixty-three in 1937 to eighty-eight in 1938. The number of general beds has increased from 2,752 in 1929 to 3,112 in 1938; bassinets in the same period have increased from 259 to 402. The total number of patients admitted in 1931 was 49,749; in 1938 general hospitals admitted 72,442, an increase of 45.6 per cent in the last seven years. The average census has increased from 1,371 in 1929 to 1,655 in 1938.

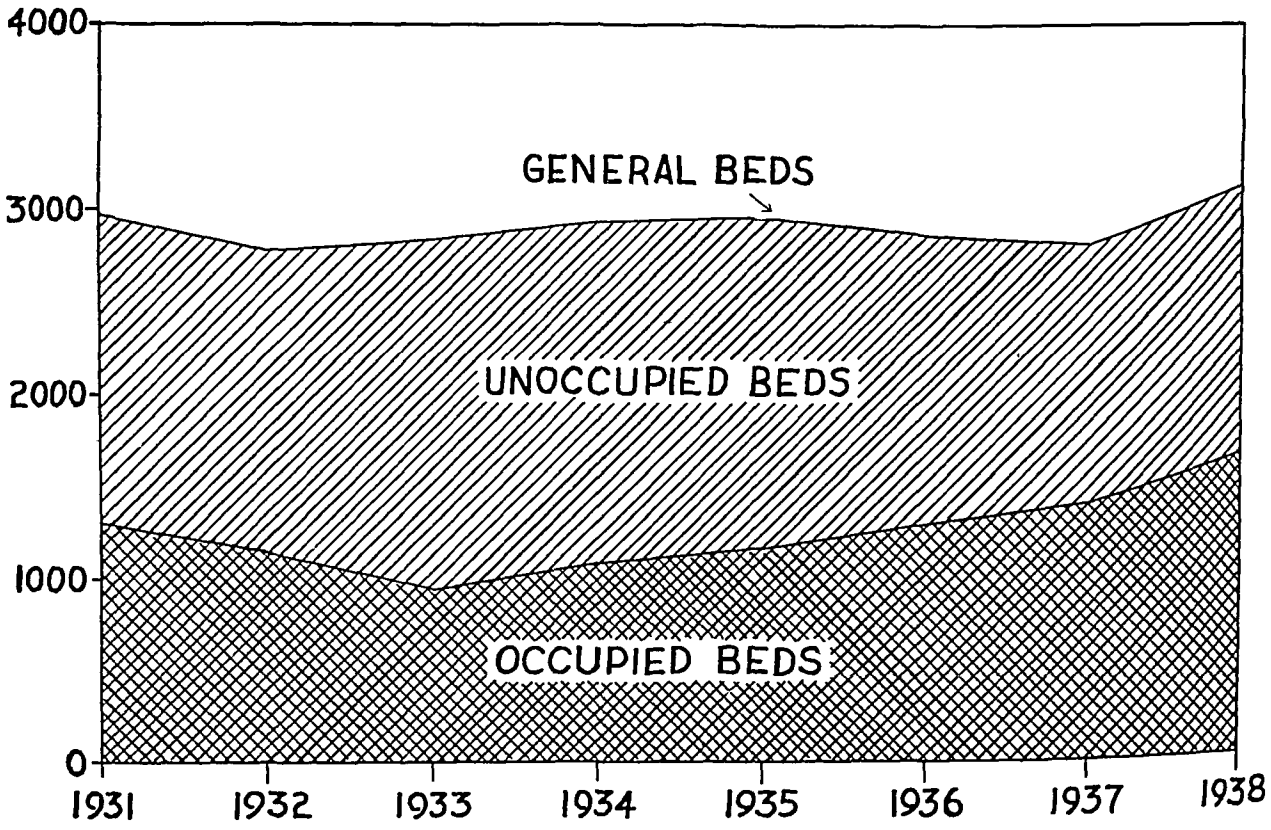

Chart 1.—General Hospital Beds in Mississippi Occupied and Unoccupied.

Hospitals were requested to break down their total admissions for the year into the number admitted to medicine, surgery, obstetrics and the various specialties, as well as designating the number of Negro patients. The response was sufficiently complete to give with the aid of the inspectors' reports the number of white and Negro patients admitted under medicine and medical specialties, surgery and surgical specialties, and obstetrics, but the number reporting on pediatrics (thirty), nervous and mental (twenty), tuberculosis (sixteen), contagion (twenty-three) and others (three) was not sufficiently complete to give an accurate picture of these services.

The specialties reported were broken down and added in their proper places under medicine and surgery. There were admitted to the medical services 19,372 white and 4,995 Negro patients, a total of 24,367. Surgical patients numbered 30,809 white and 11,230 Negro, or a total of 42,030 patients. The obstetric service admitted 5,498 white and approximately 547 Negro patients, or a total of 6,045. This gives a total of 55,670 white and 16,772 Negro or a grand total of 72,442 patients admitted to general hospitals in Mississippi in 1938.

There were reported in general hospitals 2,381 beds for white and 731 beds for Negro patients, or a total of 3,112 general beds. In 1931 there were forty-three general hospitals that accepted both white and Negro patients; today there are seventy. In 1934 there were only three registered hospitals devoted exclusively to Negro patients with a total of eighty-nine beds; today there are five registered or recommended for registration having a total of 112 beds. Thirteen hospitals are devoted exclusively to white patients. Births in general hospitals increased from 2,669 in 1934 to 5,698 in 1938, an increase of 113.5 per cent. Of the 5,698 hospital births 479 were reported as Negro births.

Two hospital departments of institutions are included on the registered list with a total of ninety-five beds, 489 patients admitted and an average daily census of forty, but are not included in the calculations for general hospitals.

Nervous and Mental Hospitals.—Nervous and mental hospitals have increased from four in 1936 to six in 1938 with a total of 5,587 beds and an average census of 5,133. The six hospitals admitted 3,237 patients. The two state mental hospitals, excluding the school for mentally deficient, have a total of 4,350 beds and 2,155 admissions divided as follows: 1,888 first admissions, 255 readmissions and twelve transfers. There was a total of 1,216 discharges and 631 deaths. The average daily census of these two hospitals is 4,035. In addition to the three state owned nervous and mental hospitals there are two individually owned and one federal hospital.

Tuberculosis Facilities.—Reports from the Mississippi State Board of Health indicate that there were 1,258 deaths from tuberculosis in 1936. In 1917, when the State Sanatorium was established, the annual rate was 2,743 but thereafter the deaths decreased continuously until 1935, when 1,199 were reported in the state. It has been estimated that approximately three fourths of the tuberculosis deaths in Mississippi occur among Negroes. This is especially significant in view of the fact that only forty beds are available at the State Sanatorium for the hospitalization of tuberculous Negroes.

The Mississippi State Tuberculosis Sanatorium has an operating capacity of 450 beds, including a fifty bed unit for preventorium service. Less than 300 beds are actually in use, however, because of lack of funds. Supplementary facilities are provided in a private sanatorium of forty-five beds and two county sanatoriums with a combined capacity of forty-eight beds. In addition there were one federal, one county, four state, one city and twenty private hospitals that reported facilities for the treatment of tuberculous patients. The sanatoriums admitted a total of 479 patients last year. Pneumothorax facilities are available at the State Sanatorium, at three of the private hospitals reporting a tuberculosis service, and in the tuberculosis clinics sponsored by the state board of health. During the biennium 1935-1937 there were eighty-seven clinics conducted in thirty-nine counties throughout the state. A total of 4,289 patients were examined, 3,013 white and 1,276 Negro.

TABLE 6.—*Mississippi Hospital Facilities Limited to Negro Patients*

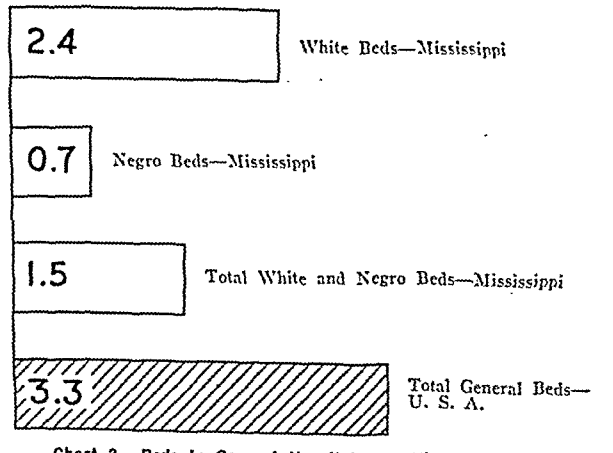
Year	Hospitals	Beds	Average Census
1931	3	65	23
1932	3	80	22
1933	3	95	11
1934	3	89	13
1935	3	40	16
1936	2	72	54
1937	2	75	35
1938	5	112	64

It is apparent that the state of Mississippi is in grave need of additional facilities for the segregation and care of both acute and chronic cases of pulmonary tuberculosis. At least twice the present number of beds are necessary to meet immediate demands. Nearly three times the present capacity would be required if a satisfactory ratio of beds to tuberculosis deaths were to be attained.

CHANGES IN HOSPITAL FACILITIES BY CONTROL

There are now twenty-three governmental hospitals registered and eligible for registration as compared with eighteen a year ago, an increase of five. The total capacity of all these governmental hospitals is 6,886.

County hospitals increased in number from two to five and beds from fifty to 122. Two city hospitals have been registered recently.



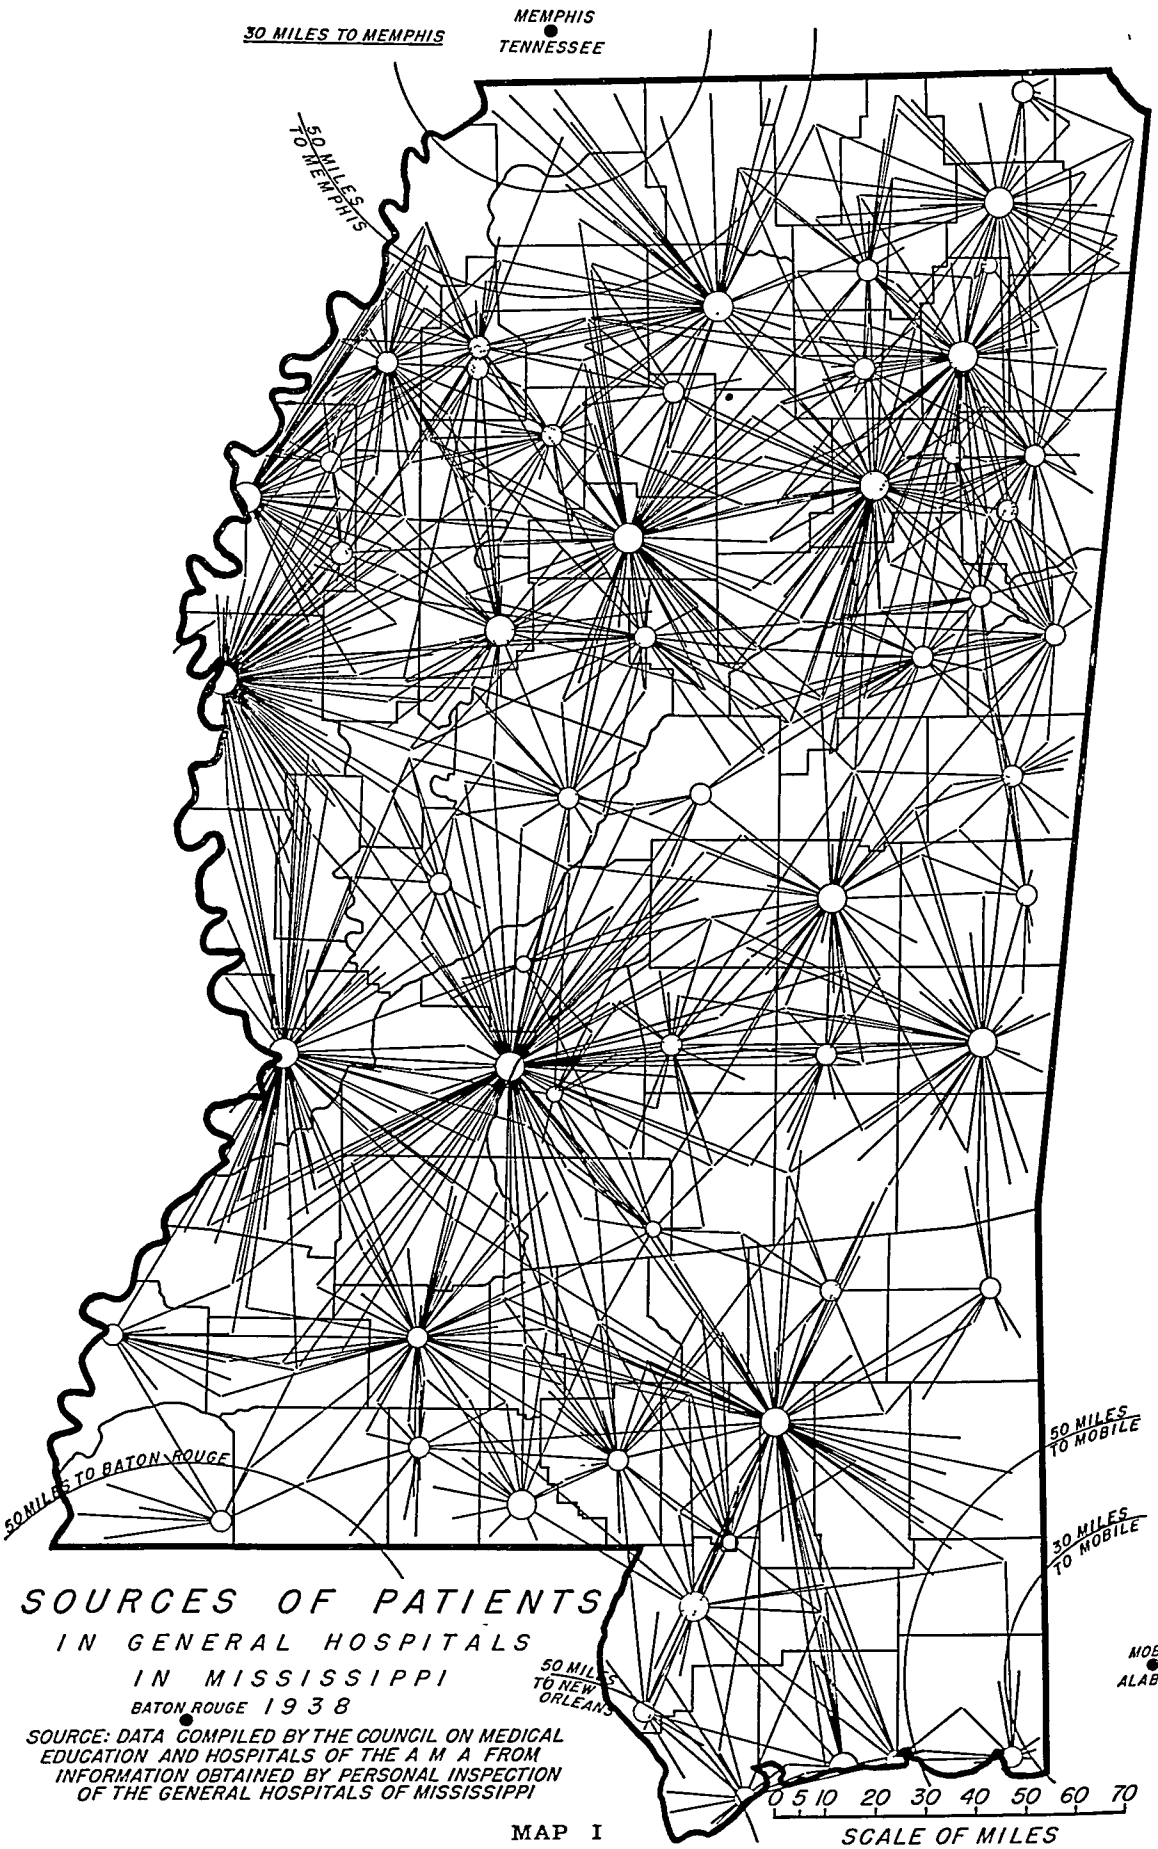


Chart 2.—Beds in General Hospitals per Thousand Population.

The returns from nongovernmental hospitals show an increase from fifty-six to seventy-seven, in beds from 2,226 to 2,451 and in bassinets from 280 to 338.

The proprietary group of hospitals number forty-seven, an increase of fourteen over the previous year. Although the proprietary hospitals are more numerous as a group, they control only 12.1 per cent of the total beds.

SOURCES OF PATIENTS

The accompanying map showing the origin of patients admitted to Mississippi hospitals in 1938 was prepared from lists furnished by each hospital. Patients whose homes were more than 70 miles from the hospital are not shown. The five state charity hospitals, the hospitals for nervous and mental

MAP I

patients and the tuberculosis sanatoriums are not included in this analysis. The map demonstrates clearly the hospital areas served regularly by each hospital center. Roads and transportation facilities throughout the state are good and apparently there is no area where the population does not have ready access to a hospital. The southeastern section reveals an area covering

TABLE 7.—*How General Hospitals Shared in Beds and Patients Admitted*

several counties where it appears patients must travel a considerable distance to a hospital. However, this area is also served by the hospitals of Mobile, 20 miles east of the border. Likewise an area in the northwestern part of the state is served to a large extent by the hospitals in Memphis, which lies 10 miles north of the state line.

The five state charity hospitals (not shown) serve the counties in which they are located and may admit patients from any part of the state. The three state hospitals for nervous and mental diseases and the state tuberculosis sanatorium admit patients from the entire state.

Approximately 25 per cent of the patients admitted to Mississippi general hospitals during 1938 came from a distance of 30 miles or more.

Total for all hospitals	72.1	71.7	74.1	76.5

OCCUPATIONS IN HOSPITAL AREAS

Sixty-five general hospitals supplied information concerning occupations of the population served. Fifty-seven hospitals reported that the greater percentage of the population from which their patients were admitted were engaged in agricultural pursuits, four reported the greater percentage in industrial occupations and only one claimed the greater percentage in commercial lines. In three instances the population was equally divided between agriculture and commercial pursuits. These percentages were estimates, as hospital records were not all sufficiently detailed to give precise information.

BED OCCUPANCY IN HOSPITALS

The average census of 7,139 patients in all hospitals for 1938 left an average of 2,198 idle beds, or 23.5 per cent. In general hospitals there were 1,457 idle beds, as compared with 1,407 the preceding year. Occupied beds in general hospitals represented 53.2 per cent of their capacity.

Nervous and mental hospitals reported the average number of empty beds decreased from 613 in 1937 to 454 in 1938. There were 232 idle beds in tuberculosis hospitals which were

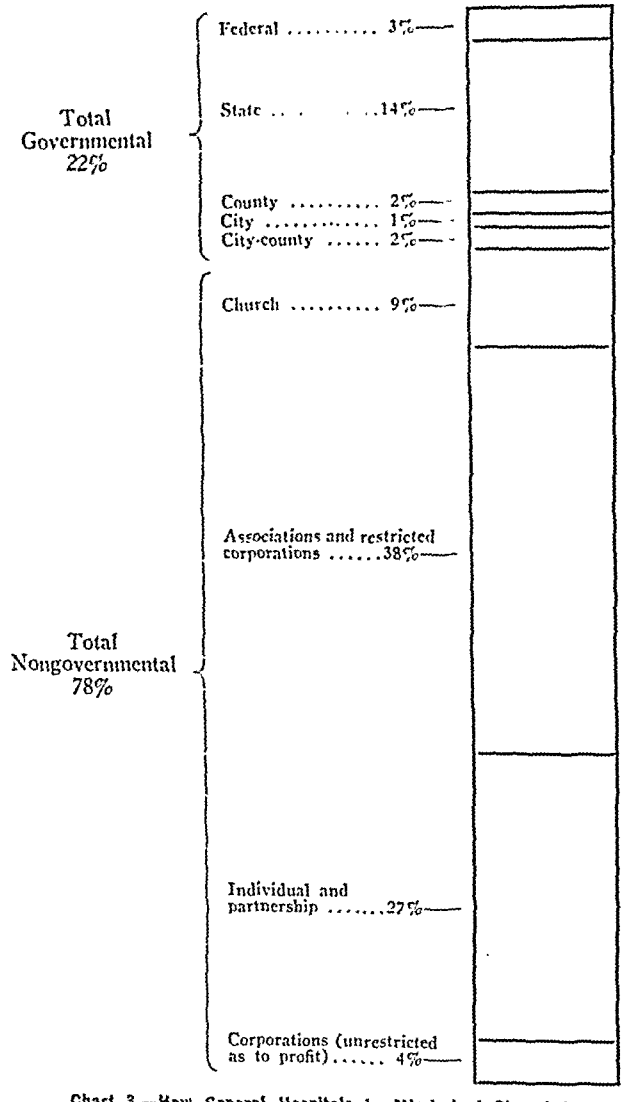

Chart 3.—How General Hospitals in Mississippi Shared in Patients Admitted.

in demand but owing to insufficient funds could not be utilized. The average number of unoccupied beds in governmental hospitals for the year was 885, a decrease of 136 over the preceding year. Occupancy of nonprofit hospitals (nongovernmental) increased from 47.4 per cent to 51.4 per cent, showing their average number of idle beds to be 643. The idle beds in all nongovernmental hospitals averaged 1,313 throughout the year.

STAFF ORGANIZATION

Relatively few of the general hospitals in Mississippi have well organized medical staffs. Forty-five have what might be considered organized staffs, as they elect officers and hold staff meetings regularly for a review of the hospital service. Since the number of general hospitals over 100 beds are few, com-

plete departmentalization is practically nonexistent. Apparently forty-three of the hospital staffs have no organization whatever. The regulation of the professional services is in the hands of the superintendent or physician owning the hospital as the case may be. Frequently the medical superintendent is the owner of the hospital and all physicians in good standing are permitted to utilize the facilities excepting the performance of major surgery.

The staff lists of 75 per cent of the hospitals of the state were examined with reference to the number of physicians on active and courtesy staffs. These hospitals claimed 699 active members and 502 courtesy staff members. Most hospitals also indicated that the facilities were open to physicians in good standing in the community.

At present there exist no approved educational programs for interns or residents in specialties in the Mississippi hospitals. Several hospitals have made application for such approval to the Council on Medical Education and Hospitals and are in the process of conforming to the requirements. Fourteen hospitals report having resident physicians. For the most part these men have had internships elsewhere and serve as general residents in order to secure additional hospital experience.

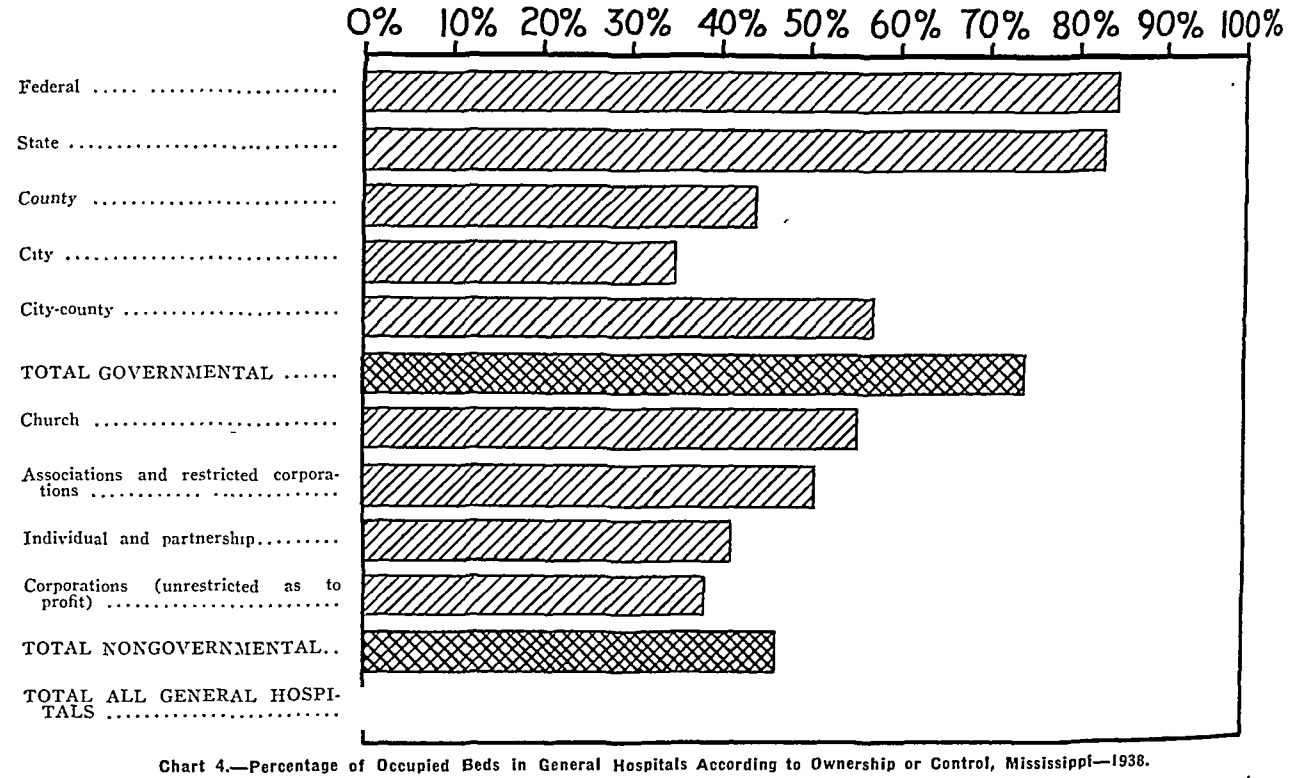

Chart 4.—Percentage of Occupied Beds in General Hospitals According to Ownership or Control, Mississippi—1938.

NURSING AND NURSING EDUCATION

Three hundred and twenty-one registered and graduate nurses were reported to be in the regular employ of eighty-eight general hospitals. These institutions also employed nineteen practical nurses. It was apparent in a number of the hospitals at the time of inspection that the lack of sufficient graduate nurses reflected in the quality of the hospital service rendered patients. For example, hospitals were examined where only one graduate nurse was employed to fulfil the duties of superintendent, supervisor of nursing and instructress to from ten to twenty student nurses.

The Mississippi State Board of Examiners of Nurses has approved thirty-six schools of nursing having a total of 710 students. Five unaccredited schools exist which reported twenty-one student nurses and ten staff registered nurses. The requirements of the nursing board state that in order to conduct a training school the hospital must have twenty-five beds and a daily average of twelve patients; high school education or its equivalent is a prerequisite for admission; the course shall be three years of continuous training; adequate equipment and facilities for classroom instruction shall be provided. The recommendations of the board concerning faculty and curriculum are in accordance with those adopted by the National League of Nursing Education.

Under the Mississippi law for the state regulation of nurses passed in 1932, certificates are issued on successful examination to nurses who are graduates of accredited schools. Nurses who are not graduates and who practiced nursing before the law took effect may be certificated as licensed attendants. Annual registration of nurses is required under the law.

The Mississippi State Board of Examiners of Nurses has not been entirely successful in the application of the standards it has adopted for schools. A number of accredited training schools are in operation which obviously fall short of the standards adopted by the board. These training schools, which are mainly in small hospitals, are being encouraged to meet the present standards, since there is need for graduates throughout the state.

The positions of hospital superintendents are held in fifty-six hospitals by physicians, in twenty-six by registered nurses and in five by lay persons. Anesthesia is administered in twenty-eight hospitals by registered nurses, in six hospitals by physicians and in five by lay anesthetists. Dietitians with some training in their field were reported on the staffs of sixteen hospitals.

CLINICAL RECORDS

Clinical records that were considered complete in all departments were found in thirty-four general hospitals. The remaining forty-seven could not be said to have satisfactory clinical records and filing indexes. It is common practice to limit the clinical chart to nurses' notes, graphic records and orders during the patient's stay in the hospital and to complete it after the patient is discharged from the hospital. A number of the hospitals allowed the charts to be placed in the permanent files without history, physical examination, progress notes, summary and final diagnosis. This condition is not peculiar to the hospitals in Mississippi and has been found in many of the smaller

hospitals throughout the country. Acceptable nomenclature of disease is used in fifteen hospitals and these institutions have full or part time record librarians, but in the majority of hospitals the superintendent or a business office employee is responsible for filing the clinical records.

DELIVERY ROOMS AND NURSERIES

Obstetric service is provided in eighty-seven of the general hospitals. Delivery rooms, separate and apart from the surgery, were found in fifty hospitals. The remaining thirty-seven utilize the surgery or deliver the patients on beds. Separate nurseries

are provided in forty-four hospitals. Nurseries are not provided in forty-three hospitals rendering obstetric service. The custom of placing the newborn infant in the mother's room exists in many hospitals.

During 1938 there was a total of 6,045 obstetric cases, and 5,698 babies were delivered in these hospitals.

RADIOLOGY DEPARTMENTS

Radiology facilities or services were reported by eighty-six general hospitals and two said they had no equipment. The scope of the radiologic service varies widely from the small portable roentgenographic apparatus to complete facilities for roentgenology including therapy. Equipment in the majority of the smaller hospitals is limited to roentgenographic work. Ten hospitals reported that registered nurses were assigned to the technical duties in the x-ray department. Thirty-one hospitals reported having thirty-three lay technicians employed. In most instances these technicians also serve the clinical laboratory.

Roentgenologic interpretations are made by the staff physicians in an overwhelming majority of the hospitals. In Mississippi there are eight physicians reporting their specialties as radiology and two are certified by the American Board of Radiology. Two hospitals reported having the services of qualified radiologists.

CLINICAL LABORATORIES

Clinical laboratory service in hospitals varies from simple routine tests to complete equipment for all types of examinations required in the general hospital. Five hospitals make no claim to laboratory facilities. Fifty hospitals stated that only routine examinations are made, not including blood chemistry or bacteriologic, serologic and tissue examinations. Thirty-three departments give more complete laboratory services within the hospital.

While many of the smaller hospitals do not have a wide scope of service in the laboratory department, clinical records demonstrate that required examinations are made by outside laboratories. Serologic tests may be referred to the state hygienic laboratory.

Examinations are made on all tissues removed in twenty-one hospitals; fifty-eight report that only selected tissues are referred to a pathologist for examination.

Six physicians serve as pathologists to the hospitals in the state. A few surgeons refer their tissues to pathologists outside the state.

Four physicians in Mississippi report their specialty as pathology or clinical pathology, and two physicians are certified by the American Board of Pathology.

Forty-eight clinical laboratory technicians were reported serving forty-two hospitals. Registered nurses with other duties serve as technicians in twelve laboratory departments.

OUTPATIENT DEPARTMENTS

Sixty-five hospitals reported that they had no outpatient department excluding the emergency service. Eighteen maintain outpatient departments and seventy-two provide emergency service. It should be borne in mind that at least thirty-six of the sixty-five hospitals without outpatient departments have doctors' offices in connection. These constitute in a sense private outpatient departments.

FIREPROOF BUILDINGS

Nineteen of the eighty-eight general hospitals in Mississippi are of fireproof construction. Two hospital plants have some fireproof buildings and others nonfireproof. Fifty-nine were considered not fireproof, although eight of these were regarded as semifireproof. It should be remembered that a great many of the smaller hospitals are one story buildings. There is a wide variation in fire fighting equipment, ranging from none at all to maximum protection including outside fire escapes.

FINANCES IN GENERAL HOSPITALS

Valuation and Indebtedness. — Eighty general hospitals reported either the real or the estimated value of their plants and equipment. Twenty-two were valued at $25,000 or less, twenty-seven between $26,000 and $50,000, nine between $51,000 and $75,000, ten between $76,000 and $100,000 and twelve at $101,000 or more.

Thirty-five reported indebtedness, either bonds or mortgage, ranging from $100 to $180,000. Thirty-five reported that they had no indebtedness other than current operating expenses. Of the thirty-two reporting specific indebtedness, twenty-one fell in the class of $25,000 or less, five between $26,000 and $50,000, two between $51,000 and $75,000, one between $76,000 and $100,000 and three $101,000 or more.

Number of Hospitals	
6	One to two dollars inclusive
20	From two to three dollars inclusive
19	From three to four dollars inclusive
20	From four to five dollars inclusive
7	From five to six dollars inclusive
4	Over six dollars
76	Number reporting
$3.83	Average cost per diem for 1938

Sources of Income.—Five state charity hospitals for general service are operated by the state. Fifty-four hospitals receive state aid in addition to their income from private patients. Sixteen of the fifty-four reported that they have additional aid from city or county or both. Two of the fifty-four have industrial contracts. Two hospitals without state aid reported city and county support and one reported contracts in addition to private patients. Twenty-four, with the exception of two that have endowments, derive their income solely from private patients; however, this figure may not be reliable, because of incomplete reporting. Three hospitals reported endowments. In addition to these the Veterans' hospital and the Indian hospital are supported by the federal government.

Physicians and Medical Service

A study of the distribution of medical personnel was made in connection with the survey of hospital facilities in Mississippi. In compiling statistical data, information was obtained

MAP II

largely from the 1938 edition of the American Medical Directory, reports of the Bureau on Medical Economics of the American Medical Association, and population studies of the U. S. Census Bureau. The Mississippi State Board of Health acts as the licensing body.

Number of Physicians.—The number of physicians in Mississippi has shown an almost continuous decline since 1909, when the first edition of the American Medical Directory was published. Prior to that time there was a decrease from 1,682 physicians in 1886 to 1,367 in 1896, but thereafter a gradual increase took place until a total of 1,749 was reached in 1906.

By 1909 the list had expanded to 2,054, but, since this period represented a transition from the Polk to the American Medical Directory, part of the increase may have been due to the difference in methods of compiling biographic data.

Only a slight reduction occurred during the next seven years, but the period 1918-1921 showed a sharp decrease from 1,975 physicians to 1,761. This change was probably a war-time adjustment, although the general decrease from 1914 to 1925 can be attributed largely to the elimination of many low grade medical schools through the activities of the American Medical Association in establishing higher standards of medical education.

In the last fifteen years the number of physicians in Mississippi has been reduced from 1,792 to 1,495. Thus the list is now at the lowest level since 1896, when 1,367 doctors were reported.

TABLE 10.—*Number of Physicians in Mississippi (1886-1938)*

Year	Number of Physicians	Population per Physician (Miss.)	Population per Physician (U. S.)
1886 Polk	1,682	673	662
1890	1,606	803	629
1893	1,465	880	650
1896	1,367	943	678
1898	1,550	832	636
1900	1,510	1,027	636
1902	1,555	998	644
1904	1,696	915	641
1906	1,749	887	637
1909 American Medical Directory	2,054	755	679
1912	2,009	895	693
1914	2,047	878	688
1916	2,048	877	694
1918	1,975	910	709
1921	1,761	1,017	744
1923	1,792	999	764
1925	1,702	1,052	781
1927	1,680	1,066	791
1929	1,633	1,097	797
1931	1,567	1,283	794
1934	1,525	1,310	784
1936	1,515	1,326	778
1938	1,495	1,353	762

According to the 1938 directory there are 1,495 physicians in Mississippi, of whom 1,307 are in private practice. Eighty-three are retired, twenty-nine devote their time principally to hospital duties, thirty-four are in government service and forty-two are engaged in other lines of professional activities. Twenty-three women physicians are included; also fifty-two Negro doctors. Reference should be made to table 10 showing the number of physicians and population ratios from 1886 to 1938.

Physicians in Relation to Population.—Since 1886 the population in Mississippi has expanded approximately 79 per cent, while the number of physicians has decreased 11 per cent. This is in marked contrast to the general population increase in the United States of 118.2 per cent between 1886 and 1934 and the increase of physicians by 84.3 per cent.

The average population per physician in the United States has varied between 629 in 1890 and 797 in 1929. The ratio in 1938 was 762.1. In Mississippi the variation is from 673 in 1886 to 1,353 in 1938. Accordingly the proportion of physicians to population is considerably lower in Mississippi than the average for the country at large.

The reduction in medical personnel is not limited to Mississippi, however, for in the period 1916-1938 there were similar decreases in other Southern states, as shown in the following tabulation:

State	Number of Physicians (1916)	Number of Physicians (1938)
Alabama	2,569	2,072
Arkansas	2,637	1,850
Georgia	3,421	2,756
Kentucky	3,584	2,762
Mississippi	2,048	1,495
Tennessee	3,457	2,917

* Population figures included in table 11 for comparative purposes are from the 1930 census, while the number of physicians is based on the 1938 American Medical Directory.

The same period showed increases, however, in North Carolina from 2,102 physicians to 2,663; Louisiana, 2,060 to 2,200; Florida, 1,321 to 2,072. Only a slight change occurred in South Carolina, 1,399 to 1,354.

In Alabama, North Dakota and South Carolina the ratio of population to physicians is considerably higher than in Mississippi, while in North Carolina it is somewhat lower.

State	Number of Physicians (1938)	Population* per Physician
Alabama	2,072	1,397
North Dakota	508	1,390
South Carolina	1,354	1,385
Mississippi	1,495	1,353
North Carolina	2,663	1,311
United States	169,628	762

* Population as estimated for 1937 by U. S. Bureau of Census.

Location of Physicians.—By reference to table 11 and map II one will note the distribution of physicians by counties and the location of medical personnel in relation to hospital facilities.

As might be expected, the heaviest concentration of medical personnel occurs in counties where the larger cities are located and where hospital facilities are readily available. Thus in 1938 we find that 325 physicians are located in towns of less than 500 population, 222 in units of 500-999, while 422 are in towns of 1,000-4,999, and 526 in cities over 5,000. The tendency of decreasing rural practice is readily apparent in the corresponding figures for 1923:

Number of Physicians	Population of Towns
667	Under 500
259	500-999
448	1,000-4,999
418	5,000-and over

There are no counties in Mississippi without medical personnel, but the number of physicians varies from two in Issaquena County to 126 in Hinds County, where the city of Jackson is located. Sixteen counties have more than 2,000 people per physician and in one the ratio exceeds 3,000:1. In considering these ratios one should take into account that medical service is not restricted by county lines and that marked improvements in roads and transportation have made medical and hospital care readily accessible. It was the general expression of doctors throughout the state that medical care is readily available to people who desire the services of a physician.

	Total	188

Special Practice.—According to the 1938 edition of the American Medical Directory there are 366 physicians in Mississippi engaged in special practice. Of these, 174 limit themselves to a particular specialty while 192 give special attention to a limited field. Twenty-nine are certified by the Specialty Boards as shown in table 12. Membership in special societies has now reached 188. Reference should be made to table 13.

County Medical Society Membership.—In Mississippi the memberships in the American Medical Association reached their highest level in 1934, when 1,218 physicians were affiliated with local county medical societies. In 1936 the membership was 1,200, but in the following two years a marked decrease occurred, since the 1938 directory lists only 945 members in Mississippi.

TABLE 13.—*Number of Physicians in Special Practice*

Specialty	Limited Specialty	Special Attention	Total Specialists	Certified by American Boards

Totals	174	192	366	29

It is of interest to note that the membership was 992 in 1909. It was 1,033 in 1916, 1,082 in 1921, 936 in 1925, and 1,067 in 1931. Thus in spite of the continual decrease in number of physicians, the percentage of county medical society memberships increased from 48.3 per cent in 1909 to 79.3 per cent in 1936, after which it dropped to 63.2 per cent in 1938.

MEDICAL EXTENSION TRAINING IN MISSISSIPPI

During the past five years the Mississippi State Medical Association and the Mississippi State Board of Health, with the material assistance of the Commonwealth Fund of New York and with the Division of Medical Extension of Tulane University of Louisiana as the executive agency, have provided the practicing physicians of Mississippi with opportunity to continue their education after licensure. A postgraduate committee of seven members has represented contributing agencies, as well as the Mississippi State Hospital Association. Subjects requested by physicians have included obstetrics, pediatrics, surgical and gynecologic diagnosis, and syphilology. Physicians paid registration fees of $3 and $5 for one or two and one-half week courses which included lectures, clinics, round table discussions and consultation services. Every section of the state has been covered; 620 physicians registered in 1935-1936 and 330 in 1936-1937; 389 have registered since 1938. By establishing from forty to forty-five teaching centers throughout the state, physicians have been brought into close personal contact with prominent medical educators who have an appreciation of the practical problems of medical care.

NEGRO PHYSICIANS

In proportion to Negro population, Mississippi has the smallest number of Negro physicians of any state in the Union. On the basis of 1930 census reports and the number of physicians listed in 1932 by the National Medical Association, the average ratio of Negroes to Negro physicians was 2,984:1 (population 11,891,143, physicians 3,985). The Southern states with a Negro population of 9,361,577 showed a ratio of 4,079:1, while the Northern states reported 1,497:1.

Mississippi with a total of 1,009,718 (1930) Negroes and only seventy-one Negro physicians has a ratio far higher than any other state, 14,221:1. The next highest ratio occurred in South Carolina, 9,562:1.[2] Alabama had 8,145:1, North Carolina 7,852:1, Louisiana 6,692:1 and Georgia 5,493:1.

The 1938 directory lists fifty-two Negro physicians in Mississippi, as compared with fifty-eight in 1936, sixty in 1934, fifty-three in 1931, thirty-five in 1925, thirty-three in 1921, forty-three in 1916 and thirty-one in 1909. Their distribution by counties is shown in table 11.

AGE OF PHYSICIANS

The 1938 directory lists 253 or 16.9 per cent of the physicians in Mississippi as having reached the age of 65. This is in marked contrast to the 8.9 per cent in 1923 when only 159 doctors in the state were classified as 65 years or over. In this connection it is of interest to note that the Bureau of Medical Economics studied a group of 71,170 physicians (1931) and found that 9,447 or 13.3 per cent were 65 years of age or more.[2] From reports obtained during the survey it would appear that various communities in Mississippi are in need of young physicians to assume the active practice gradually being relinquished by those who are now approaching the retirement age.

State Hospital Commission

A forward step in the care of the indigent sick in Mississippi was made through the efforts of the committees of the Mississippi State Medical Society and the Mississippi State Hospital Association, when in 1936 Senate Bill 223, creating the State Hospital Commission, was enacted by the legislature. An outline of the law is hereby given.

A Hospital Commission is created, composed of five members, four appointed by the governor—one from each supreme court district, one from the state at large—and the governor is the fifth member. . . .

It is made the duty of this commission to establish uniform rates for treatment of the indigent sick, within the limit of $2.50 a day for hospitalization, $7.50 for operating room and supplies for major and $2.50 for minor operations; to make rules and regulations for carrying out this purpose; to make rules and regulations for obtaining any federal funds made available for this purpose; to lay down rules setting standards to be met by hospitals qualifying to do work in treating the indigent ill; to inspect hospitals and certify the qualifications of each hospital proposing to come under the act; to supervise work of state charity hospitals; to designate certain territory to be served by state charity hospitals, and to revoke permits issued to hospitals or for hospitals. The commission is prohibited from placing in the zone of a state charity hospital a county where a qualified hospital is or shall be located.

The governor is authorized to appoint members from the county or adjoining counties to the counties in which a qualified hospital is located to serve as a board of trustees. This board is composed of three members. The board of a county owned or a municipally owned hospital shall serve as the board for this purpose. The duty of this board is to see that the benefits of this act shall apply only to persons who have been bona fide residents of the state for six months and who are unable to provide for their own care; to make monthly reports to the State Hospital Commission of the number given hospital service in their county or counties during the preceding month, and for which compensation is sought, giving the names and addresses of such patients, date of admission and discharge of each such patient, and an itemized statement of each patient's account, and send an eligibility certificate with each patient's account; to visit and inspect all hospitals in their territory, once each month, to see whether the charity patients are properly cared for, and report complaints, if meritorious, to the State Commission; to lay down necessary rules and regulations necessary to protect the patients and charity fund, and to insure an equitable distribution of the charity funds in each county and district.

The act provides for a disbursement of all per capita charity appropriations to the counties and districts on the basis of population.

In order to qualify for assistance under this act, it is necessary that a person secure a certificate of a reputable physician and two residents of good character of the county in which the applicant resides that the applicant is eligible for assistance under the act. In cases of emergency in which it is not practicable to secure a certificate before admission, the hospital may receive and care for such person and secure a certificate later.

No compensation is provided for services of members of the State Commission, and none for members of county or district boards of trustees.

Compensation to qualifying hospitals is made from a charity hospitalization fund appropriated by the legislature.

Appropriations, Biennium Beginning July 1, 1938

By House Bill No. 526, Chapter 65, Laws of Regular Session of 1938 the Legislature appropriated to the per capital part of the fund the sum of	$500,000.00
To South Mississippi Charity Hospital	57,500.00
To Matty Hersee Hospital	57,500.00
To Jackson Charity Hospital	57,500.00
To Vicksburg Charity Hospital	52,500.00
To Natchez Charity Hospital	52,500.00
Total to Charity Hospitals	$277,500.00
Grand Total to Charity Fund	$777,500.00[3]

Fifty-four hospitals, in addition to the five charity hospitals, have been approved for state aid by the commission.

Counties designated to the state charity hospitals are as follows:

Adams County to Natchez Charity Hospital, Natchez.
Hinds County to Mississippi State Charity Hospital, Jackson.
Jones County to State Charity Hospital, Laurel.
Lauderdale County to Matty Hersee Hospital, Meridian.
Warren County to Mississippi State Charity Hospital, Vicksburg.

Patients from the counties designated are required to go to the hospitals designated, but all hospitals may receive charity patients from any county in the state. During 1938 approximately 10,000 patients were treated in state charity hospitals.

Number of Patients Treated Under the State Hospital Commission

(State Aid)	
Year of 1936-1937	5,505
Year of 1937-1938	6,566
July 1, 1938, to Feb. 28, 1939	6,406

The minimum standards of the Mississippi Hospital Association have been adopted by the State Hospital Commission and are as follows:

1. All hospitals shall have modern and efficient buildings which are separate and apart from any other building and operated solely for hospital purposes.

2. Physicians and surgeons privileged to practice in the hospital shall be organized as a definite group or staff; the word "staff" to include all doctors who practice in the hospital.

3. Membership on the staff shall be restricted to physicians and surgeons who are (*a*) full graduates of medicine residing in this state, and members of their respective county medical societies and of the Mississippi State Medical Association; (*b*) competent in their respective fields, and (*c*) worthy in character and in matters of professional ethics. In this latter connection the practice of the division of fees, under any guise whatever, is prohibited.

4. The staff shall initiate and, with the approval of the governing board of the hospital, adopt rules, regulations and policies governing the professional work of the hospital; all doctors shall read and sign the rules and regulations upon election to the staff. These rules and regulations and policies shall specifically provide:

(*a*) That staff meetings be held at least once each month.

(*b*) That the staff review and analyze at the monthly staff meeting their clinical experiences in the various departments of the hospital, such as medicine, surgery, obstetrics and the other specialties; the clinical records of patients, free and pay, to be the basis of such review and analysis.

5. Accurate and complete records shall be written for all patients and filed in an accessible manner in the hospital, a case record to include at least identification data; complaint; personal and family history; history of present illness; physical examination; special examinations, such as consultations, clinical laboratory, x-ray and other examinations; provisional or working diagnosis; medical and surgical treatment; gross pathological findings; microscopic pathological findings when indicated and possible; progress notes; final diagnosis; condition on discharge; and, in case of death, autopsy findings when possible to obtain.

2. Distribution of Physicians in the United States, published by Bureau of Medical Economics of American Medical Association, May 1936.

3. Outline of the Hospital Commission Law of the Regular Legislative Session of 1936, Senate Bill No. 223, Ch. 178: Mississippi Doctor **16**: 27 (Nov.) 1938.

6. Diagnostic and therapeutic facilities under competent supervision shall be available for the study, diagnosis and treatment of patients, these to include at least (*a*) clinical laboratory and (*b*) an x-ray department.
7. At least one doctor competent in the practice of surgery and one doctor competent in the practice of internal medicine, residing in the town or city in which the hospital is located, shall be available at all times.
8. Competent nursing service shall be available at all times and the superintendent of nurses shall be a graduate nurse registered in Mississippi.
9. A physician or registered nurse trained in anesthesia shall administer all anesthetics to patients.[4]

An inspection system of the hospitals approved for care of charity patients has been developed by the commission. The secretary reports that all the hospitals have been inspected twice since the enactment of the law. Inspections consist of personal visits by the secretary or one appointed by him to examine the facilities, records and general organization. In addition, annual questionnaires giving comprehensive data concerning each hospital are required by the commission.

The Committee on Hospital Legislation of the Mississippi State Hospital Association has more recently directed efforts toward the establishment of a central state hospital unit in Jackson to care for the indigent sick in highly specialized cases which might be too expensive and in some instances impracticable to treat in the small general hospitals in Mississippi.

Mississippi State Hospital Association

The Mississippi State Hospital Association, recently incorporated, now has seventy institutional members. According to the constitution and by-laws, the purposes of the association are:

> To promote the welfare of the people of Mississippi by the furthering of efficiency and economy in the institutional care and management of hospitals and dispensaries of the state; to improve the service rendered to patients by such institutions; to secure the cooperation of other organizations with similar objects with a view to coordination of effort, and in all ways to advance the interests of all medical service institutions.
>
> To these ends, this association shall maintain such affiliations with the American Hospital Association as shall, from time to time, be mutually desirable, and shall cooperate with it in promoting common aims and purposes within this state.

Standing committees of the organization are constitution and rules, legislation and membership. Special committees are appointed for charity hospitals, mental hospitals, public and community relations, minimum standards, nursing, publications, fixed periodic payments for hospital services, hospital records, hospital staff rules and regulations, approved merchandising and hospital taxation.

The association has adopted minimum standards for hospitals and these have been adopted by the state hospital commission in determining those eligible for state aid. These minimum requirements appear in the section dealing with the state hospital commission.

The secretary of the Mississippi State Hospital Association is also secretary for the hospital commission, thus providing a good working relationship between these two agencies for the improvement of hospital service. The hospital standards adopted by the association and commission have had a wholesome effect as a compelling stimulus to hospitals in order to become members of the association and to become eligible for state aid. At the time of the inspections, conditions were found existing in hospitals on the state aid list and in the membership of the association which did not fully conform to the minimum requirements adopted. However, a steady improvement in these deficiencies is taking place.

Mississippi State Board of Health

The state department of health was established in 1908 at the request of the state medical association. It has a voice in formulating policies of the department, as it nominates members for the state board of health. This relationship has resulted in a spirit of cooperation and good will between the general medical profession and the health department.

The state board of health consists of ten members—nine appointive members and one who is elected by the state board of health to serve as executive officer and secretary. Eight of the appointive members must be regularly qualified physicians of the state and members of the state medical association. The other appointive member must be a dentist. Three medical members from each congressional district (congressional districts as of 1932) are nominated to the governor by the state medical association and three dentists from the state at large by the state dental association, from which number the governor appoints one medical member to serve from each respective district, and one dentist to serve from the state at large. These appointments must be confirmed by the senate. The term of office of each appointive member is six years. The appointments are timed so that three members are appointed every two years.

The state board of health is responsible for the activities conducted in both full time and part time county health departments. Part time health services are administered by local physicians, who are appointed by the state board of health as county health officers to serve on a part time basis, whereas full time health services are administered by physicians and other personnel who have received public health training.

The supervision of the state board of health in local programs includes: (*a*) designation of qualifications for personnel; (*b*) approval of appointments, and in full time areas salaries also; (*c*) promulgation of rules and regulations for the protection of public health throughout the state; (*d*) promulgation of rules and regulations governing program and general conduct of work of county health departments.

State wide services include registration of births and deaths, marriages and divorces; supervision of water supplies and sewerage systems; supervision of midwives; industrial hygiene service; laboratory service; and furnishing special consultative services. In all instances, however, the local health department is expected to participate in these activities and to assist the state in the performance of its duties.

Mississippi now has thirty-nine full time county health officers and part time officers in the remaining forty-three counties.

DIVISIONS OF THE STATE HEALTH DEPARTMENT

1. Division of county health work and epidemiology:
   - (*a*) County health department administration.
   - (*b*) Malaria control.
   - (*c*) Communicable disease control.
2. Division of sanitary engineering.
3. Division of maternal and child health.
4. Division of vital statistics.
5. Division of tuberculosis control.
6. State hygienic laboratory.
7. Division of industrial hygiene and factory inspection.

FULL TIME COUNTY HEALTH DEPARTMENTS

All counties of the state are empowered and required to carry out state health laws and regulations of the state board of health and to institute measures for the protection of the public health. Any county in the state may organize a full time health department; that is, a health department where all members of the personnel devote their entire time to health duties. Certain contiguous counties may jointly contribute to the organization of a district health department.

A full time county health department usually consists of the following personnel: one full time director, a public health nurse, a sanitation supervisor and a secretary. Additional personnel may be added from time to time as funds are made available.

The county health officer must have not less than one year of clinical experience in practice or a rotating internship in which three or more months are spent in pediatrics and infectious diseases. He shall have had not less than three months of special training in public health.

Under the sanitation personnel there may be a public health engineer, veterinarian, sanitation supervisor, dental hygienist, laboratory technician and clerk.

4. Mississippi Legislature, Regular Session 1936, Senate Bill 223, Section 4.

Sources of Funds.—The state board of health gives financial aid to counties operating a full time health department according to the health needs of the area, the amount of local funds available for health work, the type of organization established, and the ability of the area to continue support of the organization. The major financial responsibility for maintenance of the health department rests with the local area.

The board of supervisors is authorized by law to appropriate funds from the general county fund or in certain counties by a special tax levy. Local sources, such as cities, towns and civic clubs, may also appropriate funds for the support of the health work.

Certain trust funds from the federal government and certain nonofficial health agencies are allotted to the counties by the state board of health with the approval of the contributing agency. Outside funds are paid into the state treasury and distributed together with the state funds. For the year ended June 30, 1937, trust funds far exceeded the state appropriations. The Commonwealth Fund is by far the largest nongovernmental organization supporting the public health program. Government agencies contributing include the United States Public Health Service under the Social Security Act and the United States Maternal and Child Health Department.

PART TIME COUNTY HEALTH DEPARTMENTS

A part time county health department may be defined as a statutory division of county government with a physician in charge who gives only a part of his time to his official duties. Additional personnel may be appointed on a full time basis.

The state board of health appoints the part time county health officer who is to serve in each county. He must be a competent physician and a member of the state medical association. The salary of the part time health officer is fixed by the board of supervisors and paid from the county treasury.

Minimal duties expected of a part time health officer are: (*a*) the collection and transmitting of morbidity reports from physicians of his county; (*b*) investigation of all cases of communicable disease reportable within twenty-four hours and establishing isolation, quarantine and other control measures for it, and (*c*) otherwise to enforce all rules and regulations of the state board of health as it may direct. The health officer is responsible to the executive officer of the state board of health for the conduction of his program.

It is the policy of the state board of health to perform certain technical services of a routine nature for all part time county health departments. Programs of a special nature such as dental hygiene, immunization and maternal and infant hygiene service shall be taken up with the health officer prior to their execution. If possible, the cooperation of the health officer should be obtained in order to insure a spirit of mutual responsibility in the execution of any special program.

ACTIVITIES OF COUNTY HEALTH DEPARTMENTS

1. Law enforcement.
2. Acute communicable disease control, including immunizations.
3. Environmental sanitation.
4. Maternal hygiene.
5. Infant and preschool service.
6. School hygiene.
7. Dental hygiene.
8. Venereal disease control, including clinics.
9. Tuberculosis control, including field clinics.
10. Laboratory. The purpose of this service is to supplement all measures used by physicians in the early diagnosis and control of communicable diseases as well as to determine the safety of food and drink supplies.

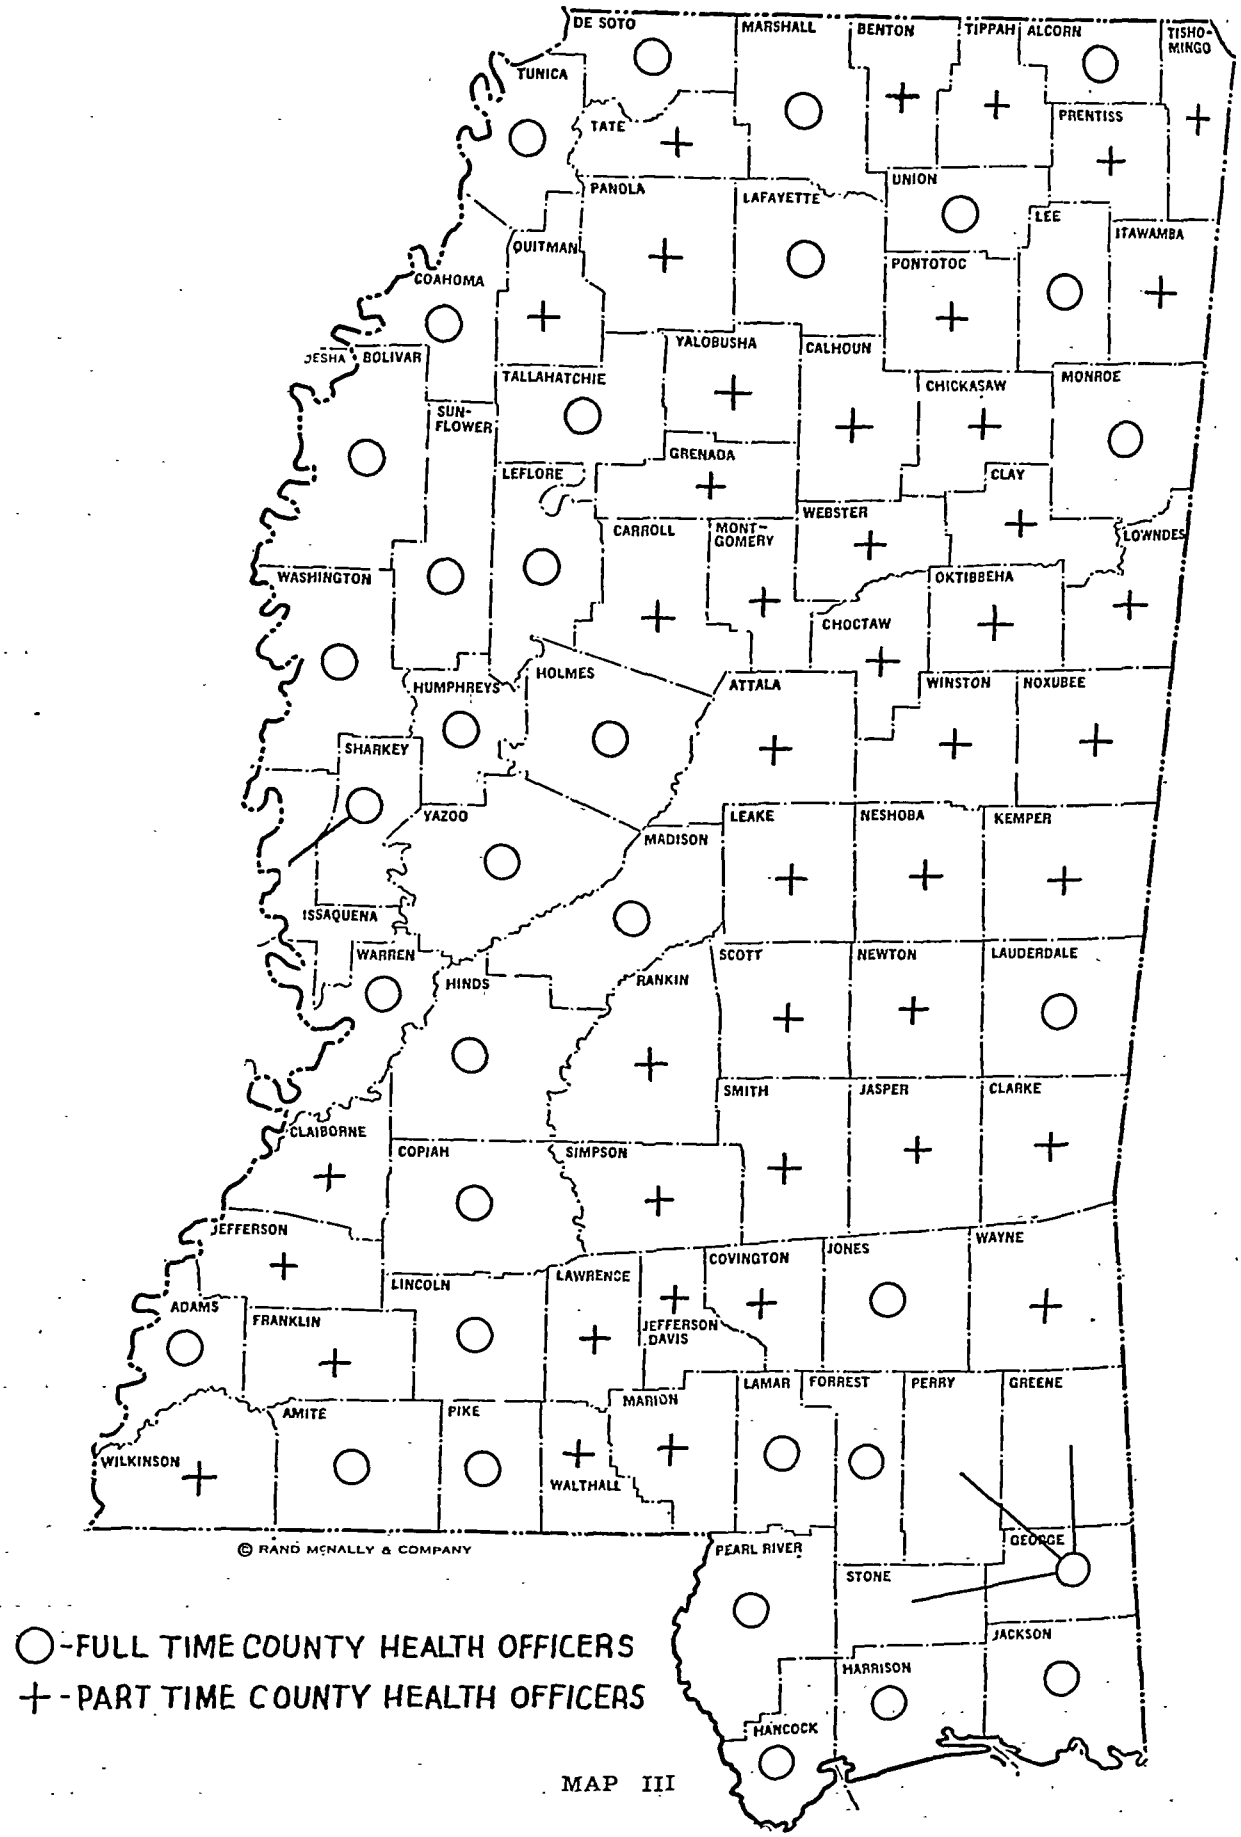
That excellent records have been made by certain county health organizations in Mississippi is attested by the places certain county health units have won in competition promulgated by the American Public Health Association in counties of nine southeastern states. In 1936 Pike County and Lauderdale County won first and second places respectively, and in 1937 Coahoma County won second place. The appraisal of the work of the county health department is based on a form prepared by the American Public Health Association.

The distribution of the full time county public health units, as well as the part time units, is shown on the accompanying map. When a full time health officer serves more than one county, district offices are established in each county.

The public health nursing service was organized in 1921. All personnel is cleared through the office of the director of public health. The duties of the public health nurses are essentially the same as those recommended by the National Organization of Public Health Nursing. Thirteen counties not having full time health officers are supplied with public health nursing service directly from the state office. Nurses are allotted to counties according to the assessed valuation for tax purposes and not according to the population.

Health education is stressed as one of the more important activities of all the full time county health departments. Newspaper publicity, radio talks, window displays and lectures to various organizations are utilized effectively. The subject matter may concern maternal health, venereal diseases, malaria, tuberculosis, communicable disease, and so on.

The service rendered by midwives throughout the state has undergone steady improvement. In 1921 there were 4,209 midwives. This number has decreased to approximately 3,000 in 1937, indicating a tendency to require the doctors' services. All but seventy-five of the midwives are Negresses. Midwives are organized into groups for the purpose of registration and instruction through the state health department. An important part of the work of the county health nurse is instruction to midwives and inspection of their equipment.



Infant and preschool clinics have been inaugurated in many counties. Defects when found are pointed out to parents, who are urged to take their children to local doctors for treatment. Public health nurses follow up each case in the homes in order to secure the best cooperation from the parents. Annual examinations of children in the first, third, fifth and seventh grades are carried on regularly in most counties.

Mississippi has established an excellent record in typhoid and malaria control. The other more common communicable diseases have been held in check by the immunization program carried out by the county health departments. The field tuberculosis service is under the supervision of the state sanatorium. Clinics are held in various sections of the state several times each year by the traveling staff of the state sanatorium. While the field work in tuberculosis is steadily improving, the facilities for hospitalization fall short of the needs. The work of the tuberculosis clinics is supplemented by home visits of the county health nurses, making possible the examination of contacts, instruction in the care of home cases, and so on.

The program for the control of syphilis is being developed; several years will be necessary to reach the maximum effectiveness. In most counties not only the patients in antepartum clinics but some groups of factory workers are examined for syphilis. Contacts of known positives are encouraged to have serologic tests.

The establishment of tuberculosis, syphilis and antepartum clinics in various counties and regions represents a definite forward step in the improvement of public health in the state.

Sanitary Engineering.—The sanitary engineer's activities concern inspection of milk and water supplies. He is in a large measure responsible for the success of the malaria control

MAP III

campaign. Much has been accomplished in recent years through the construction and improvement of drainage ditches with WPA funds. It is reported that largely through this work the number of deaths due to malaria in Mississippi has now been reduced to less than 300 a year.

Definite progress in recent years has been made in the building of sanitary privies in the rural communities and in establishing adequate sewerage control for the towns and cities. Wide use of government specifications and WPA help has been made here.

Laboratories.—Considerable variation exists in the scope of the laboratory services. Many county health units depend almost entirely on the service provided by the state hygienic laboratory where serologic tests, agglutination tests, examination of blood smears for malaria, bacterial counts on milk and water are available. Where the laboratory facilities are limited, it may be possible in some instances to improve the service by the utilization of hospital laboratory departments in the community. The state hygienic laboratory provides serologic examinations for private practitioners and hospitals throughout the state. Certain biologic products and materials for clinical tests are supplied by the department.

Veterinarians.—A few departments include part time veterinarians for inspection of animals and meat.

Dental Hygienists.—A number of county health departments employ part time dental hygienists. The work is carried on in dentists' offices, where certain days are set aside for school children. Lectures in schools and clubs serve to educate adults as well as children in the better care of teeth.

Crippled Children.—The crippled children's service operates under the department of education along with vocational rehabilitation. Most of these children are hospitalized or brought to offices of the private doctors in Jackson, Memphis and Mobile. The public health department cooperates in locating and reporting children to this department.

Medical Licensure.—The granting of license to practice medicine in Mississippi is under the jurisdiction of the state board of health. An active campaign against illegal practitioners is carried out by the state department. Since it has been difficult to secure convictions of illegal practitioners, the department leans heavily on the health educational program to improve conditions. It is interesting to note that the number of chiropractors has been reduced during the past fifteen years from 178 to forty-seven.

Vital Statistics.—A clerk is appointed in each department who in addition to the usual office routine is responsible for reporting on births, deaths and communicable diseases.

One of the tables prepared by the Division of Vital Statistics which seemed to have a bearing on the extent to which the people in Mississippi are now receiving medical care is of particular interest.

Number and Percentage of Patients Dying Without Medical Care

	White	Colored	Total Number	Total per Cent
1933.....	461	3,543	4,004	18.5
1934.....	415	3,028	3,443	15.9
1935.....	400	2,793	3,193	15.0
1936.....	479	3,056	3,535	14.6
1937.....	531	3,191	3,722	15.5

Instructions to reporting clerks exclude sudden deaths caused by cerebral hemorrhage, thrombosis, trauma, and the like.

In order to properly evaluate these figures, additional information concerning deaths reported occurring without medical care was secured by further investigation of 138 recent cases. Health officers in Lee, Chickasaw, Calhoun, Harrison, Pike, Coahoma and Monroe counties lent their assistance. Direct contact was made with the families in which the deaths occurred. The first-hand investigation of these deaths brought forth illuminating facts concerning the reliability of the records. Seventy-four of these persons actually did receive medical care, twenty-three died suddenly without medical care, nine were under the care of midwives, three had been treated by quacks, and twenty-nine did not or would not have doctors.

The latter group contains a few on which complete information was not obtained. It was learned that of these, twenty-three could have had the services of a physician, but made no request. Not one instance was found among the 138 personally investigated cases where an unsuccessful attempt had been made to secure the services of a physician, nor was there a single instance in which the doctor had refused to respond to a call.

Health officers, physicians and laymen interviewed stated that they did not know of any person who had tried to get a doctor and failed. Individuals asked if they could secure the services of a physician even though they were unable to pay most frequently answered that they could. Some persons stated that they could get the services of a physician but made no attempt because of their inability to pay. These facts would seem to point toward economic circumstances and further educational needs rather than lack of available medical service.

Farm Security Administration

The Rural Resettlement Administration, now the Farm Security Administration, early in 1936 proposed plans to enable the farm clients of the administration to provide for themselves medical services on an annual prepayment basis. According to a statement from Dr. R. C. Williams, medical director of the Farm Security Administration (Jan. 19, 1939), states with which understandings have been worked out for medical care through the Farm Security Administration total thirty (January 1939), including Mississippi. The number of counties in Mississippi in which plans are in operation total fourteen as follows:

Adams	Leflore	Smith
Amite	Madison	Sunflower
Copiah	Pike	Walthall
Jefferson Davis	Scott	Wilkinson
Leake	Simpson	

Up to January 1939, approximately fifty counties had accepted the plan.

The Farm Security Administration agrees to lend its clients a stated amount, usually between $12 and $30 per family annually, to be used for medical care. This amount is based on the abilities of the families to pay as determined by the expected net income according to the farm and home plans. Each client has the privilege of choosing any physician or druggist entering into the agreement but must confine his choice as much as possible to physicians within a reasonable distance.

The funds are placed in the hands of trustees agreed on by the physicians concerned and the Farm Security Administration supervisor in the county. Physicians render such services as in their opinion are necessary. At the end of each month physicians furnish the trustee an itemized statement of the services rendered. The funds are divided into twelve equal monthly allotments and all bills are paid on a pro rata basis. The schedule of charges for services and drugs is based on the usual charge for services furnished people of moderate means in the community. A variety of plans has been proposed by the Farm Security Administration, and the experience with these plans has shown clearly that one uniform plan cannot be operated satisfactorily for all communities which differ so widely in local conditions.

It appears to be the policy of the Farm Security Administration to provide an opportunity for the medical society to examine the administration's proposals for medical services to its clients before placing the plan in actual operation. Medical societies are warranted in studying these plans with the same sympathetic attitude that they have toward any other persons who need medical care. The actual operation of any specific administration plans will, of course, depend on the acceptance by the practicing physicians in each community in which a program is proposed. These physicians may properly look to state and county societies for an expression of acceptance or rejection of the principles involved

In Pike County the funds so lent to clients are under the trusteeship of the county medical society. Funds are divided as follows:

Medical care, ordinary drugs and incidentals 70%
Hospital care, extraordinary drugs, serums and incidentals . . 30%

Since the plan has been in operation in Pike County, the percentages of accounts paid the doctors under the pro rata scheme is as follows:

	Percentage of Accounts Paid
July, 1938	46 5
August, 1938	47 0
September, 1938	92 0
October, 1938	76 0
November, 1938	100 0
December, 1938	80 0
January, 1939	62 0
Average for Seven Months	70 5

Early in 1939 there were some 200 families under medical care through the Farm Security Administration and, according to an estimate made by the secretary of the county society, this will be increased to about 500 during the year.

The council of the state medical society considered the subject and went on record that it was opposed to state medicine or any other kind of medicine that would break the relationship of the family doctor-patient, but it also stated "In event that conditions should arise in some county where the members of organized medicine felt that the group being helped by the Farm Security Program needed better medical care, then it would be left to the members of the organized medical society in that county to work out the program." [5]

SUMMARY

During the last four years there has been a steady increase in the number of hospital beds in Mississippi. Facilities for Negroes have increased less rapidly than those for the whites

Admissions to general hospitals increased 45 6 per cent in the last seven years, while the beds increased 4 6 per cent. The occupancy in general hospitals is increasing even more rapidly than the number of beds and yet only 53 2 per cent of the general hospital beds were occupied in 1938 General hospitals admitted 94.5 per cent of all admissions for 1938, but patient days in general hospitals represented only 23.2 per cent of the total.

In appraising medical service in this state one must take into account the fact that over 50 per cent of the population in Mississippi are Negroes and that the demand for medical service among this group may fall below the requirements of the white population.

While the population is about equally divided, the number of general hospital beds for Negroes is 0 7 per thousand as compared with 2.4 per thousand of the whites. In proportion to the Negro population, Mississippi has the smallest number of Negro physicians of any state in the Union.

The geographical distribution of general hospital facilities in Mississippi may be considered adequate excepting possibly in the extreme northwest and the extreme southeast, but these areas are partially served by extrastate hospitals. Distance and transportation offer no serious difficulties in hospitalization since approximately 25 per cent of the patients admitted to general hospitals in 1938 came from a distance of thirty miles or more.

More qualified radiologists and pathologists are needed in the state. Clinical laboratory facilities do not provide a sufficiently wide scope of service in most hospitals. Investigation indicated clinical laboratory examinations should be more complete.

Obstetrical delivery rooms and nurseries are needed in many general hospitals offering this service; thirty-seven have no delivery rooms and forty-three have no nurseries.

The tuberculosis program is in need of more adequate financial support in order to utilize the present facilities and to increase the number of beds about 100 per cent

The number of beds for nervous and mental patients is apparently adequate for the needs of the state. A field psychiatric clinic program, however, is needed.

The development of nursing education in Mississippi has not kept pace with the advances in other parts of the country and this may be partially ascribed to present economic conditions The number of graduate nurses employed in general hospitals does not compare favorably with accepted standards of hospital service.

Mississippi has no hospitals approved for intern or residency training. Several have made application and are now in the process of conforming to the requirements.

It appears that the distribution of physicians in Mississippi has followed the general trend away from rural areas, but this does not necessarily mean a lack of sufficient medical service. With increased hospital facilities and modern methods of transportation and communication it is possible for individual physicians to serve larger territories. The economic factor is no doubt of paramount importance in the distribution of physicians.

Since 1886 the population in Mississippi has expanded approximately 79 per cent while the number of physicians has decreased 11 per cent. Apparently the state is finding it difficult to attract young practitioners as evidenced by the high percentage of physicians in the state over 65 years of age.

In Mississippi, as in some other Southern states, the population has increased while the number of physicians has actually decreased. It does not, however, necessarily follow that medical service is inadequate or inferior.

A state wide cooperative medical extension program has been in successful operation for five years.

The Mississippi State Board of Health with the support of private and public funds has undergone a remarkable development in recent years. At present there are thirty-nine full time county health officers and part time officers in the remaining forty-three counties.

That there is an awakening of the public and the medical profession to the value of hospital service generally is apparent in the rapid increase in the number of beds in registered hospitals and the even greater rise in occupancy during the past four years as compared with the previous period. The education of the public is also reflected in the increase in the number of births in hospitals.

All available information clearly points to the fact that existing general hospital beds are sufficient for the white population of Mississippi. Additional beds for Negroes are needed.

Extensive inquiry among all classes of the population, including doctors, health officers, nurses and workers, elicited the almost uniform response that there is practically no one in Mississippi who cannot secure medical care regardless of his ability to pay.

5 Medical Care for Clients of Farm Security Administration in Mississippi, Mississippi Doctor 16: 59 (Feb.) 1939.

OFFICIAL NOTES

ADDRESSES BY OFFICIAL STAFF

DR. W. W. BAUER:

June 9—Marquette University Testimonial Banquet for Dr. Irvin Abell, Milwaukee.
June 16—Physical Education Conference, Iowa City.
June 28—Second Health Institute at Ohio State University, Columbus, Ohio.

DR. MORRIS FISHBEIN:

June 7—University of Chicago Alumni Day Banquet, Hutchins Commons, Chicago.
June 8—Commencement address, Rochester Public Schools, Rochester, Minn.
June 18—Mount Sinai Intern Alumni Association, Chicago.
June 25—Maine Medical Association, Poland Springs, Maine.
June 29—American Pharmaceutical Manufacturers Association, Skytop, Pa.

RADIO BROADCASTS

The radio broadcasts by the American Medical Association and the National Broadcasting Company, under the title Your Health, continue as previously announced each Wednesday over the Blue network of the National Broadcasting Company at 1 p. m. eastern standard time (12 noon central standard time, 11 o'clock mountain time, 10 a. m. Pacific time).

Starting April 30, daylight saving time took effect in Chicago. The program is therefore being broadcast at the same hour Chicago daylight saving time, which means one hour earlier central standard time, two hours earlier mountain time and three hours earlier Pacific time. In communities where daylight saving time is in effect there is no change in the hour of the broadcast.

Owing to network conflicts the Chicago broadcast does not occur at 1 o'clock Wednesday but there is a rebroadcast from a recording over station WENR at 8 o'clock each Monday evening (8 o'clock Chicago daylight saving time, 7 o'clock central standard time). The program broadcast each Monday is identical with the network program of the preceding Wednesday.

The next three programs to be broadcast, together with their dates and their topics, are as follows:

June 7. Vacations—Why and How.
June 14. Never Stop Learning.
June 21. Better Babies.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Statue of James Marion Sims Dedicated.—A life size bronze statue of Dr. James Marion Sims, New York (1813-1883), pioneer gynecologist who spent his early years of practice in Alabama, was dedicated April 19 during the annual session of the Medical Association of Alabama. The statue stands on the capitol grounds near the bronze likeness of Dr. John Allan Wyeth, confederate soldier, surgeon and author and founder of the New York Polyclinic Medical School and Hospital.

ARKANSAS

Society News.—The Hot Springs Academy of Medicine was addressed April 4 by Drs. Samuel A. Thompson and Rufus B. Robins, Camden, on heart problems and head injuries respectively.——At a meeting of the Benton County Medical Society, Gravette, April 13, Drs. James T. Powell, Gravette, discussed "Cranial Trephining and Results" and Clyde L. McNeil, Rogers, "Sulfanilamide."——Dr. Barnett P. Briggs, Little Rock, addressed the Pulaski County Medical Society April 17 on "Chronic Nontuberculous Lung Infections in Children."——The Sebastian County Medical Society was addressed April 11 by Dr. Charles T. Chamberlain, Fort Smith, on "Sulfapyridine."

County Society Sponsors Postgraduate Course.—The Mississippi County Medical Society is sponsoring a postgraduate course at Osceola. The program opened April 4 and will continue for ten weeks. The staff of the University of Tennessee School of Medicine, Memphis, is offering the instruction with the assistance of the county medical society.

DISTRICT OF COLUMBIA

New Officers of District Society.—Dr. Daniel L. Borden was chosen president-elect of the Medical Society of the District of Columbia at its annual scientific assembly in Washington April 25-27. He will take office July 1, 1940, succeeding Dr. John H. Lyons, who is president-elect, and who takes office July 1 this year, succeeding Dr. William J. Mallory. Other officers include Drs. John J. Shugrue and Coursen B. Conklin, who has been secretary for twelve years, vice presidents. At the meeting the society decided to launch a program to help reduce the number of traffic deaths in Washington, approving the appointment of a committee on automobile accidents. A postgraduate course in gastro-enterology comprised the society's scientific program, with many out of state and local physicians as instructors.

Annual Psychiatric Meeting.—The second annual meeting of the Medical Society of St. Elizabeths Hospital was held in Washington April 14. The speakers included:

Dr. James M. Cunningham, Hartford, Conn., The Significance of the Structure of Langu[illegible]
Dr. Bruce B. Robinso[illegible] of the Public School in the Causation, [illegible] of the Personality Problems of Children.
Wini[illegible]ington, The Story of Psychology at St. [illegible]
Dr. [illegible] Shock Treatment and Prefrontal Lobotomy—A Comparison.
Dr. Ernest E. Hadley, Washington, Psychoanalysis and Research.
Dr. Harry Stack Sullivan, Washington, Some Notes on the Therapeutic Interview.
Dr. Nolan D. C. Lewis, New York, The Pluralistic Approach in Psychiatric Research.

Guests at the dinner were Drs. Charles Macfie Campbell, Boston, and Riley H. Guthrie; Dr. Campbell gave the annual address.

FLORIDA

Changes in Health Officers.—Dr. Rayburn N. Joyner, Marianna, has resigned as director of the Jackson County health department to enter the private practice of medicine. Dr. Charles W. McDonald, Marianna, district health officer, has been named acting health officer.——Dr. Charles M. Pearce, formerly state health commissioner of Oklahoma, has been appointed health officer of Lake County, succeeding Dr. Terry Bird. His headquarters will be in Tavares.

GEORGIA

Personal.—A bust of Dr. Emmett D. Highsmith was presented to the Fulton County Medical Society, Atlanta, recently. The bust was originally presented to Dr. Highsmith by the Georgia Power Company, with which he has been associated for many years. Dr. Highsmith is retiring from active practice on account of ill health.

District Meeting.—The First District Medical Society was recently addressed in Statesboro, among others, by Drs. Shelton P. Sanford, Savannah, on coronary thrombosis; Antonio J. Waring, Savannah, "'Chronic Cold' in Childhood," and Alfonso John Mooney Jr., Statesboro, "Atypical Signs and Symptoms in Perforated Peptic Ulcer."

State Medical Election.—Dr. Job C. Patterson, Cuthbert, was chosen president-elect of the Medical Association of Georgia at its annual convention in Atlanta April 28. Dr. William H. Myers, Savannah, was inducted as president. Vice presidents are Drs. Mark S. Dougherty Jr., Atlanta, and Amory A. Rogers, Commerce. Dr. Edgar D. Shanks, Atlanta, was reelected secretary. Savannah was chosen as the place for the 1940 session, April 23-26.

ILLINOIS

Chicago

Society News.—Dr. James B. Murphy, member of the Rockefeller Foundation for Medical Research, New York, lectured at Billings Hospital under the auspices of the Educational Association on Cancer Lectureship May 10 on "The Development of Present Trends in Cancer Research."

INDIANA

Officers of Tri-State Society.—Dr. Donald R. Brasie, Flint, Mich., was elected president of the Northern Tri-State Medical Association at its sixty-sixth annual convention at South Bend April 11, succeeding Dr. Jon N. Kelly, LaPorte. Other officers are Drs. Burt Hibbard, Lima, Ohio, vice president; E. Benjamin Gillette, Toledo, secretary, and Lyman T. Rawles, Fort Wayne, treasurer.

Society News.—At a meeting of the Indianapolis Ophthalmological and Oto-Laryngological Society March 9 Dr. Arthur W. Proetz, St. Louis, discussed "Physiology of the Nose and Its Clinical Applications."——Dr. Franklin B. Peck, Indianapolis, discussed "History of Inoculation and Vaccination Against Smallpox in the United States" before the first regular meeting of the newly organized Indiana Association of the History of Medicine May 17.——Dr. Paul L. Stier discussed "Treatment of Pneumonia with Sulfapyridine" before the Fort Wayne Medical Society April 25.——Dr. Merlen H. Draper addressed the Academy of Medicine and Surgery, Fort Wayne, April 11 on "Problems in Tuberculosis."——Dr. Marlow W. Manion, Indianapolis, was elected president of the Indiana Academy of Ophthalmology and Otolaryngology at its twenty-third annual session in Indianapolis April 5, and Dr. Edwin W. Dyar Jr., Indianapolis, secretary-treasurer.——Dr. William J. Kerr, San Francisco, discussed "Early Diagnosis of Coronary Disease" before the Indianapolis Medical Society May 11.

IOWA

State Medical Election.—Dr. Frank P. McNamara, Dubuque, was chosen president-elect of the Iowa State Medical Society at its annual meeting in Des Moines April 27 and Dr. Felix A. Hennessy, Calmar, was installed as president. Other officers of the society include Drs. Edwin A. Moore, Harlan, and Fred M. Smith, Iowa City, vice presidents; Robert L. Parker, Des Moines, secretary, and Harold J. McCoy, Des Moines, treasurer. The 1940 session will be in Des Moines May 8-10.

KANSAS

Personal.—Dr. Darrel L. Evans, Manhattan, recently resigned as health officer of Riley County.——Dr. Percy A. Petitt, Paola, has been appointed health officer of Miami County.

The Porter Lectureship in Medicine.—Homer W. Smith, Sc.D., professor of physiology, New York University, New York, gave the ninth course of lectures under the Porter lectureship in medicine, April 18-19, in Kansas City and Lawrence. His subjects were "Newer Methods of Study of Renal Function in Man"; "Evolution of the Kidney," and "Physiological Control of Renal Blood Flow."

LOUISIANA

Personal.—The Order of the Crown of Yugoslavia was recently conferred on Dr. Daniel M. Kingsley, New Orleans, for assistance given the master and crew of the Yugoslavian Steamship *Prince Andrej* who suffered from influenza while at sea.

Special Society Elections.—Dr. Henry B. Alsobrook was chosen president of the Louisiana Obstetrical and Gynecological Society recently; Dr. Paul J. Carter, vice president, and Dr. Earl C. Smith, secretary-treasurer.——At the annual meeting of the Louisiana State Pediatric Society recently in Alexandria, Dr. Philip C. De Verges was elected president; Dr. Ralph Talbot, vice president, and Dr. William C. Rivenbark, secretary-treasurer.

MARYLAND

Society News.—A symposium on bronchiectasis was presented before the Maryland Thoracic Society April 19 with the following speakers: Drs. Carroll Gardner Warner, Baltimore, Hugh J. J. Welch, Mount Wilson, Howard E. Ashbury, Waitman F. Zinn and William F. Rienhoff Jr., Baltimore.

MASSACHUSETTS

Society News.—Dr. Richard Cannon Eley, Boston, was chosen president of the New England Pediatric Society at its meeting recently; Dr. Robert M. Lord, Providence, R. I., vice president, and Dr. James Marvin Baty, Boston, secretary-treasurer.——Frank G. Young, Ph.D., research associate, National Institute for Medical Research, London, lectured at Harvard Medical School April 20 on "The Anterior Pituitary Gland and Carbohydrate Metabolism."——Dr. Ira I. Kaplan, New York, discussed "The Relation of Irradiation to Medicine" before the Greater Boston Medical Society, April 12.

State Medical Meeting in Worcester.—The Massachusetts Medical Society will hold its one hundred and fifty-eighth annual session in the Municipal Memorial Auditorium and the Hotel Bancroft, Worcester, June 6-8, under the presidency of Dr. Channing Frothingham, Boston. Among others, the following will speak:

Dr. William P. Murphy, Boston, Importance of Hypochromic Anemia.
Dr. Alexander M. Burgess, Providence, R. I., Role of Oxygen in the Treatment of Pneumonia.
Dr. Michael E. Murray Jr., Boston, Atypical Pneumonia of Unknown or Possibly Virus Etiology.
Dr. Paul A. O'Leary, Rochester, Minn., Latency and Wassermann-Fastness.
Dr. Clarence Guy Lane, Boston, Indications and Contraindications of Roentgen Rays in Dermatology.
Dr. Francis C. McDonald, Stoneham and Boston, Nonspecific Therapy.
Drs. Edward C. Curnen Jr. and John A. V. Davis, both of Boston, Specific Therapy.
Dr. John S. Coulter, Chicago, Physical Therapy in the Treatment of Fractures.
Dr. Arthur U. Desjardins, Rochester, Minn., Value of X-Ray in the Treatment of Infections and Inflammatory Conditions.
Dr. Richard B. Cattell, Boston, Obstructing Lesions of the Large Bowel.
Dr. Arthur M. Fishberg, New York, Cardiac and Circulatory Failure.
Dr. Walter C. Alvarez, Rochester, Minn., Management of the Nervous Patient.
Dr. Emil Novak, Baltimore, Endocrines and Endocrine Therapy in Gynecology.
Dr. Raymond S. Titus, Boston, A Résumé of Maternal Mortality Study in the State of Massachusetts for the Year 1938.
Dr. Frederick J. Lynch, Boston, Rupture of the Uterus.
Dr. Benjamin F. Cornwall, Salem, Obstetrical Analgesia.

Dr. Wilder G. Penfield, Montreal, will deliver the Shattuck Lecture Tuesday evening on "Epilepsy and the Cerebral Lesions of Birth and Infancy" and Dr. Elliott P. Joslin, Boston, the Annual Discourse Thursday afternoon on "The Massachusetts Medical Society and Socialized Medicine." A symposium on surgery of the stomach and duodenum will be presented Thursday morning by Drs. Chester M. Jones, Edward B. Benedict, Arthur W. Allen and Frank H. Lahey, all of Boston, and William J. Elliott, Worcester.

MICHIGAN

Changes in Health Officers.—Dr. John K. Altland, Allegan, has been appointed director of the newly created health unit in Traverse County.——Dr. Philip E. M. Bourland, Iron Mountain, has resigned as director of the Dickinson County health unit.

Obstetric Society Alters Name.—At a meeting of the Detroit Obstetrical and Gynecological Society in Detroit May 3 the society's name was changed to the Michigan Society of Obstetricians and Gynecologists. Newly chosen officers are Drs. Harry M. Nelson, president; Russell W. Alles, vice president; Howard C. Walser, secretary, and Milton A. Darling, treasurer.

Society News.—At a joint session of the Detroit Bar Association and the Wayne County Medical Society April 17 the speakers were Judge Guy A. Miller, Wayne circuit court, on "Insanity as Ground for Divorce"; William Henry Gallagher, LL.B., "Mental Capacity Necessary to Execute Wills and Other Legal Documents," and Drs. Arthur W. Frisch, Detroit, and Martin H. Hoffmann, Eloise, on "Medical-Legal Aspects of Blood Grouping" and "Insanity as a Defense" respectively.——The Michigan Society for Mental Hygiene held its third annual spring conference in Grand Rapids April 20-22; general sessions were given over to discussions of "Mental Hygiene Values in Foster Home Placements and Adoptions"; "Reality of Education in Present Day Life"; "Parental Influence in the Prevention of Crime." Among the speakers was Dr. Gregory Zilboorg, New York, on "Influence of Present Day Life on Our Children."

MINNESOTA

Sentenced for Forging Medical Prescriptions.—Harry C. Nagler, former Minneapolis pharmacist, was sentenced April 27 in the district court of Hennepin County to a prison term not to exceed five years. Nagler pleaded guilty March 27 to an information charging him with the crime of forgery in the second degree. He had forged a medical prescription using the name of "J. A. Ready, M.D." He had also forged several thousand medical prescriptions calling for whisky, alcohol and other intoxicating liquor. Eleven of the druggists, the owners of the drugstores where Nagler sold the prescriptions for sums ranging from 5 to 15 cents per prescriptions, were fined $100 each or sentenced to serve sixty days in the Minneapolis workhouse; the fines were paid. The liquor permits of these eleven stores, all expiring April 30, were not to be renewed, it was stated.

MISSISSIPPI

Society News.—The Delta Medical Society devoted its meeting in Greenville April 12 to a discussion of "What the Present Trend Toward Socialized Medicine Is Going to Do to the General Practitioner." The speakers included Drs. Ira B. Bright, and George Y. Gillespie Jr., Greenwood; Joseph G. Peeler, Shaw; Oscar E. Ringold, Cleveland; Onnie P. Myers, Indianola; James R. Jackson, Belzoni; James W. Jackson, Belzoni, and Earl T. White and Hugh A. Gamble, Greenville.

Changes in Health Officers.—Dr. James A. Sproles Jr., formerly of Jackson, has been appointed health officer of Amite County. Dr. Charles E. Catchings, Woodville, was recently named health officer of Wilkinson County to fill the unexpired term of Dr. Edwin M. Butler, Centerville, who has been appointed health officer of Union County. Dr. John W. Dorman, Holly Springs, recently was placed in charge of the Marshall County health department, succeeding Dr. Guy R. Post, who went to Clarksdale.

MISSOURI

New Committee on Industrial Health.—At the annual session of the Missouri State Medical Association, April 10-12, the following physicians were appointed to the new committee on industrial health: Drs. Edwin C. Funsch, St. Louis, chairman; John E. Castles, Kansas City; William M. Kinney, Joplin; Hyman I. Spector, St. Louis, and Gaylord T. Bloomer, St. Joseph.

Pathological Society Organized.—The St. Louis Pathological Society was recently formed with Dr. Margaret G. Smith, president; Dr. Henry Pinkerton, vice president in charge of programs, and Dr. Hollis N. Allen, secretary-treasurer. The first scientific session was to be held April 28 with the following speakers, among others: Dr. Henry W. Edmonds, malformations of the heart, and Dr. Louis H. Hempelmann Jr., a technic for differentiating mucoid material of epithelial and connective tissue origin with special reference to mixed tumors of the salivary glands.

Society News.—Dr. John S. Coulter, Chicago, discussed "The Application of Heat and Cold in the General Practice of Medicine" before the St. Louis Medical Society May 2. Dr. Forest H. Staley was the leader in the round table discussion of the society June 2; the theme was "The Present Rationale in the Treatment of Poisonous Bites." Dr. Horton R. Casparis, Nashville, Tenn., discussed "The Physicians' Responsibility in the Tuberculosis Control Problem" before the society April 18.——Dr. Nelson W. Barker, Rochester, Minn., addressed the Kansas City Academy of Medicine April 14 on "Recent Advances in Our Knowledge of Vascular Diseases."

NEW HAMPSHIRE

State Medical Meeting.—The one hundred and forty-eighth annual meeting of the New Hampshire Medical Society will be held June 8-9 at the Hotel Carpenter, Manchester, under the presidency of Dr. Clarence O. Coburn, Manchester. There will be round table conferences on medicine, surgery, pediatrics, obstetrics, diseases of the eye, birth control, anesthesia and diseases of the nose and throat. The program announces the following papers:

Dr. William G. Lennox, Boston, Treatment of Epilepsy and Migraine.
Dr. Hiram H. Merritt, Boston, Neurosyphilis and Its Treatment.
Dr. Tracy J. Putnam, Boston, Treatment of Paralysis Agitans and Athetosis.
Dr. Louis A. Buie, Rochester, Minn., Proctologic Problems of the General Practitioner and the Surgeon.
George A. Moulton, Pharm.D., Peterborough, The Development of Socialized Pharmacy in the United States.
Dr. William Wayne Babcock, Philadelphia, Clinical Phases of General Surgery.
Dr. Raymond A. Vonderlehr, Washington, D. C., Control of Syphilis.

Dr. Rock Sleyster, Wauwatosa, Wis., President of the American Medical Association, will deliver an address Friday morning on "Medical Problems of the Day" and will also speak at the banquet Friday evening.

NEW JERSEY

Public Health Week.—The Bergen County Medical Society sponsored a public health week beginning May 14 in cooperation with public health groups. Exhibits were shown at various hospitals. A meeting was held under the auspices of the woman's auxiliary to the county society in Hackensack Friday May 19 with Dr. Haven Emerson, New York, as the speaker on "Organized Care of the Sick and Public Health in Relation to 'Socialized Medicine.'" Saturday May 20 the motion picture "The Birth of a Baby" was shown in Hackensack to invited groups. The week concluded with the dedication of an "orthopedic pool" at the Bergen County Hospital, presented by the American Legion Sunday May 21.

State Medical Meeting at Atlantic City.—The one hundred and seventy-third annual meeting of the Medical Society of New Jersey will be held at Haddon Hall, Atlantic City, June 5-8 under the presidency of Dr. William J. Carrington, Atlantic City. A general public session will be held Tuesday evening June 6 with the following speakers:

Dr. Rock Sleyster, Wauwatosa, Wis., President, American Medical Association, Medical Problems of the Day.
Dr. Nathan B. Van Etten, New York, President-Elect, American Medical Association, The Doctor at the Crossroads.
Dr. Haven Emerson, New York, Governmental Planning for Health.

Among guest speakers who will address the sections are the following:

Dr. Franklin F. Snyder, Chicago, Fetal Respiration and Its Relation to Asphyxia and Pneumonia of the Newborn.
Dr. Ralph M. Tyson, Philadelphia, Cyanosis of the Newborn.
Dr. Alfred A. Strauss, Chicago, Radical Versus Conservative Surgical Procedures for Peptic Ulcer.
Dr. Yale Kneeland Jr., New York, Common Colds.
Dr. Bayard T. Horton, Rochester, Minn., Vasomotor Regulation of the Temperature of the Extremities in Health and Disease.
Dr. George P. Muller, Philadelphia, The Acute Appendicitis Problem from the Surgical Standpoint.
Dr. Martin Cohen, New York, Differential Diagnosis of Fundus Lesions Associated with Hypertensive Vascular Disease.
Dr. William Osler Abbott, Philadelphia, Treatment of Intestinal Obstruction with the Double-Barreled Intestinal Tube.
Dr. Bronson Crothers, Boston, The Pediatrician's Responsibility for the Supervision of Behavior in Children.
Dr. George G. Ornstein, New York, Pathologic Physiology of Diseases of the Lung.

The annual dinner dance in honor of the president will be held Wednesday evening June 7. The Woman's Auxiliary will have its meeting June 6-8, offering as a special feature an art, hobby and medical history exhibit.

NEW MEXICO

Personal.—Dr. John W. Myers, Albuquerque, has been appointed superintendent of the New Mexico State Hospital at Las Vegas.

Society News.—Drs. John C. Mitchell and Randolph E. Watts, Silver City, addressed the Grant County Medical Society at a meeting at Fort Bayard, March 30, on streptococcic infection and pneumonia, respectively.

NEW YORK

Pharyngitis Traced to Raw Milk.—An outbreak of streptococcic pharyngitis in Saugerties and several adjoining villages was traced to raw milk produced by one cow. The outbreak was discovered May 5 among school children in Malden and reached 502 cases before the cow was found and killed May 16. Three persons of advanced years died of the infection. The peak of the epidemic was reached on the day that the milk supply was ordered pasteurized and declined rapidly after that.

New York City

New Laboratories for DeLamar Institute of Public Health.—The new laboratories and classrooms of the DeLamar Institute of Public Health of Columbia University will occupy the top three floors of the seven story city health and teaching center nearing completion at the Presbyterian-Columbia Medical Center, 168th Street and Broadway, according to *Science*. The building has been erected through an agreement by the Presbyterian Hospital, the trustees of the university and the department of health of the city of New York. Its facilities will enable medical students at Columbia to receive practical training in public health similar to that which they receive in medicine. The laboratories and courses will also be open to physicians, dentists, nurses and graduate students. The first four floors of the building will be used by the city as headquarters for maternal care, child welfare, nursing and other public health services. The laboratories and research rooms will be so equipped that they may be used for any field of research in public health. A model classroom is situated in the southeast corner of the seventh floor. Besides being used for lectures, the room will provide opportunity for research on procedures necessary to protect the health of school children. The fifth floor will contain a laboratory designed specifically for research into diseases caused by industrial occupations and a statistical office in which a complete record of the number, kinds and occurrences of various diseases may be kept. The general laboratory for the students and research workers will be kept on the sixth floor. The seventh floor will also house an air laboratory equipped for the study of the various sources of contamination of air in public places. A

bacteriologic laboratory on the same floor will contain all the modern equipment necessary for the study of bacteriology. The offices of Dr. Haven Emerson, executive officer of the institute, and his staff will be connected with individual laboratories completely equipped with chemical, physical and bacteriologic facilities for private research. There will also be a library, a student lounge and staff accommodations. The ground floor will contain an auditorium and exhibit hall where public health education will be carried on under the direction of the institute and of the department of health.

Dr. Stockard Dies.—Charles Rupert Stockard, Ph.D., since 1911 professor of anatomy, Cornell University Medical College, died April 7 in the Hospital of the Rockefeller Institute for Medical Research of heart disease, aged 60. A native of Mississippi, Dr. Stockard graduated from Mississippi Agricultural and Mechanical College in 1899 and took his master's degree there in 1901. In 1906 he received the degree of doctor of philosophy at Columbia University. He joined the faculty of Cornell in 1906 as assistant in embryology and histology, became instructor in comparative morphology in 1908, assistant professor of embryology and experimental morphology in 1909 and professor of anatomy in 1911. In 1922 he received a medical degree from the University of Wurzburg, Germany. In 1926 he was elected to the board of scientific directors of the Rockefeller Institute and was president of the board at the time of his death. He was a trustee of the Marine Biological Laboratory, Woods Hole, Mass., the Long Island Biological Association, Cold Spring Harbor, N. Y., and the Bermuda Station for Biological Research. Dr. Stockard was managing editor of the *American Journal of Anatomy*, editor of the *Journal of Experimental Zoology* and *American Anatomical Memoirs*. In addition, he was the author of "The Origin of Blood," "Hormones and Structural Development" and "The Physical Basis of Personality," as well as of numerous contributions to scientific journals. He had served as a vice president of the American Association for the Advancement of Science, president and secretary of the American Association of Anatomists and president of the American Society of Zoologists and was a member of the National Academy of Sciences, the American Philosophical Society and the Society for Experimental Medicine and Biology. He delivered a DeLamar lecture at Johns Hopkins University, Baltimore; the Harrington Lecture, University of Buffalo; the Beaumont Lectures, Detroit; the Lane Lectures at Stanford University, Calif., and the Potter Lecture at Jefferson Medical College, Philadelphia.

OREGON

Personal.—Dr. Archie K. Higgs, Portland, was chosen by the central democratic committee of Multnomah County to succeed the late state senator George T. Eayrs.——Dr. Edward J. Dehne, Kellogg, Idaho, has been appointed health officer of Clatsop County, succeeding Dr. Lenor S. Goerke, Astoria, who has been appointed health officer of Yamhill County.

Society News.—A symposium on abortion sponsored by the Portland Academy of Obstetrics and Gynecology was presented before the Multnomah County Medical Society, Portland, April 5 by Drs. Albert Mathieu, William M. Wilson, Virgil E. Dudman and Howard C. Stearns. The Portland Academy of Pediatrics presented the program March 1 on "Acute Rheumatic Fever and Allied Disorders in Childhood," with the following speakers: Drs. Carl G. Ashley, William F. Patrick, Morris L. Bridgeman and Scott H. Goodnight.

PENNSYLVANIA

Society News.—Dr. Emil Novak, Baltimore, was the guest speaker before the Dauphin County Medical Society, Harrisburg, May 2 on "Female Sex Hormones."——Dr. Edward L. Bortz, Philadelphia, addressed the Harrisburg Academy of Medicine May 16 on "Diabetes and Other Nutritional Diseases."——Dr. Robert L. Hickok, Scranton, was recently elected full time business manager of the bulletin of the Lackawanna County Medical Society.——Medical and surgical clinics were conducted by Drs. William J. Fetter, assistant professor of medicine, and John P. Griffith, professor and chairman of the department of surgery, University of Pittsburgh School of Medicine, at a meeting of the Cambria County Medical Society, Johnstown, May 11.——The annual clinic of the Westmoreland County Medical Society was held at Torrance State Hospital, Torrance, May 12, with Drs. Emil Novak, associate professor of obstetrics, and Maurice C. Pincoffs, professor of medicine, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, as guests.

Philadelphia

Personal.—Dr. Wilmer Krusen, formerly director of public health of Philadelphia, was recently reelected president of the Philadelphia College of Pharmacy and Science for the thirteenth time.——Dr. Richard Weissenberg, formerly professor extraordinarius of anatomy, University of Berlin, and during 1937 visiting professor of cytology, Washington University School of Medicine, St. Louis, has been appointed a member of the Wistar Institute of Anatomy and Biology.——Dr. Arthur C. Morgan was honored recently at a testimonial dinner by the executive committee of the Medical Alumni Association of the old Medico-Chirurgical College, the last class of which was graduated in 1916. Dr. Morgan received a book of resolutions containing 706 signatures of alumni of the college. Dr. Charles Howard Moore, president of the association, made the presentation.

Society News.—Drs. Max B. Lurie and John Paterson, among others, addressed the Laennec Society of Philadelphia, April 25, on "Inherited Resistance in Experimental Tuberculosis" and "Pulmonary Tuberculosis in Married Couples" respectively.——Drs. Paul Sloane and James S. Dean addressed the Philadelphia Neurological Society April 28 on "Radicular Syndrome Associated with Mediastinal Tumors" and "The Cerebrospinal Fluid Protein" respectively.——At a meeting of the Philadelphia Academy of Surgery May 1 the speakers were Drs. DeForest P. Willard and Jesse T. Nicholson, on "Fracture-Dislocations of the Odontoid and First Cervical Vertebra"; Drs. Joseph R. Elkinton and Monroe T. Gilmour and W. A. Wolff, Ph.D., on "Physiochemical Determinations in the Management of Surgical Patients."——Dr. Claude S. Beck, Cleveland, delivered a Mary Scott Newbold Lecture before the College of Physicians of Philadelphia April 5 on "The Surgical Approach to Diseases of the Heart."——Dr. Chevalier Jackson addressed the Philadelphia Pediatric Society April 11 on "Acute Tracheobronchitis."——Dr. Esmond R. Long addressed the Pathological Society of Philadelphia April 14 on "The Accepted and the Disputed in the Pathology of Pulmonary Tuberculosis."

RHODE ISLAND

State Medical Meeting in Providence.—The one hundred and twenty-eighth annual meeting of the Rhode Island Medical Society will be held in Providence June 7-8 under the presidency of Dr. Edward S. Brackett, Providence. Mornings will be devoted to clinics and demonstrations at the Charles V. Chapin, St. Joseph's, Rhode Island and Miriam hospitals and afternoons to programs at the Rhode Island Medical Library. Speakers will be:

Dr. Marshall N. Fulton, Boston, Aneurysm and Rupture of the Ventricle of the Heart.
Edgar Allen, Ph.D., New Haven, Conn., Evidence from Experiments with Ovarian Hormones in Monkeys and Applications to Conditions in Women.
William C. Young, Ph.D., Providence, Ovum and Spermatozoon Age at the Time of Fertilization and the Course of Gestation and Development in Lower Animals.
Dr. Arthur T. Hertig, Boston, Pathologic Aspects of Spontaneous Abortion.
Dr. Elliott C. Cutler, Boston, Selection of Patients for Surgery.
Dr. Soma Weiss, Boston, Circulatory Collapse and Shock.
Dr. Perrin H. Long, Baltimore, Use of Sulfapyridine in Treatment of Pneumococcal Infections.
Dr. Edward Delos Churchill, Boston, Primary Carcinoma of the Lung.
Drs. Herman C. Pitts and George W. Waterman, Providence, Treatment of Carcinoma of the Cervix: Report on 135 Additional Cases with Five Year Results.
Drs. Albert H. Miller, Meyer Saklad and John A. Hayward, Providence, Symposium on Anesthesia.

The annual dinner will be held at the Pomham Club Thursday evening with Dr. Reginald Fitz, Wade professor of medicine, Boston University School of Medicine, as the guest speaker.

VIRGINIA

Personal.—Dr. Thomas E. Painter, assistant physician at the Eastern State Hospital, Williamsburg, has been appointed clinical director of the hospital.——A soft ball diamond in the state fair grounds was recently named in honor of Dr. William H. Parker, Richmond. The field was officially dedicated at the opening league game in April at which time Dr. Parker was guest of honor.

New Committee on Industrial Health.—The Medical Society of Virginia has appointed a committee on industrial health with the following members: Drs. Fred J. Wampler, Richmond, chairman; William D. Tillson, Richmond, and Horace T. Hawkins, Waynesboro.

WEST VIRGINIA

New Marriage Law in Effect.—A law requiring a physical examination and a blood test for syphilis of all applicants for marriage licenses went into effect in West Virginia May 26. The serologic test and the laboratory in which it is performed must be approved by the state department of health and the test must be made within thirty days before the marriage. The laboratory is to make two reports to the physicians: one stating the exact result of the test, the other stating the name of the test, the date and the name and address of the persons tested but not the result. Plans are now being worked out whereby laboratories will be approved for this work.

WISCONSIN

Society News.—Dr. Forrester Raine, Milwaukee, addressed the La Crosse County Medical Society, La Crosse, May 9 on "Water Metabolism."——Dr. Mynie G. Peterman, Milwaukee, recently addressed the Fond du Lac County Medical Society on "Convulsions in Childhood."——Dr. Siegfried F. Strauss, Chicago, addressed the Rock County Medical Society, Beloit, April 25 on "Subtotal Gastrectomy for Gastric and Duodenal Ulcer and Surgery of the Colon."——At a meeting of the Racine County Medical Society, Racine, April 20 the speakers were Drs. Philip Thorek, Chicago, and Jerrold Peerman Nesselrod, Evanston, Ill., on "Intestinal Obstruction" and "Anorectal Conditions" respectively.——Drs. Leo A. Hilger and Alexander R. Colvin, St. Paul, addressed the Pierre-St. Croix Counties Medical Society, Baldwin, recently on fractures of the hip.——Drs. John E. Gonce Jr. and John W. Harris, Madison, addressed the Oneida-Vilas County Medical Society, Rhinelander, May 11 on "Diseases of Early Infancy" and "Occiput Posterior Arrests" respectively.——The Milwaukee Neuro-Psychiatric Society went to Madison for its meeting May 4. The speakers were Drs. William F. Lorenz, on "A Rapid Flocculation Test for Syphilis Adapted to Cerebrospinal Fluid"; Helen E. P. Davis, "Anorexia Nervosa," and Mabel G. Masten, "Neurologic Complications of Chickenpox." Dr. Joseph Pessin reported a case of catatonic-like behavior in a 4 year old girl, with moving pictures, and Dr. Frank O. Meister demonstrated neuropathologic slides in color.

GENERAL

American Orthopaedic Association.—The annual meeting of the American Orthopaedic Association will be held in Buffalo, N. Y., June 5-8 at the Hotel Statler. Two sessions will be devoted to symposiums on acute hematogenous osteomyelitis and on fractures of the shaft of the femur. In addition, the program will include addresses by the following:

Drs. John G. Kuhns and Louis Nathan, Boston, Epiphysitis of the Spine.
Dr. Harold H. Hitchcock, Oakland, Calif., Spondylolisthesis.
Dr. William E. Gallie, Toronto, Canada, Ununited Fracture of the Neck of the Femur Treated by Combining the Smith-Petersen Nail and Bone Graft Without Opening the Hip Joint.
Dr. Marius N. Smith-Petersen, Boston, A New Approach to the Wrist Joint.
Dr. Cly Howard Hatcher, Chicago, End-Results of Epiphysial Arrests Operations.
Drs. Kellogg Speed and Egbert H. Fell, Chicago, Temperature Controlled Healing of Experimental Fractures.
Dr. Louis C. Kress, Buffalo, Malignant Disease.

American Ophthalmological Society.—The seventy-fifth annual meeting of the American Ophthalmological Society will be held at The Homestead, Hot Springs, Va., June 5-7 under the presidency of Dr. Frederick T. Tooke, Montreal. The program will include the following addresses:

Dr. Arthur M. Yudkin and Harriet A. Geer, Ph.D., New Haven, Conn., An Investigation of Experimental Cataracts in the Albino Rat—Clinical Implications.
Dr. Mark J. Schoenberg, New York, Psychosomatic Relationships—Therapeutic Implications for Patients with Glaucoma.
Mr. H. M. Traquair, Edinburgh, Scotland, Some Problems in Perimetry.
Dr. Alexander E. MacDonald, Toronto, Can., Six Cases of Lindau's Disease—Four Verified and Living.
Dr. Frederick A. Davis, Madison, Wis., Plexiform Neurofibromatosis (von Recklinghausen's Disease) of the Orbit and Globe.
Dr. Edward Jackson, Denver, Medical Ophthalmology.
Dr. Arnold Knapp, New York, The Course of Certain Cases of Optic Atrophy with Cupping and Low Tension.
Drs. Jonas S. Friedenwald and Wilhelm Buschke, and Harry O. Michel, Ph.D., Baltimore, The Role of Ascorbic Acid in the Mechanism of Secretion of the Intraocular Fluid.
Dr. Frederick H. Verhoeff, Boston, Hyperphoria Tests Based on a New Principle.
Drs. Phillip Robb McDonald and Francis H. Adler, Philadelphia, The Effect of Anoxemia on Dark Adaptation in the Normal and Vitamin A Deficient Person.
Drs. Henry P. Wagener and Paul L. Cusick, Rochester, Minn., The Retina in Surgically Treated Cases of Primary Hypertension.
Dr. Phillips Thygeson, New York, Treatment of Trachoma with Sulfanilamide.

Tuesday evening June 6 a banquet celebrating the seventy-fifth anniversary will be held with Dr. Harry Friedenwald, Baltimore, Mr. Traquair and Dr. Bernard Samuels, New York, as speakers.

Industrial Physicians' and Surgeons' Meeting.—The American Association of Industrial Physicians and Surgeons and the American Conference on Occupational Diseases and Industrial Hygiene will hold their annual meeting in Cleveland June 5-8 at the Hotel Statler under the presidency of Dr. Clarence D. Selby, Detroit. Among addresses to be delivered are:

Dr. Royd R. Sayers, U. S. Public Health Service, Washington, D. C., Health of Workers.
David B. Dill, Ph.D., Arlington, Mass., Fatigue in Industry.
Dr. Sumner L. S. Koch, Chicago, Tendon and Nerve Suture.
Dr. Donald M. Glover, Cleveland, Plastic Surgery in Relation to Industrial Injuries.
Dr. Henry H. Kessler, Newark, N. J., Operative Problems in Rehabilitation of the Injured.
Dr. John S. Coulter, Chicago, Physiotherapy Problems in Rehabilitation of the Injured.

The Knudsen Award to the physician judged to have made the outstanding contribution to industrial medicine during the year will be presented by the donor, Mr. W. S. Knudsen, president of the General Motors Corporation, at the annual banquet Wednesday evening June 7.

American Neurologic Meeting.—The sixty-fifth annual meeting of the American Neurological Association will be held in Atlantic City June 5-7 under the presidency of Dr. Williams B. Cadwalader, Philadelphia. There will be a symposium on virus disease and the central nervous system presented by Drs. Albert B. Sabin, New York, who will discuss "The Mode of Entry and Spread of Viruses in the Central Nervous System"; Howard A. Howe, Baltimore, "The Problem of Virus Infection in Poliomyelitis"; Leroy D. Fothergill, Boston, "Equine Encephalomyelitis in Man"; Joseph E. Smadel, New York, "The Use of the Complement-Fixation Test in the Diagnosis of Lymphocytic Choriomeningitis." Other speakers include:

Drs. Ernest Sachs and Henry G. Schwartz and Alan S. Kerr, St. Louis, Electrical Activity of the Exposed Human Brain.
Drs. William G. Lennox, Frederick A. Gibbs and E. L. Gibbs, Boston, The Inheritance of Epilepsy as Revealed by the Electroencephalograph.
Drs. Loyal Davis and John Martin, Chicago, The Result of Experimental Removal of the Pineal Gland.
Curt P. Richter, Ph.D., Baltimore, Transmission of Taste Sensation in Animals.
Drs. Francis C. Grant, Lawrence M. Weinberger and John H. Gibbon, Philadelphia, Anoxemia of the Central Nervous System Produced by Temporary Complete Arrest of the Circulation.
Drs. Lewis D. Stevenson, Anna M. Allen and Lillian E. McGowan, New York, A Study of the Brain Changes in Alcoholism.
Drs. James S. Robertson, Glasgow, Scotland, and Arthur E. Childe, Montreal, Can., Ventricular Asymmetry in Relation to Contracting Intracranial Lesions.
Drs. Wilder G. Penfield and Storer P. Humphreys, Montreal, Epileptogenic Lesions of the Brain: A Histologic Study.
Dr. Samuel D. Ingham, Los Angeles, The Neural Basis of Knowledge and the Synthesis of Concepts.
Drs. John McDowell McKinney and Maurice Frocht, New York, Seven Cases of Adie's Syndrome with Moving Picture Demonstration.

National Tuberculosis Association.—The thirty-fifth annual meeting of the National Tuberculosis Association will be held in Boston June 26-29, with headquarters at the Hotel Statler. The opening general meeting will be held Monday evening June 26, when Dr. Henry Chesley Bush, Livermore, Calif., will deliver his presidential address and the Trudeau Medal will be awarded. At a joint session of the pathologic and clinical sections there will be symposiums on (1) genitourinary tuberculosis, presented by Drs. Oscar Auerbach, Staten Island, N. Y., and Gilbert J. Thomas, Minneapolis; (2) spinal tuberculosis, Drs. Theodore A. Willis, Cleveland, and Mather Cleveland, New York, and (3) atelectasis, Drs. Max Pinner, New York, and Edward N. Packard, Saranac Lake, N. Y. There will also be a joint symposium on "Mass Tuberculin Testing and X-Raying" before the pathologic, clinical, social work and administrative sections by Drs. Esmond R. Long, Philadelphia; Bruce H. Douglas, Detroit, and James A. Doull, Cleveland. Among other speakers will be:

Dr. Harry J. Corper and Maurice L. Cohn, Ph.D., Denver, Phases of Intoxication in Tuberculosis.
Drs. Andre Cournand and Dickinson W. Richards Jr., New York, Pulmonary Function in Pulmonary Tuberculosis Under Various Forms of Collapse Therapy.
Dr. Moses J. Stone, Boston, Clinical Studies of Asbestosis.
Clair E. Turner, Dr.P.H., Cambridge, Mass., Training of Health Educators.
Dr. Herman E. Hilleboe, St. Paul, How Many Tuberculosis Patients Survive?

Medical clinics have been arranged for Wednesday afternoon June 28 at Boston City Hospital, Massachusetts General Hospital, Middlesex County Sanatorium, New England Deaconess and Peter Bent Brigham hospitals. Clinics on topics for lay workers have also been arranged.

Foreign Letters

LONDON

(From Our Regular Correspondent)

May 6, 1939.

Gas Masks in the Operating Room

The menace of poison gas has led to extraordinary precautions, such as the providing of gas masks specially made for babies. The latest contingency to be considered is the presence of the surgeon in the operating room. In a communication to the *British Medical Journal* (April 29, page 897) the surgeon Mr. J. S. Rowlands asks "Have surgeons considered the possibility of wearing gas masks during operation?" He endeavored to do this and planned a rehearsal at his hospital with the entire operating room staff wearing gas masks but gave up the idea and wore the mask alone during an operation for disarticulation at the cubometatarsal joint. When he donned the mask he was confronted with a series of problems. The coarser part of the operation, the disarticulation, was accomplished, but when it came to the finer points he was compelled to discard the mask. He found the mask entirely unsuited for this work. He therefore suggests that the Royal College of Surgeons and the Association of Anaesthetists should appoint a committee to discuss the problem and give guidance for a highly probable contingency. Hospitals with operating rooms on the ground level will be particularly concerned. In an editorial note the *British Medical Journal* states that, if it were possible for the surgeon and his assistants to operate in gas masks on a patient wearing a gas mask, the choice of an anesthetic would be limited.

The subject has already been discussed on the European continent. Von Fehr (*Schweiz. med. Wchnschr.* **69**:347 [April 15] 1939) suggests that the surgeon should learn to work in a gas mask, just as the soldier has to do. The *Lancet* states that the army surgeon Colonel Cowell successfully completed an appendectomy wearing a gas mask. The haversack hung over his back instead of in front and the sterilized overall was tied loosely so as to allow the entry of air. There was no difficulty as to comfort, visibility or efficiency.

Scientists in Wartime

H. G. J. Moseley worked for four years with Rutherford and at the age of 26 completed a research which the American physicist R. A. Millikan described as "destined to rank as one of the most brilliant in the history of science. He threw open the windows through which we can glimpse the subatomic world with a definiteness and a certainty never dreamt of before." He was killed in the war at the Dardanelles at the age of 27. Physicists regard this as a disaster which deprived the world of the natural successor to Rutherford. The loss to his country far outweighed any services he could have performed in the war. It is felt that if another war occurs such loss of scientific ability should as far as possible be avoided. The Royal Society has therefore prepared for the government a register of scientists engaged in or qualified for research. The work has been done by a committee under the chairmanship of the physiologist A. V. Hill. There are ten subcommittees, of which some of the chairmen are Dr. C. G. Darwin (mathematics), Dr. E. V. Appleton (physics) and Prof. D. M. S. Watson (zoology). Scientists invited to join the register receive a classification table of seventy-seven sciences and two registration cards. The scientist gives the science in which he is best qualified first place on the card and then names the other subjects in the order of his competence. A curious fact is that young scientists put down a considerable range of subjects. One man aged 22 entered as many as eighteen. But older men give only a few. Registration carried the obligation of the scientist to place his services at the disposal of the government in the event of war. It is thus hoped that the scientific ability of the country will be better employed than in the earlier years of the late war.

The Evacuation of Cities in Case of War

The following are further particulars of the arrangements made by the government for the removal of the inhabitants of cities from the peril of air attack. A billeting survey has shown that accommodation can be found for 5,000,000 persons in the country. The government is arranging for the movement of 3,000,000 without interfering with another 1,000,000 who have reserved accommodations for themselves under private arrangements. The 3,000,000 include 2,500,000 children, who would be moved at the rate of 1,000,000 a day. When the official movement begins, absolute priority in all rail and road traffic will be given to the children and those in charge of them. Persons who propose to move privately are therefore advised to leave well in advance of an emergency, even at the risk of a wasted journey. The government will not be able to advise them. Precise timetables and destinations are now being worked out in detail. Special provision is to be made for expectant mothers. Any mother who already has one child under 5 years of age will automatically be moved with her children. A large number of nurses, now being recruited and registered by the Central Emergency Committee, will be available in the reception areas for welfare work and nursing the sick.

The Storage of Radium in Wartime

The secretary of the National Radium Commission points out in a letter to the press that if any quantity of radium was dispersed by violence during an air raid, the buildings in which it was dispersed, as well as the surrounding area, would for many years be a menace to the people who inhabited them. The inhalation of 0.01 mg. would probably be fatal. It is therefore necessary that steps be taken to provide for the safe custody of radium in wartime. For this purpose a conference has been held between representatives of the British X-Ray and Radium Protection Committee, King Edward's Hospital Fund for London, the Ministry of Health and the National Radium Commission. The last is compiling a list of owners and holders of radium with a view to satisfactory arrangements being made. All who have the custody of radium are requested to notify the commission and state the amount.

PARIS

(From Our Special Correspondent)

April 29, 1939.

Cardiosurgery

At a session of the Société de médecine of Paris devoted to omentopexy, Dr. O'Shaughnessy of London explained his grafting technic of revascularization of the heart; an interesting colored film accompanied his communication. One of the problems of omentopexy is the reality of the new anastomoses which are supposed to be established between the myocardium, ischemic as a result of coronary insufficiency, and the epiploic or muscular graft. Of the four solutions having as a basis the cardiac graft, i. e., graft of the pectoral muscle, graft of the lung, graft of the omentum and production of pericardiac adhesions vascularized by irritation of the pericardium, O'Shaughnessy has chosen omentopexy, or grafting of the omentum. He used this method, the technic of which is in reality rather simple though demanding great surgical dexterity, with twenty patients, whose condition was sufficiently grave to justify an operation so new and so audacious, and he gives as proof of his prudence in this respect the fact that several of his patients were in such a grave condition that they died before they could be operated on.

Fifteen of the twenty patients had angina pectoris and five had symptoms of cardiac ischemia. In the first group, five of those who were operated on died, one in the course of the operation, another of uremia three months later and three of heart failure two years later. All the survivors recovered completely. In the second group none died. The operative risks do not seem to be greater than the risks inherent in the future of seriously affected patients. O'Shaughnessy presented anatomic specimens and microscopic plates which demonstrated the reality of the formation of new vessels between the graft and the myocardium.

The indications for this operation are not yet fixed with precision. Cardiac failure due to hypertension and aneurysms of the heart are among the most clearcut.

According to Heim de Balsac, who succeeded the English surgeon on the rostrum, the indications for omentopexy are derived rather from the ischemia caused by coronaritis than from the anginal pain, which is not always of ischemic origin whereas the numerous types of coronaritis are not all painful.

It may be recalled that for two years O'Shaughnessy tried the same ideas in the surgical treatment of renal sclerosis, by fixing to the decapsulated kidney an epiploic graft. Abrami and Iselin have just reported in the *Presse médicale* two new attempts of this kind, which have given satisfactory results.

Anatoxin

Nélis, presenting before the Académie de médecine recent statistics on vaccination with anatoxin in Belgium, declared that vaccination with anatoxin was rather timidly attempted in 1924 and met with growing success. On the basis of the quantity of vaccine used in 1929, allowing 15 per cent for loss, it has been calculated that at least 330,000 children have been vaccinated with anatoxin. This means 33,000 children a year, or 14 per cent of Belgian children between the ages of 1 and 15 years. However, this seems to represent a small proportion.

The anatoxin used in Belgium is supplied for the most part by the Pasteur Institute of Brussels; the rest is supplied, with few exceptions, by the Pasteur Institute of Paris. The two products are identical in composition and value. The anatoxin is subjected to triple official control as to sterility, innocuousness and antigenic unit contents in every case. The conclusions of Nélis are explicit; among 330,000 vaccinated children not one serious complication was observed in spite of the different controls by the bureaus of hygiene.

Prophylaxis of Malaria

In the northern part of French Indo-China there are enormous plantations of hevea where malaria is endemic. The marshy character of the land favors the breeding of Anopheles, and the way of living of the coolies makes them particularly vulnerable.

The fight against malaria was first carried on with quinine, to which were added, on the instigation of the Pasteur Institute, synthetic medicines, such as atabrine and "praequine." In certain regions, prophylaxis was brought about with these drugs alone.

The semimilitary regimen to which workers on hevea plantations are subjected in these regions permitted accurate control of the treatment and of the malarial indexes, and these precise conditions for experiments prompted Canet to report before the Société de pathologie exotique his ideas for the complete and final eradication of malaria. He concluded that it was not possible to attain such eradication solely by medication, even with synthetic antimalaria medicines, on account of the frequency of reinfections, the persistence of the reservoirs of the virus and the quickly reached limit of the effect of the drug.

Synthetic medicines are excellent temporary remedies, especially in an epidemic; however, definite measures have to be added, like drainage of stagnant waters, amelioration of social conditions and strict control of the infected.

The atabrine of the Pasteur Institute, at the optimal dose of 0.3 Gm., is capable, nevertheless, of subduing rapidly the periodic or exceptional attack. Moreover, it is taken more readily by the natives than quinine. Its administration is subjected to epidemiologic and geographic considerations particular to each case.

Deaths

Prof. Prosper Merklen, a teacher of clinical medicine at the Faculty of Medicine of Strasbourg, is dead. He was a pupil of Widal, and he wrote important articles, especially on heart disease. His ancestors came from Alsace, and when Alsace was returned to France after the World War he finished his medical studies at the Faculty of Medicine of Strasbourg. He was a dean of the faculty until 1933, when he retired.

Victor Pachon died recently at the age of 70. With his youthful days ardently devoted to work, often under distressing material conditions, he merited the professorship of physiology at the Medical Faculty of the University of Bordeaux by his genius for experimentation. He laid down the notion of oscillometry, and the term a pachon is used in France to designate the oscillometer, which became indispensable in medical practice.

BERLIN

April 10, 1939.

Stimulants Endanger Public Health

At the beginning of March a governmental convention on public health and the use of stimulants was held in Frankfort on the Main, convoked by the central department on public health in conjunction with the bureau of the reich against the misuse of alcohol and tobacco. The purpose of the meeting, attended by about 15,000 persons, was to discuss the increasing consumption of alcohol and tobacco with the consequent increased outlay (more than 7 billion marks in 1938). It was stressed that to allow this situation to continue was to endanger public health. Neither abstinence nor prohibition was envisaged. According to the principles of the national socialist party the adult may choose between abstinence and temperance; youths, however, are expected to abstain. The aim must be to curtail the increase in the use of these stimulants within a reasonable time.

The Berlin surgeon Professor Sauerbruch, substitute speaker for the leader of physicians of the reich (reichsärzteführer), made no new contributions to the subject. He said that the speculative philosophy of idealism had for a long time led to an underestimation of all biologic processes and that the national socialist party must be credited with bringing about the conception of the organic relation between the physical and the mental. It was his concern, he said, as a university teacher and educator of future physicians, to develop a medical group that warm-heartedly and with open eyes would welcome the new order. Dr. Ley, director of organization for the reich, who had had full charge both of the planning and of the conduct of this meeting, expressed himself in favor of complete abstinence. He was convinced from personal experience that temperance in the long run would fail. Five years ago, he said, he had to face the choice of giving the best service or allowing stimulants gradually to impair his efficiency. He associated the potential efficiency of old age with the use of alcohol and tobacco, having in mind habitual small uses, not excessive indulgence. The objective must be not to retire on a pension after a certain age but to be able to work when 80 years old. He branded the assertion that the ancient Germans had been topers a fiction created by their archenemies the Romans. Moderns would call the mead they drank fruit juice.

The president of the governmental department of public health announced that all medical societies of the nation had been requested, in conjunction with the proper institutions, to determine scientifically whether and to what extent the use of tobacco stood in any causal relation to diseases. A representative from the governmental office of race and politics referred to well known drinking bouts (kommers) characteristic of German student clubs as "collective compulsion" of oriental origin. Simultaneously with this meeting a conference of educators was held in which emphasis was laid on the fact that abstention from stimulants was a matter not of prohibition but of education. The misuse of tobacco and alcohol was brought into close connection with the "liberalism" of the times preceding the Nazi régime.

In connection with this conference perhaps some data recently published by the governmental department of statistics may be of interest. The records indicating the use of numerous stimulants in Germany extend over a period of sixty years and show a surprising constancy. For example, the use of coffee since 1878, with some fluctuations, has remained nearly at the same level (1878, 2.25 Kg. annually per capita; 1936, 2.31 Kg.). The consumption of tea for the same period, with a slow upward trend, doubled (0.03 Kg. to 0.07 Kg.) but does not have an important role in Germany as compared with its fifty times greater consumption in England. The use of alcoholic beverages has fallen off considerably, although it has risen since 1933. The statistics are shown in table 1.

TABLE 1.—*Annual per Capita Consumption of Alcoholic Beverages and Tobacco*

Year	Beer, Liter	Alcohol, Liter	Tobacco, Kg.
1878.....	82.4	....	2.73
1900.....	117.9	5.33 (in 1907)	1.56
1913.....	102.1	2.56	1.56
1925.....	75.4	1.04	1.69
1929.....	90.0	0.75	1.98
1933.....	52.0	0.86	1.80
1936.....	58.8	1.00	1.78

This upward trend reflects partly the changes in the age level of the population, the number of adults having increased with increasing longevity. However, the highest postwar statistics in the case of coffee, wine and alcohol have been surpassed and in the case of tobacco almost reached. Likewise the increased consumption of beer is unmistakable. Full statistics are shown in table 2.

TABLE 2.—*Annual Consumption per Adult (Kg. or Liter)*

	1913	1929	1933	1936	1937
Tobacco	4.8	5.4	4.7	4.8	4.9
Beer	154.0	116.0	69.0	77.0	83.0
Alcohol	4.2	1.8	1.0	1.3	1.4
Wine	5.1	6.1	4.7	8.8	8.9
Coffee	2.4	2.2	1.8	2.1	2.4
Tea	0.1	0.1	0.1	0.1	0.1

Race and Heredity

Regarding race selection according to purpose, Dr. Gross, director of the department of race and politics, recently expressed himself in the *IVill of the People,* organ of the National Society of Large Families. The criteria of national race culture and selection differ according to the purpose for which selection in each case is made. As a criterion for proving one's worth in life one must require that the mental power of the men be sufficient for the discharge of military duty, especially for the severe demands of the highly developed modern military system, and that of the women for rearing useful children. For general purposes, the writer says, absence of serious defects is sufficient for most leading professions and positions. Greater racial and hereditary qualifications, however, will be demanded of military officers, party leaders and farmers. Racial selection consciously pursued rejects many persons, but all kinds of other possibilities are open to them in the life of the nation. In every case race and heredity must be considered from the point of view of the purpose for which the examination and selection are made.

According to a new law, persons who appear in court in disputes over family rights will be subjected to hereditary and racial investigations, so far as this is necessary to determine the descent of the child. These can be ordered also in other cases, for example in criminal actions for violation of the "law for the protection of German blood and honor" (that is, of social intercourse between Aryans and Jews). Such investigations, as the minister of justice pointed out, do not yield reliable results until the child is about 2 years old. In certain circumstances the governmental bureau of genealogy should be brought into the picture to make a thorough study, especially when descent from German blood is justifiably questioned.

On heredity and education an influential member of the bureau of race and politics who likewise represents the government department of education in matters of this kind expressed himself to the effect that one must not conclude, in view of our present knowledge on racial matters, that education is now replaced by hereditary destiny and no longer necessary. To be sure, he said, it is impossible to modify inherited traits by environment and to exercise an educational influence on race, yet the important thing is to develop the abilities latent in the individual and in the race. This can be done by environment. Environment can discover and promote or dwarf and stunt. The motto must therefore be "Heredity and environment."

AUSTRALIA

(From Our Regular Correspondent)

April 26, 1939.

National Health Insurance Fades Out

The political crisis occasioned by the sudden death of the prime minister, Mr. J. A. Lyons, has definitely sealed the doom of national health insurance in Australia. For some time it has been evident that the government wished to abandon the act placed on the statute book last year. But, national insurance being one of the main points of governmental policy on which the last election was won, such action would have required considerable courage, in spite of the almost national feeling against the act, which the government, in an already precarious position, has felt unprepared to meet. The issue was heatedly debated in the cabinet a few weeks ago. It was finally decided that, rather than abandon the whole of the National Health and Pensions Insurance Act, it should be replaced by a less comprehensive health scheme. This proposed scheme covers a smaller number of persons, they are asked to pay a smaller contribution, and the benefits to be gained are fewer. On the other hand, the scheme is to include dependents, so that, while the original 1,850,000 insured are reduced to 1,500,000, the addition of dependents raises the number eligible for medical attention to 3,000,000. Whether the lower revenue from insured contributors, the increase in the number of persons who are to receive treatment and the necessary increase in the payment of physicians to compensate for the almost total destruction of private practice are mutually compatible is apparently a moot point.

This alternate proposal was introduced only at the expense of the resignation of the attorney general, Mr. A. R. Menzies. Now Mr. Menzies has been recalled to assume prime ministership, and a new cabinet has been formed under his leadership. It is doubtful, however, whether this shift of power will be responsible for any significant change in the attitude toward

insurance. The rising noise of the drums of war becomes so insistent that national insurance will probably fade into oblivion behind the strident overtones of the question of defense. However, until parliament meets it is not possible to foretell what will be the fate of the present act. A mutilated section of the original may survive or it may be killed entirely, but even total repeal will not dispose of the matter finally. In effect it is only indefinite postponement. Sooner or later some form of national health insurance is inevitable.

Poliomyelitis

In 1937, during an epidemic of poliomyelitis in South Australia, it was observed that, of a number of children affected in a city where immunization against diphtheria had been carried out quite recently, the majority had not been immunized. Immunization had been carried out without previous Schick testing. Further investigation by W. G. Heaslip of Adelaide supported this observation. Patients with poliomyelitis and controls were subjected to the Schick test, and the 1917 finding of Zingher that a disproportionately large percentage of patients with poliomyelitis give a positive reaction to the Schick test was confirmed. From this and other observations it appears that a positive correlation exists between susceptibility to diphtheria and to poliomyelitis. Heaslip suggests that this relationship probably (*a*) is not confined to these two diseases and (*b*) has a constitutional defect underlying it.

VITAMIN C NUTRITION AND PROPHYLAXIS

Heaslip has also considered the relation of vitamin C nutrition to susceptibility to diphtheria and to poliomyelitis. The urinary excretion of vitamin C in various groups of infected and noninfected persons was estimated and a relation demonstrated between the infectious state and the value obtained. It has been shown that, while usually there is a decrease in the excretion of vitamin C following infection, it is probable that a low level of vitamin C and poor vitamin nutrition generally predispose to infection and severity of attack.

Kenny Treatment of Orthopedic Conditions

In a previous letter (THE JOURNAL, March 19, 1938, page 910), comment was made on a "new" system of treating long-standing infantile paralysis and other orthopedic conditions, devised by Sister Elizabeth Kenny and first practiced in Queensland. By her optimistic claims of cure, Miss Kenny soon roused public opinion and medical interest. At that time the report had just been issued of a royal commission appointed in Queensland to investigate her method as outlined in her textbook "Infantile Paralysis and Cerebral Diplegia." A terse medical criticism of her book was that "there was much in it both good and new. Unfortunately that which was good was not new, and that which was new was not good."

The report has now come to hand of a committee appointed by the London County Council to investigate her method of treatment as demonstrated at her clinic attached to Queen Mary's Hospital, Carshalton. The findings of this committee are similar to those of the Queensland commission, and the main conclusions are as follows:

1. There is no reason to admit that Miss Kenny's claim of complete cure can be promised in any group of cases of poliomyelitis.

2. The use of hydrotherapy in the form of hot and cold douches as practiced by Miss Kenny is of value.

3. Very early attempts to initiate voluntary movements and also early and frequent passive movements are harmless but of unproved value.

4. The committee agrees with Miss Kenny that under certain specified conditions splints can be dispensed with in the treatment of the disease in its early stages. It does not approve, however, of her entire abolition of splints and surgical appliances in treatment, as these are considered to be often valuable and sometimes essential parts of the treatment. On the other hand, the mechanical methods employed by Miss Kenny in substitution for splints are considered inadequate.

5. Miss Kenny has not really faced the issue of residual paralysis, for which surgical appliances or surgical methods, such as stabilizing operations, offer the only eventual hope of amelioration.

6. Some improvement appears to have been achieved in cases of cerebral spastic paralysis, but Miss Kenny's system in these cases demonstrated no original principles.

BUENOS AIRES

(From Our Regular Correspondent)

April 30, 1939.

Earthquake in Chile

In the violent earthquake which shook many Chilean areas into ruins, the most damaged towns were Chillán, Cauquenes and Concepción. Argentina sent immediately, by airplane, antitetanus and antigangrene serum. Material for installing an orthopedic hospital with 300 beds was sent by train. The hospital was installed in Santiago in charge of Drs. Denis, Ottolenghi, Allende and twelve assistant Argentine surgeons. During the first forty-eight hours more than 200 fractures, of which most were fractures of the spine and some were fractures of the cranium, were given attention in the hospital. Equipment for the disinfection of drinking water and for transfusion, as well as 50,000 liters of naphtha for aviation purposes, was also sent. The Chilean authorities worked constantly for good sanitary conditions in order to prevent epidemics. All donations made by Argentina were turned over to the Chilean medical body, which is large and very competent. Donations of economical resources, clothes and mattresses seemed to be more necessary for the time being than medical aid. Argentina sent donations of about 2,000,000 Argentine pesos ($500,000). Because of the five modern systems of transportation, much help from many lands was available and speedily given.

New Building of the Faculty of Medicine

The president of Argentina, in a decree of Nov. 16, 1938, allowed 16,847,680 Argentine pesos (about $5,000,000) for construction of the building of the Faculty of Medicine and its branches in Buenos Aires. This building will have an annex for the Faculties of Pharmacy and Odontology. The committee in charge of the work, presided over by Dr. José Arce, has been asked to prepare plans for the maternity building and the institute of pathologic anatomy and the polyclinics, the cost not to exceed 2,000,000 and 6,024,000 Argentine pesos ($500,000 and $1,500,000) respectively, equipment included. The construction of the building will begin immediately and is under contract with a German firm.

Marriages

WILLIAM DERREL HAZLEHURST, Charleston, S. C., to Miss Harriet Letcher McKay of Macon, Ga., in March.

WILLIAM BLAIR HARRISON, Athens, Tenn., to Miss Martha Nell Walton of Atlanta, Ga., March 6.

JAMES BOWRON MCLESTER, Birmingham, Ala., to Miss Meade Belden, New York, in March.

ROBERT ALEXANDER WHITE to Miss Mildred Baird, both of Asheville, N. C., March 16.

MAX EHRLICH to Miss Jeannette Gordon, both of Elizabeth, N. J., Dec. 26, 1938.

WALTER HENRY GERWIG JR. to Miss Olive Bowman, both of Baltimore, March 18.

Deaths

Charles Horace Mayo ⊕ noted as a surgical genius, a great medical administrator and a genial physician, died in Chicago of pneumonia, May 26. The younger of the two world-famed Mayo brothers was born in Rochester, Minn., July 19, 1865, the son of William Worrall Mayo and Louise Wright Mayo. After an education in the Rochester high school and at the Niles Academy he attended Chicago Medical College, later known as Northwestern University, and received his degree in medicine in 1888. As a young boy he began, almost from childhood, to live in a medical atmosphere and to become inspired toward medicine as a career. After his graduation in medicine he returned to Rochester, where his urge toward research and his surgical genius led to innumerable investigations in medicine and in surgery. His first published statement was a joint contribution with his brother, Dr. William J. Mayo, entitled "Report of Clinic in St. Mary's Hospital, Rochester, Minnesota, January 19, 1891," which was published in the *Northwest Lancet* in November of that year. From that time on hardly a year passed without a contribution by either Dr. Charles H. Mayo alone or with his brother, or with some of the younger men who soon became attracted to them. These contributions cover every phase of medicine and surgery and in later years embrace as well the fields of philosophy, economics and statesmanship.

CHARLES HORACE MAYO, M.D., 1865-1939

In the field of scientific medical organizations Dr. Charles H. Mayo was president of the Western Surgical Association in 1904, the Minnesota State Medical Association in 1905, the Society of Clinical Surgery in 1911, the Clinical Congress of Surgeons of North America in 1914, the American Medical Association in 1916, the American College of Surgeons in 1924, the American Surgical Association in 1931 and the Minnesota Public Health Association from 1932 to 1936.

Many of the greatest universities in the world conferred honorary degrees on him. Thus the master of arts degree was conferred by Northwestern University in 1904, fellowship in the Royal College of Surgeons in England in 1920 and in the Royal Society of Medicine in 1926, and master in chirurgery by Trinity College of Dublin in 1925. He was made doctor of public health by the Detroit College of Medicine and Surgery in 1927 and doctor of science by Princeton University in 1917, the University of Pennsylvania in 1925 and the University of Leeds in England in 1909. He also received the honorary degree of LL.D. from the University of Maryland in 1909, Kenyon College in 1916, Northwestern University in 1921, the University of Edinburg in Scotland in 1925, Queen's University in Belfast, Ireland, in 1925, University of Manchester in England in 1929, Hamline University in 1930, and Carleton College in 1932.

A number of great nations also honored him with citations for distinguished service, the record including officier de l'Ordre national de la legion d'honneur, France, 1925; officier de l'Instruction publique et des beaux-arts, France, 1925, and Cross of Knight Commander of the Royal Order of the Crown of Italy, 1932, as well as citations from many other countries.

During the World War he and his brother, Dr. William J. Mayo, alternated between Rochester, where they maintained graduate study for physicians entering the service, and the personnel department in Washington. They served also as consultants in surgery. Dr. Charles H. Mayo was commissioned Major on April 19, 1917, Colonel June 15, 1918, and Brigadier General Nov. 22, 1921. He received the distinguished service medal of the United States Army on June 7, 1920. With Dr. William J. Mayo he was cited for distinguished service by the National Organization of the American Legion and presented with a commemorative plaque, the special ceremony being conducted by President Franklin D. Roosevelt in person in 1934.

The list of his membership in distinguished civic and medical organizations, both American and foreign, is far too long to list. To many of these he gave personally of himself and of his advice, in others he held honorary membership only. He gave also freely of himself and of his work to many scientific and general publications. He served as health officer of the city of Rochester since May 1, 1912, and as a member of the school board of that city from 1915 to 1923.

In 1915 Drs. William J. and Charles H. Mayo established the Mayo Foundation for Medical Education and Research in Rochester, affiliating this organization with the University of Minnesota. Their first contribution was $1,500,000, which has now been increased to more than $2,650,000. In order to perpetuate this institution, the Mayo Properties Association was established in 1919 to hold all the property, endowments and funds of the Mayo Clinic and to insure the permanence of the institution for public service with the understanding that the moneys and property can never inure to the benefit of any individual.

Dr. William J. Mayo, Dr. Charles Horace Mayo and their distinguished father made a small village become one of the most notable medical centers of the world. Throughout their careers these distinguished leaders devoted themselves to the advancement of organized medicine. The medical society of the county in which they practiced was founded by Dr. William Worrall Mayo. Dr. Charles H. Mayo was widely known not only as a surgical genius, as a great surgical teacher, as an inspired organizer, as a leader in medical advancement and as a citizen of his city, county, state and of the nation, but also as a warm hearted, genial, faithful, true humanitarian, easily approachable, unostentatious, ready to trade wits and banter, always in the most kindly and sympathetic manner. Such men come but infrequently in any civilization and their places are not easily filled as the world moves on.

Henry Khunrath Pancoast ⊕ Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1898; professor of radiology at his alma mater and the Medico-Chirurgical College, Graduate School of Medicine, University of Pennsylvania; chairman of the Section on Radiology of the American Medical Association, 1931-1932; member, past president and secretary of the American Roentgen Ray Society and the American Radium Society; member and past president of the American College of Radiology and the Philadelphia Roentgen Ray Society; past president of the first American Congress of Radiology; member of the Radiological Society of North America; first president in 1934 of the examining board of the American Board of Radiology; member of the board of directors and from 1932 to 1935 member of the executive committee of the American Society for the Control of Cancer; served in the navy during the World War; consulting physiologist to the United States Bureau of Mines, 1923-1938; served at various times and in various capacities on the staffs of the University of Pennsylvania Hospital, Bryn Mawr (Pa.) Hospital, Chestnut Hill Hospital and the Philadelphia General Hospital; author, with E. P. Pendergrass, of "Pneumoconiosis (Silicosis): A Roentgenological Study with Notes on Pathology," published in 1926; aged 64; died, May 20, at his home in Merion Station.

Antonie Phineas Voislawsky ⊕ New York; Dartmouth Medical School, Hanover, N. H., 1897; member of the American Laryngological Association, American Laryngological, Rhinological and Otological Society and the American Otological Society; fellow of the American College of Surgeons; laryn-

gologist and chief of clinic, St. Luke's Hospital; attending otolaryngologist, Staten Island Hospital, Tompkinsville; laryngologist to the Fifth Avenue Hospital; consulting otologist to the Harlem Eye, Ear and Throat Infirmary, Manhattan Maternity and Dispensary, New York, Northern Westchester Hospital, Mount Kisco; consulting laryngologist to the New York Society for Relief of the Ruptured and Crippled; aged 66; died, February 22, in the Neurological Institute of brain tumor.

Maurice Brodie, Detroit; McGill University Faculty of Medicine, Montreal, Que., 1928; National Research Fellow in Medicine, 1933-1934; at one time assistant professor of bacteriology at the New York University, University and Bellevue Hospital Medical College; member of the American Association of Pathologists and Bacteriologists and the Society of American Bacteriologists; formerly in charge of infantile paralysis research at the Bureau of Laboratories, New York City Health Department; assistant director of laboratories, Providence Hospital; was widely known for his research on the treatment and causes of infantile paralysis; author of numerous articles on the subject; aged 35; died, May 9.

James Clifton Edgar ✠ Greenwich, Conn.; University of the City of New York Medical Department, 1885; professor emeritus of obstetrics, Cornell University Medical College; at various times instructor of pathology, lecturer in obstetrics and adjunct professor at the New York University; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; consulting obstetrician to the Bellevue, New York Maternity and Jewish Maternity hospitals, New York, and Greenwich (Conn.) General Hospital; author of "The Practice of Obstetrics," published in 1903; aged 79; died, April 7, of chronic myocarditis, arteriosclerosis and chronic prostatitis.

Gatewood ✠ Chicago; Rush Medical College, Chicago, 1911; clinical professor of surgery at his alma mater; member of the American Surgical Association and the Western Surgical Association; fellow of the American College of Surgeons; associate attending surgeon to the Presbyterian Hospital for many years; attending surgeon to the Cook County Hospital and the Highland Park (Ill.) Hospital; treasurer of the Chicago Surgical Society; author of numerous articles in various surgical journals; aged 51; died suddenly May 22, at his home in Highland Park, Ill., of heart disease.

William Crooks Thro, Long Island City, N. Y.; Cornell University Medical College, New York, 1907; member of the American Association of Anatomists, American Association of Pathologists and Bacteriologists, Society of American Bacteriologists and the American Society of Clinical Pathologists; at one time assistant professor of clinical pathology at his alma mater, and associate professor of medicine (clinical pathology); formerly pathologist to St. Mark's Hospital and visiting pathologist to the Reconstruction Hospital; aged 63; died, April 6.

James Henry Kenyon ✠ New York; Columbia University College of Physicians and Surgeons, New York, 1898; at one time adjunct professor of surgery, Fordham University School of Medicine; member of the American Association for Thoracic Surgery; fellow of the American College of Surgeons; served during the World War; visiting surgeon to the Fordham Hospital; associate surgeon to the New York Neurological Institute; on the staff of the Booth Memorial Hospital; aged 66; died, April 10, of coronary thrombosis.

Robert Sattler ✠ Cincinnati; Miami Medical College, Cincinnati, 1875; professor emeritus of ophthalmology at the University of Cincinnati College of Medicine; member and past president of the American Ophthalmological Society; fellow of the American College of Surgeons; aged 83; ophthalmic surgeon to the Cincinnati General Hospital and medical director of the Ophthalmic Hospital, where died, February 20, of coronary thrombosis.

Harris Holmes Vail ✠ Cincinnati; Harvard University Medical School, Boston, 1917; member of the American Academy of Ophthalmology and Oto-Laryngology and the American Otological Society; instructor of otolaryngology, University of Cincinnati College of Medicine; served during the World War; on the staffs of the Cincinnati General Hospital, Christ Hospital and the Good Samaritan Hospital; aged 47; died, April 10, of angina pectoris.

Herbert Fleming Wilson, Covington, Ky.; Hospital College of Medicine, Louisville, 1901; member of the Kentucky State Medical Association; formerly city health officer and member of the board of health; at one time served in various capacities at the William Booth Memorial Hospital and St. Elizabeth Hospital; aged 63; died, February 1, of angina pectoris.

Andrew Phillips Albaugh, Tarpon Springs, Fla.; Miami Medical College, Cincinnati, 1887; member of the Florida Medical Association; past president of the Pinellas County Medical Society; for many years president of the city council and member of the local school board; city health officer; aged 76; died, March 16, of cerebral hemorrhage.

William Allen White, Boston; Tufts College Medical School, Boston, 1894; member of the Massachusetts Medical Society; assistant in theory and practice of medicine, 1893-1894, and lecturer, diseases of children, 1893-1897, at his alma mater; aged 74; on the staff of the Massachusetts Women's Hospital, where he died, February 6, of pneumonia.

Marshall Flowers Lummis ✠ Pitman, N. J.; University of Pennsylvania Department of Medicine, Philadelphia, 1901; past president of the Gloucester County Medical Society; served during the World War; medical inspector in the schools; aged 59; died, February 25, in the Hahnemann Hospital, Philadelphia, of staphylococcic septicemia.

William Albert Jones, Homestead, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1897; member of the Medical Society of the State of Pennsylvania; physician for the department of child welfare and city board of education; aged 65; died, February 21, in the Homestead Hospital of angina pectoris.

Robert D. Voorhies ✠ Lafayette, La.; Hahnemann Medical College and Hospital, Chicago, 1895; served during the World War; on the staff of the Lafayette Charity Hospital; aged 66; died, February 9, in the Hotel Dieu, Sisters' Hospital, New Orleans, of coronary thrombosis and chronic myocarditis.

Allen Francis Gillihan, San Luis Obispo, Calif.; University of California Medical Department, San Francisco, 1899; served as health officer of Oakland, district health officer for the state board of health and health officer of San Luis Obispo County; aged 66; died, February 15.

Clarence Willard Winbigler, Harper, Kan.; Bellevue Hospital Medical College, New York, 1877; member of the Kansas Medical Society; aged 85; died, February 26, in the Hatcher Hospital, Wellington, of chronic infection of the urinary tract with kidney failure.

Henry Edwin Waterhouse ✠ Bridgeport, Conn.; Columbia University College of Physicians and Surgeons, New York, 1902; fellow of the American College of Surgeons; chief obstetrician to the Bridgeport Hospital; aged 61; died, February 4, of coronary occlusion.

Lonnie Doak Allen, Smithville, Tenn.; University of Nashville Medical Department, 1898; at one time secretary of the De Kalb County Medical Society; formerly bank president; for many years county physician; aged 67; died, March 5, of pneumonia.

Robert Norton Downs Jr., Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1895; on the staff of the Germantown Dispensary and Hospital; aged 65; died, February 9, of chronic myocarditis and coronary sclerosis.

Troy Curtis Sexton ✠ Las Cruces, N. M.; Medical Department of Tulane University of Louisiana, New Orleans, 1902; for many years secretary of the Dona Ana County Medical Society; formerly mayor; aged 61; died, February 23, of angina pectoris.

David Ward Magee, Caseyville, Miss.; University of Nashville (Tenn.) Medical Department, 1907; member of the Mississippi State Medical Association; served during the World War; aged 55; died, February 12, of carcinoma of the colon and rectum.

Frederick Marshall Parker, Halifax, N. C.; University College of Medicine, Richmond, Va., 1897; for many years physician to the Caledonia Prison Farm; aged 63; died, February 13, in the Park View Hospital, Rocky Mount, of pneumonia.

Edward Augustine Supple, Boston; Harvard University Medical School, Boston, 1907; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; aged 56; died, February 26, in the Audubon Hospital of pneumonia.

George Washington Newman, Montrose, Pa.; Hahnemann Medical College and Hospital of Philadelphia, 1903; member of the Medical Society of the State of Pennsylvania; county jail physician; aged 65; died, February 7, of coronary thrombosis.

John Henry Rapp, Wichita, Kan.; University of Colorado School of Medicine, Denver, 1913; member of the Kansas Medical Society; served during the World War; aged 49; died, February 18, in St. Francis Hospital of lobar pneumonia.

John Stimson Woolery ✠ Bedford, Ind.; Indiana University School of Medicine, Indianapolis, 1933; county health officer; aged 33; died, February 3, in the Methodist Hospital, Indianapolis, of injuries received in an automobile accident.

John Kirkland Ross, Charlotte, N. C.; Jefferson Medical College of Philadelphia, 1907; served during the World War; formerly connected with the U. S. Veterans Bureau; aged 61; died, February 19, of heart disease and diabetes mellitus.

Charles Mortimer Smith ⊕ Evansville, Wis.; Rush Medical College, Chicago, 1890; for many years city health officer and member and chairman of the county board of supervisors; aged 72; died, February 23, of cerebral hemorrhage.

Ira Miltimore ⊕ Gary, Ind.; Rush Medical College, Chicago, 1903; fellow of the American College of Surgeons; on the staffs of the Mercy and Methodist Episcopal hospitals; aged 58; died, February 14, of coronary occlusion.

Henry Clinton Bembry, Philadelphia; Howard University College of Medicine, Washington, D. C., 1910; aged 59; died, February 22, in the Philadelphia General Hospital of cerebral thrombosis and hypertensive cardiovascular disease.

Michael Henry Shea, Fall River, Mass.; College of Physicians and Surgeons, Baltimore, 1900; for many years medical inspector in the public schools; aged 77; died, February 4, of arteriosclerosis, myocarditis and bronchopneumonia.

Edwin Clarence Bliss, Grinnell, Iowa; Rush Medical College, Chicago, 1885; member of the Iowa State Medical Society; aged 79; died, February 26, in Oberlin, Ohio, of mitral stenosis, cardiac enlargement and arteriosclerosis.

George Knowlton Janes, Williamsburg, Kan.; Missouri Medical College, St. Louis, 1884; member of the Kansas Medical Society; formerly many years member of the school board; aged 78; died, February 17, of diabetes mellitus.

Waldo Fisher, Alton, Ill.; Rush Medical College, Chicago, 1882; formerly member of the city council and board of education; for many years on the staff of St. Joseph's Hospital; aged 81; died, February 8, of cerebral sclerosis.

John Percy Nelson ⊕ Beggs, Okla.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904; aged 69; died in February in Okmulgee of streptococcic infection of the nose and throat.

William Henry Rennie, Portage la Prairie, Man., Canada; Trinity Medical College, Toronto, Ont., 1900; president, Council of the College of Physicians and Surgeons of Manitoba; aged 67; died, February 6, of myocarditis.

Hubert C. Hannah ⊕ Junction City, Kan.; Homeopathic Medical College of Missouri, St. Louis, 1897; on the staff of the Junction City Municipal Hospital; aged 64; died, February 14, of a self-inflicted bullet wound.

Edward Arthur Darby, St. Cloud, Minn.; University of Michigan Homeopathic Medical School, Ann Arbor, 1888; Cleveland Medical College, 1891; aged 83; died, February 11, of cerebral hemorrhage and hypertension.

Jesse Dalton Johnston, Emporium, Pa.; Medico-Chirurgical College of Philadelphia, 1910; for many years county coroner; aged 55; died, February 3, of acute cardiac dilatation, coronary thrombosis and myocarditis.

Garland Lightfoot Morriss, Blackstone, Va.; University College of Medicine, Richmond, 1902; member of the Medical Society of Virginia; aged 60; died, February 24, of adenocarcinoma of the stomach and duodenum.

John Morgan Golden, Walnut Grove, Miss.; Memphis (Tenn.) Hospital Medical College, 1891; member of the Mississippi State Medical Association; aged 72; died, February 25, of a self-inflicted bullet wound.

Henry W. Schulz, St. Louis; St. Louis Medical College, 1888; member of the Missouri State Medical Association; aged 70; on the staff of the Lutheran Hospital, where he died, February 10, of heart disease.

Frederick H. Metcalf ⊕ Franklin, Ill.; Chicago Medical College, 1886; aged 76; died, February 20, in Our Saviour's Hospital, Jacksonville, of uremia, following urinary retention due to hypertrophied prostate.

James Franklin Turner Jr., Detroit; University of Arkansas School of Medicine, Little Rock, 1937; aged 23; intern at the Henry Ford Hospital, where he died, February 3, of subacute bacterial endocarditis.

Rigdon H. Slocumb, Maywood, Calif.; University of Nebraska College of Medicine, Omaha, 1924; served during the World War; aged 42; died, February 12, in Huntington Park, Calif., of pneumonia.

Clinton Grant Lumley, Huntington Park, Calif.; Chicago Medical College, 1889; member of the California Medical Association; aged 76; died, February 16, of hypertensive heart disease and diabetes mellitus.

Edward Joseph Walsh, Davenport, Iowa; Bennett College of Eclectic Medicine and Surgery, Chicago, 1890; Rush Medical College, Chicago, 1891; aged 69; died, February 4, of carcinoma of the pancreas and liver.

Don L. Harden, Brownville Junction, Maine; Medical School of Maine, Portland, 1905; aged 59; died, February 4, in the New England Deaconess Hospital, Boston, of hemochromatosis and uremia.

Bird Hagans Miller ⊕ Blockton, Iowa; Marion-Sims College of Medicine, St. Louis, 1893; past president of the Taylor County Medical Society; aged 71; died, February 24, of bronchopneumonia.

Fred A. Seed, Atlanta, Ga.; Homeopathic Medical College of Missouri, St. Louis, 1897; veteran of the Spanish-American War; aged 62; died, February 7, of coronary occlusion and arterial hypertension.

Scott F. Verbeck, Mazomanie, Wis.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1883; formerly member of the state legislature; aged 78; died, February 13, of coronary thrombosis.

William James Sharpe, Toledo, Ohio; McGill University Faculty of Medicine, Montreal, Que., Canada, 1872; aged 87; died, February 4, at his winter home in Delray Beach, Fla., of chronic nephritis.

William H. Hickman, Philadelphia; Jefferson Medical College of Philadelphia, 1881; aged 78; died, February 11, of arteriosclerotic heart disease with auricular fibrillation and cerebral embolism.

Jacob Herman Christman, Los Angeles; Eclectic Medical Institute, Cincinnati, 1903; aged 65; died, February 8, in a local hospital of uremia due to carcinoma of the prostate with urinary retention.

Walter Vander Wilt, Rock Rapids, Iowa; State University of Iowa College of Medicine, Iowa City, 1925; member of the Iowa State Medical Society; aged 40; died, February 7, of lobar pneumonia.

Edward Winslow Taylor, Philadelphia; Jefferson Medical College of Philadelphia, 1881; aged 84; died, February 6, in the Germantown Hospital of prostatic hypertrophy and hypostatic pneumonia.

Martin R. Doyle, East St. Louis, Ill.; Kentucky School of Medicine, Louisville, 1885; aged 83; died, February 5, in St. Mary's Hospital of a large stone in the common bile duct and cholecystitis.

John Walters Cristler, Shippingport, Pa.; Medical College of Ohio, Cincinnati, 1886; member of the Medical Society of the State of Pennsylvania; aged 81; died, February 13, of arteriosclerosis.

William Wiley Stancell, Rockingham, N. C.; University College of Medicine, Richmond, 1906; aged 57; died, February 9, of burns received when his mattress caught fire, presumably from a cigaret.

Florence Quindaro McQuaide ⊕ Philadelphia; Woman's Medical College of Pennsylvania, Philadelphia, 1889; aged 71; died, February 9, in Brigantine Beach, N. J., of arteriosclerotic heart disease.

Edmund William Bolio, Detroit; Detroit College of Medicine, 1893; served during the World War; aged 68; died, February 2, in the Providence Hospital of acute gangrenous appendicitis.

Ralph Emerson Jenkins Le Master, Marion, Ind.; Rush Medical College, Chicago, 1930; member of the Indiana State Medical Association; aged 36; died, February 5, of coronary thrombosis.

Howard Dewey Booth, Charleston, W. Va.; Medical College of Virginia, Richmond, 1938; aged 38; intern at the Charleston General Hospital, where he died, February 10, of peritonitis.

Arthur William Davies, College Springs, Iowa; Northwestern Medical College, St. Joseph, Mo., 1893; aged 77; died, February 4, in the Hand Hospital, Shenandoah, of bronchopneumonia.

John S. Hogshead, Covelo, Calif.; St. Louis College of Physicians and Surgeons, 1899; formerly connected with the Indian Service; aged 76; died, February 15, of coronary occlusion.

Thomas J. Miller, Norwich, Ohio; Columbus Medical College, 1878; Medical College of Ohio, Cincinnati, 1887; aged 89; died, February 5, in New Concord of arteriosclerotic heart disease.

Frank M. Ryan ⊕ Maryville, Mo.; Ensworth Medical College, St. Joseph, Mo., 1892; past president of the Nodaway County Medical Society; aged 69; died, February 19, of heart disease.

Ebberly J. Leigh ⊕ Hiawatha, Kan.; Rush Medical College, Chicago, 1884; past president of the Brown County Medical Society; aged 78; died, February 18, of prostatitis and uremia.

Oliver Archibald Taylor, Cleveland; Meharry Medical College, Nashville, Tenn., 1894; aged 66; died, February 25, in the Mount Sinai Hospital of meningitis and bronchopneumonia.

Joseph Potter Riggs, Milton, N. J.; University of Maryland School of Medicine, Baltimore, 1903; aged 59; died, February 24, in the Franklin (N. J.) Hospital of lobar pneumonia.

George Washington Potter ⊕ Redfield, S. D.; Rush Medical College, Chicago, 1901; on the staff of the Baldwin Community Hospital; aged 64; died, February 15, of bronchopneumonia.

Lee B. Van Camp, Omaha; University of Nebraska College of Medicine, Omaha, 1898; for many years county physician; aged 61; died, February 27, in the Clarkson Hospital of pneumonia.

John Peters Squire, Sherrill, Iowa; St. Louis College of Physicians and Surgeons, 1902; aged 57; died, February 10, in the Mercy Hospital, Dubuque, of carcinoma of the thyroid.

John Ernest Drury, Wenatchee, Wash.; Trinity Medical College, Toronto, Ont., Canada, 1901; aged 64; died, February 7, of hypertensive heart disease and cerebral hemorrhage.

Frederick Hall Corey ⊕ Rockland, Mass.; Tufts College Medical School, Boston, 1904; aged 60; died, February 18, in the Deaconess Hospital, Boston, of hypertensive heart disease.

William Henry Wiley, Clearmont, Mo.; Northwestern Medical College, St. Joseph, 1890; aged 76; died, February 2, of cerebral thrombosis, endocarditis and bronchopneumonia.

Thomas Duff, Wampum, Pa.; Baltimore Medical College, 1911; member of the Medical Society of the State of Pennsylvania; aged 56; died, February 16, of cerebral hemorrhage.

Charles Wittenmyer, Arcanum, Ohio; Detroit Medical College, 1885; aged 81; died, February 7, of influenza, bronchopneumonia and a fractured femur due to a fall on the ice.

Nelson B. Ross, Muncie, Ind.; Medical College of Indiana, Indianapolis, 1895; aged 66; died, February 8, in the Indiana State Prison Hospital, Michigan City, of heart disease.

Virgil Eubank Stiff, Harmony Village, Va.; Medical College of Virginia, Richmond, 1906; aged 62; died, February 11, at the Stuart Circle Hospital, Richmond, of mastoiditis.

Salvatore Schiro, San Francisco; Regia Università degli Studi di Palermo Facoltà di Medicina e Chirurgia, Italy, 1900; aged 62; died, February 1, of poison, self administered.

Kash Stanley Peters, Bethlehem, Pa.; Temple University School of Medicine, Philadelphia, 1935; aged 28; died, February 10, of burns received when his home caught fire.

James Thomas Glass, Clifton, Texas; University of Louisville (Ky.) Medical Department, 1889; aged 81; died, February 7, of chronic cholecystitis and gastro-enteritis.

Karl Waller Smith, Madison, Wis.; Jefferson Medical College of Philadelphia, 1911; served during the World War; aged 59; died, February 13, of cerebral hemorrhage.

Charles E. Bricker, Philadelphia; Jefferson Medical College of Philadelphia, 1880; for many years city police surgeon; aged 83; died, February 16, of bronchopneumonia.

Albert Sidney Beasley Jr., New York; Harvard University Medical School, Boston, 1919; aged 44; died, February 14, in the Mount Sinai Hospital of heart disease.

William A. Welch, Wooster, Ohio; Western Reserve University Medical Department, Cleveland, 1884; aged 77; died, February 2, of uremia and hypostatic pneumonia.

Frank Elmer McClane, St. Petersburg, Fla.; Barnes Medical College, St. Louis, 1895; served during the World War; aged 75; died, February 6, of myocarditis.

Royal Deforest Sykes, Cumberland, Md.; Western Reserve University Medical Department, Cleveland, 1887; aged 72; died, February 2, of chronic myocarditis and nephritis.

Thomas Martin, Washington, D. C.; Howard University College of Medicine, Washington, 1884; aged 83; died, February 15, of chronic nephritis and myocarditis.

James Aloysius Harten, Montowese, Conn.; Baltimore Medical College, 1910; aged 53; died, February 6, of cerebral hemorrhage and arteriosclerotic heart disease.

Harlie V. Lewis, Lawrenceville, Ill.; Physio-Medical College, Cincinnati, 1880; formerly county coroner; aged 80; died, February 11, of cerebral hemorrhage.

Julius Rugg Hamilton, Los Angeles; Medical College of Virginia, Richmond, 1914; served during the World War; aged 51; died, February 5, of coronary occlusion.

Joseph Thomas Gaines, Denver; Kentucky School of Medicine, Louisville, 1893; aged 68; died, February 2, in St. Joseph's Hospital of cerebral hemorrhage.

George McClain Harper, Springfield, Ill.; Medical College of Indiana, Indianapolis, 1897; aged 61; died, February 4, in St. John's Hospital of diabetes mellitus.

Francis Marion Replogle, Los Angeles; Miami Medical College, Cincinnati, 1895; aged 85; died, February 13, of coronary thrombosis and cardiac hypertrophy.

Albert Augustine Judge, Boston; Harvard University Medical School, Boston, 1897; aged 72; died, February 19, of arteriosclerosis and cerebral thrombosis.

John L. Carroll, Asheville, N. C.; Louisville (Ky.) Medical College, 1905; formerly county coroner; aged 69; died, February 7, of gangrenous appendicitis.

George F. Garmier, Hartville, Ohio; Western Reserve University Medical Department, Cleveland, 1896; aged 74; died, February 14, of arteriosclerosis.

Robert Watt Watterson, Darlington, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1889; aged 78; died, February 20, of chronic myocarditis.

Harvey Allen Harding, Amsterdam, Ohio; Starling Medical College, Columbus, 1898; aged 71; died, February 7, at Cadiz of carcinoma of the prostate.

Walter S. Mason, Cambridge, Ohio; Medical College of Ohio, Cincinnati, 1889; aged 74; died, February 14, of chronic myocarditis and paralysis agitans.

Charles Wesley Schaubel ⊕ Philadelphia; Jefferson Medical College of Philadelphia, 1904; aged 56; died, February 25, of chronic interstitial nephritis.

Arthur Alanson Griffis ⊕ Tipton, Iowa; Cleveland Homeopathic Medical College, 1898; aged 77; died, February 10, of carcinoma of the stomach.

James Robert Porter, Washington, D. C.; Howard University College of Medicine, Washington, 1929; aged 42; died, February 10, of pneumonia.

James Putney, Charleston, W. Va.; University of Maryland School of Medicine, Baltimore, 1889; aged 79; died, February 6, of heart disease.

George R. Peckinpaugh, Mount Vernon, Ind.; Medical College of Ohio, Cincinnati, 1882; aged 84; died, February 10, of hypostatic pneumonia.

Almon Dwight Birchard, Cincinnati; Miami Medical College, Cincinnati, 1884; aged 80; died, February 19, of cardiorenal vascular sclerosis.

David C. Shelton, Jasper, Tenn.; University of Nashville Medical Department, 1897; aged 70; died, February 4, of organic heart disease.

Robert Cooper Rasin, Philadelphia; Baltimore University School of Medicine, 1890; aged 76; died, February 5, of acute cardiac dilatation.

James H. Westcott, Utica, N. Y.; Philadelphia University of Medicine and Surgery, 1872; aged 88; died, February 6, of arteriosclerosis.

Frank Nichols Greene, New York; Jefferson Medical College of Philadelphia, 1890; aged 70; died, February 2, of heart disease.

Edward Lorne Jackson, Sierra Madre, Calif.; Manitoba Medical College, Winnipeg, 1896; aged 68; died, February 3, of peritonitis.

Lowndes Hendrick, Brundidge, Ala.; Medical College of Alabama, Mobile, 1890; aged 74; died, February 17, of cerebral hemorrhage.

John Brooks Wertz, Spencer, Iowa; State University of Iowa College of Medicine, Iowa City, 1892; aged 73; died, February 6.

Wilbur Lament Rickard, Brooklyn; Long Island College Hospital, Brooklyn, 1889; aged 71; died, February 15, of pneumonia.

Edward Danby Gibson, Buffalo; University of Buffalo School of Medicine, 1900; aged 61; died, February 10, of heart disease.

Thomas F. Ringle, Tippecanoe, Ind. (licensed in Indiana in 1897); aged 87; died, February 15, of heart disease.

Correspondence

"RELATION OF PHYSICAL EXERTION AND EMOTION TO PRECIPITATION OF CORONARY THROMBI"

To the Editor:—A communication by Drs. Masters, Dack and Jaffe in THE JOURNAL April 22 referring to my paper entitled "Relation of Physical Exertion and Emotion to Precipitation of Coronary Thrombi" in THE JOURNAL March 11 deserves some comment.

I am afraid that your correspondents have missed the main point in my paper. I have shown that the formation of coronary thrombi is gradual, sometimes occupying several days before occlusion with its resulting precordial pain is produced. The onset of precordial pain, then, merely marks the final phase of a process which was initiated (by capillary rupture) some time previously. Therefore the activities of a patient just before the onset of precordial pain, as tabulated in 1,400 cases by your correspondents, are purely coincidental and have no relation to the cause of thrombus precipitation. Their smaller series of 250 cases warrants more attention. I have the greatest respect for the careful study which Masters and his co-workers have given to the case histories in their various series but I submit that no history can adequately cover the numerous emotional shocks that occur to an individual in the course of four weeks. Their finding, therefore, that 250 cases of coronary thrombosis failed to give a history of undue exertion or emotion for a month prior to occlusion must be accepted with reserve. Likewise the statement that their group of forty patients who suffered from carcinoma, heart failure and the like and who were bedridden for weeks or months prior to coronary artery occlusion is open to objection. I should like to know how many of these forty patients suffered from persistent hypertension. Physical exertion in this small series is ruled out, but can the fear of death, the fear of operation, the presence of nightmares and the like, all of which may produce transient hypertension, be eliminated?

In my paper I did not "categorically state that coronary thrombi are precipitated by exertion and emotion." I suggested, rather, that "high coronary blood pressure, the result of strenuous exertion or emotion (or of persistent hypertension) is one of the underlying causes of capillary rupture and intimal hemorrhage in arteriosclerotic coronary arteries." Obviously there are other factors that may produce intimal hemorrhages, and these I have described in detail in previous papers. Included among these other factors are softening by atheroma of the stroma supporting the capillary, and also various conditions that may increase capillary fragility, such as old age and local inflammatory processes. Vitamin deficiency also may render intimal capillaries more fragile.

Your correspondents state that I have given purely theoretical arguments but neither pathologic nor clinical evidence to show that hypertension, persistent or transient, can produce subintimal hemorrhage and resulting coronary thrombosis. May I repeat the pathologic evidence, much of which has already been included in my previous papers? 1. Clark (*Ann. Int. Med.* **9**:1043 [Feb.] 1936) found that young capillaries in the rabbit's ear, as observed through a transparent chamber, were readily dilated and ruptured by slight external pressure or by increased blood pressure. 2. Cutter and Marquardt (*Proc. Soc. Exper. Biol. & Med.* **28**:113 [Nov.] 1930), on exerting negative external pressure on the capillaries of the skin, found that rupture occurred at lower negative pressures in persons with hypertension (200 mm. plus) than in those with normal pressures. 3. I have already remarked on the fact that intimal capillaries are usually of normal caliber when seen in the denser intimal layers, while they are frequently dilated in areas of atheroma and as they penetrate intimal hemorrhages. This dilatation must obviously be due in part to pressure within the capillaries. Wartman, a pathologist (*Am. Heart J.* **15**:459 [April] 1938), remarks: "It is easy to conceive that capillaries within an atheromatous plaque may rupture, for the soft, easily compressible material of the atheroma offers no support against the capillary blood pressure. Since patients with coronary arteriosclerosis frequently have hypertension, a small intramural capillary might readily be ruptured and form a hematoma." Pathologists do not often agree thus. If persistent hypertension can result in capillary dilatation and rupture, as the foregoing evidence suggests, will not transient hypertension due to excessive exercise or emotion produce the same effect?

I was interested to note that your correspondents agree that coronary thrombosis is usually associated with subintimal hemorrhage. May I state here that I did not "corroborate" any one's work in connection with these lesions. I discovered and described intimal hemorrhages due to capillary rupture and showed their relation to coronary thrombosis (*Arch. Path.* **22**:313 [Sept.] 1936).

J. C. PATERSON, M.D., Ottawa, Canada.

AMPHETAMINE IN CHRONIC ALCOHOLISM

To the Editor:—The reply which recently appeared in *Queries and Minor Notes* to a letter relative to the use of amphetamine (benzedrine) in the treatment of chronic alcoholism as recommended by Dr. Wilfred Bloomberg might easily give rise to a regrettable misunderstanding. Dr. Bloomberg made the suggestion only after long experience with the drug in other conditions, for he (with Prinzmetal) was the first to report its effectiveness in the treatment of narcolepsy. He has further, in preparation, a detailed study of the effects of large doses given over a period of three years to some of his early patients and a careful survey of all the cases in which ill effects are reported to have followed the use of the drug. This study has led him to the belief that its use under medical supervision is entirely justified when dealing with such serious diseases as narcolepsy and chronic alcoholism.

The merits of the treatment should certainly not be judged from the much garbled press report, for which Dr. Bloomberg was not responsible. Those who are interested in the subject should by all means read his conservative and well documented article in the *New England Journal of Medicine* (**220**:129 [Jan. 26] 1939).

As one who has watched the progress of the work and referred some of the patients to him, I can give testimony that he has understated rather than overstated his case.

TRACY J. PUTNAM, M.D.,
Harvard Medical School,
Boston.

TELEPHONE DIRECTORIES IN THE MOUNTAIN STATES

To the Editor:—In the March 25 issue of THE JOURNAL was an editorial comment regarding "Florida Telephone Directories" whereby the users of Florida telephone directories published by the Southern Bell Telegraph and Telephone Company may know whether a person listed therein as a doctor is a doctor of medicine, an osteopath, a chiropractor, a naturopath or a practitioner of some other method of healing.

I have made an investigation of the situation here in Arizona as relates to the foregoing and I find that the Mountain States Telephone and Telegraph Company has since November 1920 been adhering to this policy, and I think it only fair to this company that proper credit be given it for its cooperation.

CHARLES S. SMITH, M.D., Nogales, Ariz.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

CENTRAL NERVOUS SYSTEM SYPHILIS

To the Editor:—Have you any information regarding the effect of mapharsen on syphilis of the central nervous system following spinal drainage that would fix it in the nerve centers and cause paralysis? A white man aged 38 came down two years ago with partial paralysis of the left arm and leg and responded to oral medication in the form of drops—probably potassium iodide. A routine examination required by his employers revealed strongly positive Wassermann and Kahn reactions. The treatment consisted of four injections of neoarsphenamine four days apart in ascending doses, 0.15, 0.2, 0.3 and 0.6 Gm., biweekly administration of bismuth preparations, six injections of 1.5 per cent and nine injections of 3 per cent, and eleven injections of mapharsen, 0.04 Gm. once a week with a total of four neoarsphenamine, eleven mapharsen and fifteen bismuth injections between Sept. 8 and Dec. 20, 1938. At this point malaria was urged as the next therapeutic step. The patient thought this a drastic measure and consulted me. He states that he never had venereal infection or any previous treatment except as outlined. He is married and has three apparently healthy children, 6, 4 and 2 years of age. His wife's blood has been negative on two occasions to Wassermann, Kahn and Kline tests. My examinations were negative except for weakness of the left arm and leg and loss of the reflexes. The blood and spinal fluid gave positive Kahn and Kline reactions. The spinal fluid cell count was 50, globulin a trace and colloidal gold curve 0002210000. I advised spinal drainage, oral potassium iodide and intravenous injections of neoarsphenamine. From my readings I learn that malaria should be tried after other therapy fails in syphilis of the central nervous system, that it works best in dementia paralytica and tabes, and that reversal of the spinal fluid reaction is only about 2 per cent after the first year and 4 per cent after the tenth year. This case was one of the meningovascular type. My first treatment was 0.6 Gm. of neoarsphenamine intravenously and under local anesthesia a complete spinal drainage. These treatments were given at weekly intervals, the patient remaining in bed a full day and returning to his regular occupation the following day. Eight of these were given. After the third treatment a decided improvement followed, the patient stating that his left arm and leg were as good as ever and that his entire outlook on life was brighter. His wife also noticed the change. On the ninth injection I decided to change to mapharsen because of the reversals in the reaction reported in the literature. Mapharsen had previously given him pain along the vein. I injected it rapidly as advised and still the pain developed. A spinal drainage was done under local anesthesia as on eight previous occasions. The following day he said his back was sore and three days after he had retention of urine. On examination there were no new developments except that the prostate was soft, soggy and tender. By massage I expressed a great deal of thick, yellow pus. Almost instantly after the massage he said that his back was much better and he walked about without pain. His retention followed a chill and a rise in temperature to 102 F. The retention persisted and had to be relieved by catheter. He looked as if he had typhoid and was hospitalized. Agglutination tests were negative for typhoid, paratyphoid A and B and undulant fever. Except for a white count of 32,000, other laboratory data were negative. His neck was stiff and advanced Kernig's sign was present on admission. Five days after treatment the spinal tap was dry even with a large caliber needle and suction with a syringe. His abdomen was distended and tympanitic and retention persisted. He died with the temperature going to the ceiling and without an autopsy. I believe that he died of toxemia resulting from intestinal paresis and I hasten to inquire whether the change to mapharsen had anything to do with it. Was I justified in advising against malaria and my recommendations? How do you account for the negative reaction of his wife? Should serologic study be done on children?

M.D., Ohio.

ANSWER.—Considering the information submitted, it would seem that from the theoretical standpoint at least this case of central nervous system syphilis was well and intelligently handled. Without a necropsy it is impossible to state what was the most likely cause of death. There is no reason to think that mapharsen as such was a direct contributory factor. Therapeutic shock (Herxheimer reaction) and therapeutic paradox likewise seem unlikely, considering the amount of antecedent therapy. Hemorrhagic encephalitis, sometimes a complication of arsenical therapy of syphilis, might give a clinical picture similar to the one described. It is unusual for such a reaction to occur so late in the arsenical course. It characteristically follows the first three or four weeks of treatment. Under any circumstance a critical review of the technic employed in the spinal puncture and drainage procedure would seem indicated, though, in the hands of an experienced operator, hardly necessary.

It is not uncommon to find a negative blood serologic test on the wife of a patient with late central nervous system syphilis. There are, of course, several possibilities under the circumstances: first, that the wife has not been infected because sexual union occurred after the husband had reached a late and relatively noninfectious stage of his disease; secondly, that the woman has had syphilis of long duration and has become seronegative either with or without treatment.

Since the children for all practical purposes are always infected by the mother, if it can be certain from the clinical standpoint that the mother is not syphilitic there is no indication to study the children for the disease. If, on the other hand, it is not possible to determine whether the woman is in actuality seronegatively syphilitic, it would be advisable to study the children in an effort to determine whether they are diseased.

POSSIBLE THROMBOSIS OF THE BRACHIAL ARTERY

To the Editor:—A man aged 72, with acknowledged arteriosclerosis, struggled quite violently to close a large double door. During the exertion he experienced a sharp pain in his hand and arm. The pain continued, gradually becoming worse. He stated that his hand and arm became cold and chalklike. When pain became so severe in from thirty-six to forty-eight hours a physician was consulted, and eventually amputation was done. A diagnosis of occlusion of the brachial artery was made but no effort was made to locate the presence of an embolus or thrombus. I should like to know whether severe exertion and local muscular activity could so injure the brachial artery already diseased that occlusion resulted.

JAMES J. HENNESSY, M.D., Hartford, Conn.

ANSWER.—It is possible that exertion may produce local injury to an artery so that it becomes thrombosed. Arterial thrombosis following exertion must occur relatively uncommonly, but in the past few years two patients have been examined whose histories are straightforward examples of sudden arterial occlusion of the arteries of the legs occurring during or following exertion. The exact mechanism is not known but probably an atherosclerotic plaque breaks loose from the intima, protrudes into the lumen of the artery and forms the basis for a thrombus. Insufficient evidence is given in the inquiry to determine whether the diagnosis of arterial thrombosis was correct. Was axillary thrombophlebitis caused by effort considered (Matas, Rudolph: *Am. J. Surg.* **24**:642-666 [June] 1934)? If there was arterial thrombosis, there should have been evidence of impaired circulation such as absence of pulsations in the brachial, radial and ulnar arteries or an abnormal pallor of the hand with elevation and abnormal rubor with dependency. The diagnosis could have been substantiated or disproved by examination of the amputated limb or by observation of the arteries by the surgeon at the time of amputation. Necessity for amputation of an arm because of arterial thrombosis occurs rarely. The upper extremity recovers from the consequences of arterial thrombosis much more commonly than does the lower extremity. A summary answer can be stated as follows: Arterial thrombosis could have resulted from effort in the instance described by the inquirer, but a diagnosis of arterial thrombosis cannot be made on the basis of the information given.

RECURRENT HERPES SIMPLEX

To the Editor:—A man has had recurrent impetigo on the lower part of the chin several times a year for the last three years. It begins in the same spot and subsides with treatment. Is this unusual and how would you prevent the recurrence of the condition?

M.D., Massachusetts.

ANSWER.—A vesicular eruption recurring in the same place several times a year is not impetigo but recurrent herpes simplex. There are several methods of treatment more or less successful in preventing recurrence of this disorder. The administration of calcium in large doses, autogenous injections of blood or serum and ultraviolet treatment have all been recommended.

Because of the fact that herpes is one of the diseases caused by a virus and the viruses seem to have some relation one to the other, cowpox vaccine has been used to treat herpes with some success in ameliorating and postponing the attacks. More effective is vaccination with the contents of the patient's own vesicles. Schmidt (Vaccination for Herpes, *Arch. Dermat. & Syph.* **32**:106 [July] 1935) used this method, originated by Plesch, on four patients, and all of them reacted with local redness and slight swelling. One had slight chilliness and nausea for a short time. Two of the four have had no recurrence of the herpes since the vaccination. The other two required a second vaccination and have remained well since.

In a recent article, Hall (Radiation Treatment of Herpes Simplex, *Am. J. Roentgenol.* **39**:393 [March] 1938) reports excellent results from 375 roentgens of unfiltered x-rays, which cause immediate relief of discomfort and rapid resolution of the inflammation. This is a full erythema dose. He also states that he treated four patients with only 120 to 137 roentgens

filtered through 1 mm. of aluminum with excellent results. Others have reported success with this method. Hall quotes Milian's statement that it may be necessary to repeat the treatment as many as four times at intervals of a month to prevent recurrence. If the smaller dose of filtered rays proves as effective as the larger one of unfiltered rays, it would seem preferable in view of the possible necessity of repeating the treatment several times.

DEPILATORIES

To the Editor:—May I have information concerning the relative effectiveness and local irritant action of barium, calcium, sodium and stannous sulfides as depilatories? Please furnish me with sources of information available in the English language. Are there other substances more desirable than the sulfides? I have already consulted the publication entitled "Cosmetics and Allied Preparations."

KARL E. MORRIS, M.D., Rahway, N. J.

ANSWER.—Sodium sulfide, the most soluble of these preparations, is likely to be the most irritating and can be considered only for the preparation of a liquid depilatory. Since the barium ions are toxic, their employment is actually prohibited in certain countries (Germany). Stannous sulfide has not come into general use. It requires a stabilizer. The following formula (from Volk, R., and Winter, F.: Lexikon der kosmetischen Praxis, Vienna, Julius Springer, 1936) is used by some dermatologists:

	Mild	Strong
Strontium sulfide, Gm.	80.0	80.0
Zinc oxide, Gm.	125.0	40.0
Starch, Gm.	150.0	40.0
Menthol, Gm.	1.0	0.6

Mix with water into a thick paste. Apply a moderately thick layer with a wooden spatula, scrape off after from five to seven minutes, rinse off with liberal use of water, apply 0.5 per cent citric acid solution to neutralize the alkali, dry and apply cold cream and finally talcum. Frequent and liberal use of solution of hydrogen peroxide not only bleaches hair but also makes it brittle and is thus in a sense epilating. Rubbing the part, liberally soaped, twice a day with pumice stone removes hair in the course of from one to six months.

METABOLISM OF XANTHINES

To the Editor:—A careful search through the literature has not revealed satisfactory answers for the following questions: Is there any information concerning the chemistry of aminophylline during its passage through the body? In what final form is aminophylline excreted in the urine and elsewhere? Might it have any influence on the production of uric acid stones? Might the dehydratoin with ammonium chloride, mercupurin or fluid restriction have any effect on the formation of uric acid stones in a case of myocardial insufficiency? I would greatly appreciate an answer to each of these questions unobtainable elsewhere. M.D., New York.

ANSWER.—The question of the influence of the ingestion of the methylated xanthines, 1,3,7-trimethyl xanthine (caffeine), 3,7-dimethyl xanthine (theobromine) and 1,3 dimethyl xanthine (theophylline) on the excretion of uric acid has been carefully studied in the human subject by Myers and Wardell (*J. Biol. Chem.* **77**:697 [May] 1928) and in the Dalmatian coach dog, which resembles man in its purine metabolism, by Hanzal (Dissertation, Western Reserve University, 1930). Aminophylline is a double salt or mixture of theophylline and ethylenediamine, containing not less than 70 per cent of theophylline, and is much more soluble than the free xanthine. Theophylline in this form was employed by Myers and Wardell in their experiments. These authors found about a 10 per cent increase in the excretion of uric acid after the ingestion of theophylline, although this represented somewhat less than 10 per cent of the theophylline ingested. In one of their series of experiments the uric acid was estimated by isolation and weighing, the figures checking closely the results obtained by two colorimetric methods. It seems fairly certain, therefore, that there is a small increase in the excretion of uric acid after the ingestion of aminophylline. It is difficult to say whether this increased excretion of uric acid is due to demethylation of this xanthine or is the result of a slight stimulation of metabolism. It is a well known fact that caffeine slightly increases the basal metabolism (about 5 per cent), and Myers and Wardell and others have found an increased excretion of uric acid after the ingestion of caffeine. There is one other complicating factor in the case of theophylline (1,3 dimethyl xanthine) that must be considered: 1,3 dimethyl uric acid gives the color reaction for uric acid and might be formed from theophylline by oxidation of the number 8 carbon. As Myers and Hanzal (*Am. J. Physiol.* **99**:458 [Oct.] 1929; *J. Biol. Chem.* **97**:lxix [July] 1932) have observed, this does appear to occur to a slight extent. In the case of caffeine and theobromine, Myers and Wardell determined the urinary excretion of purine base nitrogen after the ingestion of these two methylated xanthines and found that this was roughly equivalent to about 15 per cent of the amount ingested. The same would probably be true of theophylline.

If one considers the amount of extra uric acid excreted (about 10 per cent) as derived from theophylline by demethylation and oxidation, together with the increased excretion of purine base nitrogen, it is possible to account for only about 25 per cent of the theophylline ingested.

It seems doubtful, from the slight increase in uric acid excreted, that aminophylline could have any significant influence on the formation of uric acid calculi. It would probably have less influence than the liberal use of coffee (Mendel, L. B., and Wardell, Emma L.: Effect of Ingestion of Coffee, Tea and Caffeine on the Excretion of Uric Acid in Man, THE JOURNAL, June 16, 1937, p. 1805). From the information which is available in the literature it appears improbable that dehydration with ammonium chloride, mercupurin or fluid restrictions should lead to the formation of uric acid stones in myocardial insufficiency. Although the solubility of uric acid in the urine would be decreased by the increased urinary acidity resulting from the administration of ammonium chloride and there might be some increase in the formation of uric acid owing to the mercupurin therapy, this would probably be fully compensated for by the diuresis.

UNILATERAL VENOUS ENGORGEMENT IN TUBERCULOSIS

To the Editor:—A patient with long-standing skeletal tuberculosis has, since the appearance of amyloidosis (with markedly enlarged spleen and liver) a year ago, persistently shown dilated veins distinctly limited to the left half of the trunk. Can any anatomic explanation be offered for this distribution of distended veins? M.D., New York.

ANSWER.—The superficial veins of the thorax near the medial line drain into the internal mammary, the superior epigastric and the anterior intercostal vein. The latter two veins are tributaries to the internal mammary. From the side of the chest the lateral thoracic vein and the costo-axillary vein receive numerous tributaries before draining into the axillary vein. The azygos vein is a continuation upward of the ascending lumbar vein and lies on the right side of the front of the bodies of the thoracic vertebrae. At the level of the fourth thoracic vertebra it curves forward and enters the superior vena cava. It receives the intercostal veins of the right side with the exception of the first two or three, which join into a common trunk before entering the azygos vein. This vein has an anastomosis with the inferior vena cava and through the ascending lumbar vein connects with the iliac vein. This is an important communication in case of obstruction of the vena cava.

On the left, lying along the sides of the thoracic vertebrae, is the hemiazygos vein, which is a continuation upward of the ascending lumbar vein. At the level of the eighth or ninth thoracic vertebra it crosses to the right side and drains into the azygos vein. Four or five of the left lower intercostal veins are tributary to the hemiazygos vein. The left superior intercostal vein is formed by the joining of the second, third and fourth intercostals. This vein drains into the left innominate vein. However, at its lower end it frequently communicates with the accessory hemiazygos vein, which lies in the posterior mediastinum to the left of the fifth, sixth, seventh and eighth thoracic vertebrae. The accessory hemiazygos vein may either join the hemiazygos or pass across the seventh or eighth thoracic vertebrae to join the azygos vein. The fourth to the eighth intercostal veins on the left side are tributary to the accessory hemiazygos vein.

The superficial veins of the lumbar region communicate freely with the intercostal and lumbar veins through the dorsal and lateral perforating branches. Over the lower part of the anterior and lateral surfaces of the abdomen, the superficial epigastric and the superficial circumflex iliac veins drain blood into the great saphenous vein, which in turn is tributary to the femoral vein. The thoraco-epigastric vein joins with the superficial epigastric vein below and the superficial thoracic veins above. The valves of the thoraco-epigastric vein direct the blood downward below and upward above. However, the valves may be rendered incompetent when the vessel becomes enlarged. Thus there is free communication between the superficial veins of the thorax and those of the abdomen. The thoraco-epigastric vein communicates with the portal system in the region of the umbilicus through a vein in the round ligament. The parumbilical veins, which pass along the ligamentum teres to the abdominal wall, are spoken of as accessory portal veins, since they anastomose with superior and inferior superficial epigastric veins. Thus blood returning from the spleen and the abdominal part of the digestive tract ordinarily passes through the liver capillaries before reaching the heart. In certain diseases of the liver, however, which obliterate many capillaries so that the

blood flow is obstructed, it is only through the anastomoses between the portal system and the superficial veins of the abdomen in the region of the umbilicus that the return flow of blood is possible. In this event, because of the large volume of blood passing through the superficial veins of the abdomen, they become distended and the valves in the thoraco-epigastric become incompetent. Thus blood from the superficial epigastric veins flows freely into the superficial thoracic veins and back to the heart through the internal mammary, the axillary or even the axygos, hemiazygos and accessory hemiazygos veins. Again, obstruction of the inferior vena cava or its tributaries as low as the entrance of the saphenous into the femoral vein may result in marked enlargement of the superficial epigastric and superficial circumflex iliac veins, which in turn, through their free communication, results in enlargement of the superficial veins of the thorax. In this event, blood returns to the heart from the lower extremities through the superficial veins of the abdomen and the thorax.

In the case described in the question it is possible that the enlargement of the spleen is sufficient to cause enough pressure on the tributaries of the hemiazygos vein or this vein itself to obstruct the flow of blood toward the superior vena cava and thus dam back the blood in the tributaries which communicate freely with the superficial veins of the abdomen and thorax. It is also possible that pressure on the ascending lumbar vein or even on the iliac or femoral vein, even from a psoas abscess, would direct the flow of blood returning to the heart by way of the hemiazygos or the inferior vena cava to the superficial veins of the abdomen and thorax.

Although amyloidosis usually does not result in obstruction of the flow of portal blood through the liver, there may be enough associated cirrhosis to offer such obstruction. In this event the blood from the portal system would find its way through the parumbilical veins to the superficial veins of the abdomen and thorax. One would expect that there would be equal dilatation of the superficial veins on the two sides of the body. However, because of anatomic variations it is possible that the parumbilical veins anastomosing with the superficial veins on the left side are better developed than those on the right side. Again, the superficial veins of the abdomen and thorax may lie more deeply on the right side, so that they are not visible from the surface.

PREMATURE ORGASM AND TESTOSTERONE PROPIONATE

To the Editor:—A white man aged 26 complains chiefly of premature orgasm. He is in excellent health, is 5 feet 9 inches (175 cm.) tall and weighs 135 pounds (61 Kg.). He is of slight build, has a high pitched voice and has no hair on the chest. The genitalia are normal and the pubic hair is of normal distribution. Results of all laboratory work have been negative. Libido is normal or slightly above normal. Erection is normal and the only complaint is that already mentioned. Some authorities seem to consider this a form of impotence, and with the good results reported in the use of testosterone propionate in impotence I should like to know what you think of the use of this agent in such a case. Could any ill effects come from the use of this agent in a mature adult? If it is recommended, what dosage would you suggest? This patient has not responded to such treatment as prostatic massage, passage of sounds or instillation of mild silver nitrate.

M.D., Kentucky.

ANSWER.—In every case of premature orgasm, exact diagnosis must precede scientific treatment. One must know whether the condition is due to a congested prostate or prostatic urethra or to a weakness of the sexual muscles or to those surrounding the veins of the penis.

Although testosterone propionate would have no ill effect, it would in all probability have no beneficial effect either. Its use in establishing normal sexual activity is indicated only in those conditions which have definite testicular deficiency. It is of no value in psychic disturbances other than on a suggestive basis. A recent report on the status of testosterone propionate appeared in THE JOURNAL, May 13, 1939.

ANTICOAGULANTS DO NOT INTERFERE WITH BLOOD TYPING

To the Editor:—Can you tell me whether or not the citrating of blood would interfere with its use in typing and cross matching? This problem comes up for consideration in connection with blood banking. Does the presence of citrate in serum or saline suspension of cells interfere with cross matching?

ROBERT S. SMITH, M.D., Boise, Idaho.

ANSWER.—The addition of anticoagulants, such as sodium citrate and potassium oxalate, does not interfere with the use of blood for grouping and cross matching tests. This procedure is followed as a routine in many institutions when collecting samples of blood for grouping tests before a transfusion.

HIPPURIC ACID TEST OF LIVER FUNCTION

To the Editor:—A question has been raised as to the toxic effect on the liver cells of sodium benzoate, which is used (orally) in performing the so-called hippuric acid synthesis test for liver function, as worked out by Armand J. Quick. If this chemical is toxic to the liver cells in the doses recommended by this author, the test would logically be unsuitable in those cases of hepatic disease in which the test is particularly desired. What is the action of sodium benzoate (in doses used by Quick) on the liver cells?

KATSUJI KATO, M.D., Chicago.

ANSWER.—There is no direct or indirect evidence to indicate that sodium benzoate has any toxic effect on the liver.

The drug was formerly used in the treatment of rheumatic disease and has been given to human beings in doses as large as from 25 to 60 Gm. a day without producing any harmful effect. Quick's hippuric acid test has been performed on many patients with extreme degrees of injury to the liver without any appreciable toxic effects or without depressing other hepatic functions; slight gastric irritation has been noted in a few cases, but these symptoms are of a temporary nature. Because of the vulnerability of the diseased liver to hepatotoxic agents, it seems clear that if sodium benzoate had any untoward effect on the liver it could be easily demonstrated in such patients.

One may safely conclude that the administration of a single dose of sodium benzoate for testing hepatic function would have no effect on the liver cells which would interfere in any way with the validity of the hippuric acid test.

PROBABLE DERMATITIS FACTITIA

To the Editor:—A white woman aged 24, married, injured her knee nine years ago. The wound would not heal, although no infection was present. It finally healed after a skin flap operation was performed. Four years later she injured her back, and a section of the sacrum was removed. At this time it was noted that the skin would "crack," i. e. at first a fine red line would appear followed almost immediately by separation of the skin and subsequent bleeding, which was controlled by means of a skin clamp. The condition cleared and did not recur until the patient became pregnant one year later. A therapeutic abortion was performed at four months and the condition was again relieved. During the winter months of that year she had three such attacks, all of which seemed to be controlled by blood transfusions. Later a hysterectomy was performed and she had complete relief until nine months ago, at which time she fell downstairs and almost immediately the condition appeared again and has recurred every two months since this last accident. I have seen only the last three attacks, but they follow a definite course of events at each attack: there is a prodromal feeling of malaise and generalized pains, then nervousness followed by a feeling of extreme weakness. The skin is then affected with the initial lesion, beginning in an abdominal scar. At first it was believed that these lesions might be self inflicted, but on one occasion I noted that a thin red line appeared about 1 inch long and almost immediately began to separate and then began to bleed. At each attack anywhere from ten to thirty cracks may appear. After the attack the patient appears normal in every respect and the wounds heal by first intention. The patient has been given almost every known sedative; she has been given spleen extract, theelin and numerous other endocrine preparations. Blood transfusions at first ended the attacks but lately these have proved useless. The only effective treatment now seems to be complete surgical anesthesia, which has proved successful in the last three attacks. On numerous occasions the Wassermann reaction has been negative. Clotting and bleeding time are always within normal limits. The blood count has shown a gradual drop (the last count shows red cells 3,600,000, hemoglobin 70 per cent). The white count is consistently around 10,000. The differential count shows polymorphonuclear leukocytes 78 per cent, small lymphocytes 19 per cent, large lymphocytes 3 per cent. A sister died from sarcoma involving the colon. This patient has been admitted to many hospitals and has been seen by many specialists in the various branches of medicine. The literature has been searched but no similar case has been found. The diagnosis remains "skin cracking." I should like to know whether any other such case has been reported and if so what diagnosis was made and what treatment was suggested.

M.D., Pennsylvania.

ANSWER.—The occurrence of these attacks after injury and during pregnancy, the prodromes of malaise, pains, nervousness and weakness, temporary relief by surgical operation, therapeutic abortion under general anesthesia, the onset of lesions in a scar and their linear configuration are all typical of hysteria and the self-inflicted lesions often seen in victims of this disease. The suspicion that the lesions might be those of dermatitis factitia were well founded and should lead to a neurologic investigation. His statement that he watched a lesion as it developed is not wholly convincing to those who have studied such cases and know what remarkable cunning these patients possess. Is the physician sure that his attention was not diverted for a short time during the period of observation? It may be that hysteria is capable of causing spontaneous changes in the skin, for it is well known that anesthesia of the skin over large areas can be caused, and it is said that such areas do not bleed as readily as the normal skin. No convincing proof of such a possibility has been given, while the cases of self infliction by hysterical patients are common.

The linear shape of the lesions in this case suggest the dermatitis dysmenorrheica of Matzenauer and Polland, an eruption occurring at or near the menstrual period of women with dysmenorrhea. Many dermatologists, because of the resemblance of the lesions to those of dermatitis factitia, reject the theory of these writers, but Wise and Parkhurst, who studied a patient with such an eruption, believe that it is not self inflicted and think that hysteria was ruled out in their case. They also stress the careful and painstaking study of Matzenauer and Polland (Wise, Fred, and Parkhurst, H. J.: So-Called Dermatitis Dysmenorrheica, *Arch. Dermat. & Syph.* **2**:725 [Dec.] 1920).

If a careful study such as was made by the authors mentioned reveals no evidence that the eruption described in the query is self inflicted, the case should be reported in detail, for it is unique. At any rate the patient should be treated by a capable psychiatrist.

PAIN IN THE GLANS PENIS

To the Editor:—A well developed man aged 33 is normal in every respect except that on erection of the penis there is pain in the distal end of the glans penis which is so severe that the act of coitus cannot be completed. He explains the feeling as a "shortness of the muscles, as a stretching or pulling." He has been married for twelve years, is the father of two children, has enjoyed relations with his wife up to three and one half months ago, has had no illicit relations or intercourse and has never had gonorrhea. He has no discharge, swelling, sore or erythema now. The penis appears to be normal when flaccid and on erection. The prostate is normal in size and not tender. Physical examination is negative. He is mentally well and his wife is well. His business is good; he is not greatly worried except about this pain in the glans. Another way he explains this pain is "as after having coitus with a virgin, but the only difference is that there is no pain except on erection and is worse or aggravated by intercourse." He has had coitus with his wife two or three times a week regularly up to three and one half months ago. Furthermore, he still has the desire but as soon as erection occurs he has the pain and on entering pain is aggravated and coitus must cease and the act cannot be completed. His wife states that it is not in the least painful to her. I am at a complete loss as to the cause and as to treatment.

M.D., Texas.

ANSWER.—There are several possibilities to consider; first and foremost is the possibility that this man has a cavernitis; hence when the penis is engorged and erection takes place there is pulling and pain. One is justified in assuming such to be the case by the statement that the patient explained the feeling as a "shortness of the muscles." On the other hand, painful erections in an occasional case are due to other than inflammatory induration, such as induration due to leukemia. It will hence be necessary to look the patient over not only for local causes but for general causes. Some psychic problem or conflict must also be considered.

In summing up, the patient should have a complete physical examination, including complete studies of the blood as well as an attempt to determine the presence or absence of changes in the penis. If all of these examinations are negative he should have a neurologic examination. Of course if his trouble is due to an inflammatory condition such as a cavernitis the use of heat in the form of hot soaking and hot applications and the internal administration of potassium iodide are indicated. For the present he should refrain from sexual intercourse. On the other hand, if his difficulty is due to leukemia the treatment must be directed toward the leukemia and not toward the local condition. Finally, if this is on a neurologic or psychologic basis the treatment becomes self evident.

EFFECT ON DONOR OF BLOOD TRANSFUSIONS

To the Editor:—Could you give me any information you may have or any references in the literature touching on whether or not a donor giving his blood for transfusions is apt to suffer any acute or permanently bad results to his own health? I recall having read that such donors may complain of serious involvement of the liver or other organs. I do not believe that any person can give up a pint or more of his circulating blood without some latent consequence.

B. F. GALLANT, M.D., Long Island, N. Y.

ANSWER.—There has been no report in the literature concerning any permanently bad results to the health of persons giving blood for transfusions, provided this is not carried out to excess. Before there was better regulation of donors it was not uncommon to encounter donors with more severe anemias than the patient receiving the transfusion, and there can hardly be any doubt that this must have been detrimental to the general health of the donor. However, for most healthy adult male donors the withdrawal of from 400 to 500 cc. of blood every four to five weeks is apparently perfectly harmless. When large amounts (1,000 cc. or more) are rapidly drawn off at one time the donor may feel faint after the transfusion, but usually this sensation will pass off if he is kept lying down for from thirty to sixty minutes following phlebotomy. A rather common after-effect is one more of a psychic nature, and this occurs particularly with inexperienced donors and may follow an ordinary venipuncture or even a puncture of the finger as well as phlebotomy. Susceptible persons may suddenly go into partial or complete collapse, and at times it may be difficult to revive them. Donors experiencing such fainting spells may feel ill for several days after the venipuncture or phlebotomy, but there is apparently no permanent damage. One case has been reported of the death of a donor following a transfusion. It seems that after leaving the operating room the donor fainted and his head struck a concrete floor. The donor got up and went home, where he died of a fractured skull with intracranial hemorrhage.

BRONCHOGENIC CARCINOMAS

To the Editor:—What percentage of primary carcinoma of the lung has been recognized during the last five years? Has any etiology been definitely or even tentatively established, such as irritation from inhalation of dust emanating from tarvia highways? What are the usual clinical course, predominating symptoms, sites of metastasis and the like of that disease? Is hay fever (pollen sensitivity) a predisposing factor?

CLARENCE R. MORSS, M.D., Zumbrota, Minn.

ANSWER.—Somewhat more than 50 per cent of bronchogenic carcinomas have been recognized ante mortem in recent years. No definite cause is known, but as associated factors mechanical, infectious and chemical irritants seem to have a role. However, a definite relation to chemical irritation has not been established. Allergic disease is not known as a predisposing factor. The predominating symptoms are pain in the chest, dry cough, hemoptysis and loss of weight and vitality, but often the symptoms from metastases, depending on their location, overshadow those from the primary tumor. Metastases develop most frequently in the lymph nodes, liver, brain, adrenals and bones. Atelectasis of parts of the lung, caused by bronchial occlusion and frequently resulting in pulmonary abscess, changes the clinical course unfavorably. The duration of the disease from the time of diagnosis ranges from weeks to a few months and occasionally is several years. The only reliable cure has so far been found in surgical removal of the involved lung followed by high voltage roentgen therapy. Radiation therapy alone may have a palliative effect but is not curative.

CONTROL OF SMOKING HABIT

To the Editor:—Can you furnish me with a prescription for a pleasant, nonirritating, nonstaining mouth wash which may be used to remove the desire for tobacco when such a desire is present? Kindly omit name and address.

M.D., California.

ANSWER.—The "desire for tobacco" may be treated by the substitution of some other material which will produce actual unpleasant sensations whenever the tobacco is used, or by inhibition, persuading the subject of the reason for discontinuing the habit and hence developing opposing desires to counteract the one for tobacco. Substitutes such as chewing gum, gentian or chamomile roots, smoking nontobacco materials such as cubebs (no truly denicotinized tobacco product is yet available) and the like may replace the physical motor activity and even the immediate sensations of smoking but are generally ineffective for those desiring the effect of smoking. Lobelia, or lobeline sulfate, a common constituent of advertised "tobacco cures," produces pharmacologic effects similar to those of nicotine and has therefore been recommended as a substitute, but it often produces gastrointestinal symptoms and only temporary cessation of the desire by replacement, which is hardly advantageous.

The best known antagonist consists of the application of a 1 per cent solution of silver nitrate to the postpharynx or the use of a more dilute solution (a 0.5 per cent) as a mouth wash after meals. This results in a highly disagreeable taste whenever the subject attempts to smoke, which in that way tends to overcome the desire. The use of weaker silver solutions or a mild protein silver may be less unpleasant, less irritating and less staining at the time of application but it will be ineffective unless the attempt to smoke results in the unpleasant irritating sensation.

The production of anosmia by the application of zinc sulfate or similar agents to the olfactory mucous membrane and similar interferences with the sense of taste may diminish the enjoyment from smoking tobacco similar to the lessening of desire with any acute infection of the upper respiratory tract but will have no result on the desire for the pharmacologic effects of the nicotine.

"Moral suasion" or educating the subject regarding the reason for discontinuing the habit, especially with regard to the progress of already existing symptoms, such as extrasystoles

and amblyopia, is usually sufficient. The "withdrawal symptoms" from abstinence from tobacco are so mild when compared with the effects of opiate addiction that similar difficulty need not be anticipated. Many smokers cease to use tobacco for shorter or longer periods out of a whim, to test their self control or for economic, esthetic, hygienic or other reasons. A large proportion of them, however, resume the habit unless they are convinced of its ill effects on their own person.

GYNECOMASTIA

To the Editor:—A man aged 47, 6 feet 1 inch (185 cm.) tall, weighing 173 pounds (78.5 Kg.), complains of a gradual enlargement of the breasts during the last two years. His general health has otherwise been good for many years and his weight has not varied during the last ten years. There is uniform symmetrical development of the two breasts. The nipples are fairly well developed and protrude. There is also a general uniform increase in the fatty tissue of the abdominal wall below the umbilicus and there are fatty cushions over the internal aspect of both knees. There is no urinary dysfunction and no difficulty in performing the sex act though there is a slight decrease in libido. The patient is annoyed only by the increase of the breasts and would like to have the condition corrected. Please suggest a line of investigation and specific treatment. If the latter is not available please suggest a plan of experimental treatment which could be tried. Please give a bibliography.

M.D., Pennsylvania.

ANSWER.—At birth the breasts of a child show hypertrophy as a result of hormone stimulation from the mother during the last three months of pregnancy. For from two to four months after birth, cystic dilatation takes place, after which time the breasts of both sexes are relatively quiescent until puberty.

Estrogenic substance is responsible for growth and branching of the mammary gland trees, possibly slight stimulation of the alveoli and development of the nipples in the female at puberty. In the male the breasts normally remain rudimentary, and within a few years their glandular elements atrophy to almost the degree of practical disappearance.

Geschickter, Lewis and Hartman (Tumors of the Breast Related to the Estrin Hormone, *Am. J. Cancer* **21**:828 [Aug.] *1934*), writing of a condition which they term gynecomastia and which occurs most frequently in white men between the ages of 30 and 40, state: "It may be concluded, therefore, from histological and endocrine studies on the normal male and female breast at birth and at puberty, that the developmental response in mammary tissue at these periods to the female sex hormone, estrin, is homologous to that of gynecomastia."

Some observers believe that mastodynia in women is due to an excess of estrogenic substance, while others think that the condition is due to an insufficient amount of this hormone.

It would seem, since estrone is the stimulator of mammary development in the female, that painful and congested breasts would be due to an excess of hormone rather than to an insufficient amount.

Normal males and females secrete both estrogens and androgens, but under normal conditions of function the excess of hormones are those peculiar to each sex. Gynecomastia has been observed in relation to atrophy and tumors of the testicles, and in some cases to adrenal and pituitary disturbances.

Edwards, Shimkin and Shaver (Hypertrophy of the Breasts Due to Injections of Adrenal Cortex Extract in a Man with Addison's Disease, THE JOURNAL, July 30, 1938, p. 412) reported a case of hypertrophy of the breasts in a man aged 37 with Addison's disease to whom adrenal cortex extract had been administered. The hypertrophy and tenderness of the breasts subsided with omission of the extract and recurred when it was resumed.

In the case mentioned in this query no mention is made of pain, and it will be taken for granted that there is none. In this answer one cannot be definite as to the etiology of the condition in this man. His age, slight description and history suggest a beginning decrease in sex function. It is possible that the enlargement of the breasts is due to an accumulation of adipose tissue. In hypogonad states in both male and female the typical adipose deposits are located in the breasts, the mons and over the trochanters. The fact that the breasts are not painful as a result of the decrease of androgens supports this idea. That an excess of estrogenic substance is present is possible, but hardly probable. Again, adrenal cortex disturbance must be kept in mind. Just how the anterior pituitary could be responsible for the condition would be conjectural.

It might be well to make a series of quantitative determinations for estrogens and androgens. The injection of 25 mg. of testosterone propionate three times a week for one month might be tried but would be in the nature of an experiment. If results were obtained, the injection intervals might be lengthened to once or twice a week.

TYPHUS FEVER

To the Editor:—I should like to make some inquiry as to the course to expect in a case of typhus fever which is under my care. I understand that there is no specific treatment for this disease but would like to know what the convalescence is like and if any after-effects result if recovery occurs. This patient was hospitalized for four weeks and returned home. Everything remained normal, except for extreme prostration, for three weeks and now the whole picture of high fever, severe headaches, delirium and the like is repeating itself. Is this what one can expect and how long may these remissions continue? Is it true that if the patient goes through the first period he usually survives these relapses?

M.D., Pennsylvania.

ANSWER.—It is assumed that typhus fever has not been confused with typhoid.

While there seems to be no reason why a relapse of typhus fever cannot occur, no mention of its occurrence has been found in the literature. Second attacks occurring in the same person after an interval of months or years after the first infection have been observed. Convalescence in uncomplicated typhus fever is usually uneventful, but occasionally patients do have mental or nervous disturbances of a mild degree. Most patients recover and after-effects are uncommon. True relapses in rickettsial diseases seem to be rare.

On reading the query and noting the absence of data, one is apt to wonder on what basis a diagnosis of typhus fever was made. Endemic or murine typhus is uncommon in the winter months, and epidemic or louse-borne typhus is rare in Pennsylvania. The unusual "relapse" mentioned suggests the occurrence of some other disease such as encephalitis.

CONTAMINATED WOUNDS

To the Editor:—What strength of solution of mercury bichloride is advisable to use in irrigating contaminated wounds before suturing? What strength should be used to irrigate the cavity left after the removal of a sebaceous cyst or lipoma in the office as a prophylactic against infection? Is there any danger of mercury poisoning?

M.D., Minnesota.

ANSWER.—The use of mercury bichloride to irrigate contaminated wounds before suturing is not advised in any strength. Fresh wounds should be meticulously cleansed with prolonged washing with soap and water and irrigated with sterile water. Following removal of foreign bodies and devitalized tissue, the wound should then be closed without the use of any antiseptic. There is some, but rather slight, danger of mercury poisoning, but the chief objection to the use of any chemical is that it injures the delicate processes of repair. The use of mercury bichloride to irrigate a cavity left after the removal of a sebaceous cyst or lipoma is not recommended.

VITREOUS OPACITIES FROM HEMORRHAGE

To the Editor:—Are there any means, either operative or medical, other than application of ethylmorphine hydrochloride to the conjunctival sac and internal administration of iodide, for the treatment of vitreous opacities resulting from massive intra-ocular hemorrhages?

H. J. MCGINNIS, M.D., Seymour, Wis.

ANSWER.—There are several measures which have been tried for vitreous opacities such as that described, but the evidence in their favor is not convincing. One is the use of small doses of unfiltered x-rays. A 30 per cent skin dose or 80 roentgens may be used three times at intervals of three weeks without danger to the eye. There is some evidence that the resulting hyperemia tends to hasten the absorption of the opacities. If hemorrhages continue to occur, the use of ascorbic acid (from 1 to 2 grains [0.06 to 0.13 Gm.] a day) is a wise precaution. Removal of part of the vitreous has been carried out and some authors have reported clearing of the vitreous. There is, however, some danger in the procedure, and it is not frequently employed. A recent suggestion is the use of snake venom in small doses, but the results are not established in this type of case.

TWIN PREGNANCY: PROBABLE INTERRUPTION

To the Editor:—A woman aged 42 had her last menstruation Oct. 15, 1938, and there was a scanty and painless flow for two hours on November 12. She has two children and was toxic during both pregnancies but they terminated uneventfully. She was first seen November 21 and a diagnosis of probable pregnancy was made. Pernicious vomiting at once developed which was treated at home but rapidly became worse. She entered the hospital December 16 and was given ordinary treatment (fluids, dextrose, sedatives, corpus luteum). She did not improve, and on December 19, after consultation, a therapeutic abortion was done. The cervix would not admit a finger, and numerous large and small fragments of placenta were removed with ovum forceps. Escape of liquor amnii was not observed. Firm uterine and vaginal packing was inserted and removed in twenty-four hours but no more tissue was passed. She made a quick recovery but persisted in having some morning nausea and vomiting such as would be called normal in pregnancy. Several examinations by myself and my consultant indicate today that there is a progressing pregnancy, normal in every way. Should this pregnancy be allowed to continue when the rather marked degree of placental destruction accomplished at the time of the attempted therapeutic abortion is considered? Since liquor amnii was not evident in the operating room, is it or is it not probable that the fetus is now normal? With the large psychic factor now removed, the patient thinks that she might be reconciled to what was fundamentally an unwanted pregnancy if she could be sure that the child would be normal.

M.D., South Dakota.

ANSWER.—The inquiry indicates that the patient is now between three and three and one-half months pregnant. The history and observations would seem to indicate that she probably had a twin pregnancy with an interruption of one at the time of the operation and a subsequent continuation of the other. This seems to be the most plausible explanation of the clinical course. It is obvious that the fetus and attachments could not have been sufficiently damaged to cause its death, otherwise the pregnancy would not continue and the uterus grow at a normal rate. While the possibility of a hydatidiform mole should be considered, this unusual complication is unlikely in the absence of abnormal symptoms and signs. It is of course impossible to give any woman a positive assurance that the fetus resulting from any pregnancy will be normal and there is no way of diagnosing fetal malformations except certain skeletal deformities. These may be frequently diagnosed late in pregnancy by means of roentgenograms. Even this method lacks positiveness in many instances. It is possible to give the patient every reasonable assurance that with an apparently normal continuation of the pregnancy she has every reason to expect the birth of a normal baby.

GEOGRAPHIC DISTRIBUTION OF PSORIASIS

To the Editor:—Since I am writing an article on psoriasis, I would greatly appreciate it if you would please inform me as to what section of the United States has the most sufferers and why. If you do not have this information, would you please suggest where I could possibly get it.

M.D., Nebraska.

ANSWER.—The section of the United States having the most sufferers from psoriasis is undoubtedly the northern half of the country. The textbooks on dermatology indicate that from 2 to 4 per cent of all cutaneous disorders is psoriasis, but no definite studies of the percentage in various localities has been made. The general impression among dermatologists, however, is that there is less psoriasis in the southern portion of the country. Reports agree that in the tropics there are comparatively few cases of psoriasis. In numerous cases the condition comes under control while the patient is in a warmer climate.

CRYSTALLINE PROTEINS

To the Editor:—Abnormal growths as large as a man's head and apparently due to infection are fairly frequent on semitropical plants. The editorial on the structure of proteins in THE JOURNAL, Dec. 3, 1938, page 2120, leads me to inquire whether the crystalline protein mentioned was derived from a protein of the plant itself or from the protein of the infecting organism; also whether the crystalline protein had the cyclic structure of the plant fossil benzene derivatives and if so whether it is carcinogenic.

G. W. TYRRELL, M.D., Perth Amboy, N. J.

ANSWER.—The experimental evidence available at the present time does not permit a definite answer to the questions put forth. The recent investigation of Martin, Balls and McKinney (*Science* **87**:329 [April 8] 1938) suggests that the virus protein is synthesized at the expense of the normal protein. The investigation referred to is a preliminary communication, and extension and confirmation of this report are certainly required.

No data are available regarding the exact differences in structure between the crystalline virus protein and the proteins of the plant. Bawden and Pirie (*Brit. J. Exper. Path.* **19**:264 [Aug.] 1938) have studied the physical, chemical and serologic characteristics of the protein constituents of normal tobacco and tomato leaves and compared these properties with those of the plant virus proteins. Other than their high molecular weights, the normal plant proteins have little in common with the plant viruses that have as yet been isolated.

Data regarding the possible carcinogenic activity of virus proteins are not available; the inquirer is confusing cyclic structure with benzene nucleus.

TREATMENT OF INFECTED WOUNDS

To the Editor:—I have a patient with an open wound which cultures out Bacillus proteus and Staphylococcus albus. I am using the staphlo jell and have used various mild antiseptics. Do you know of anything specific for Bacillus proteus?

M.D., Wis.

ANSWER.—Extensive experience based on the treatment of many infected wounds in the war and elsewhere has made impressive the value of washing of infected wounds of the soft parts with soap and water. In addition to shaving the surface of the skin for a distance of 4 inches from the edges of the wound and of washing the surrounding skin twice a day with soap and water and gently washing the granulation tissue with soap and water, no other antiseptics are necessary on such wounds, and rapid cleansing of the wound and the appearance of healthy granulation tissue occurs.

HYDROCHLORIC ACID VAPORS

To the Editor:—I am writing to secure information relative to an 18 per cent solution of hydrochloric acid which has been used in industrial work in cleaning lavatories. Other than a bronchitis and an irritation of the nasal passages, can the fumes of such a solution cause gastric and gastrointestinal disturbances?

HARRY LAPIROW, M.D., Cincinnati.

To the Editor:—I am writing you today asking for some information of the effect of muriatic acid on the human system. I have under my care at the present time two patients, both of whom work at the radiator repair industry and who are constantly inhaling the fumes of this muriatic acid that is used in the work. They have symptoms of violent gastrointestinal disturbance, headache and backache with tenderness over the entire abdomen. We are having a mild epidemic of typhoid in our city, but I am unable to get either a positive blood or a positive stool culture on these patients. I will appreciate it, therefore, if you will send me any information available on this matter.

C. H. STARK, M.D., Cedar Rapids, Iowa.

ANSWER.—The constant exposure to vapors of hydrochloric acid will cause irritation of exposed mucous membranes. Thus the vapors will produce conjunctivitis, rhinitis and bronchitis. Hydrochloric acid has also a definite effect on dentition, producing inflammation of the gums and a loosening of the teeth. It is said that definite gastrointestinal irritation also results from the inhalation of these vapors with the production of nausea, vomiting and epigastric distress. Statistics and data on this subject, however, are limited, although there is more information on the effects of chlorine gas.

OPTOMETRISTS RECEIVE MISINFORMATION

To the Editor:—In the January 15 issue of the *Optical Journal and Review of Optometry*, page 20, I find the following statements on intraocular pressure. "The third nerve is a part of the somatic which innervates the muscles of more recent origin, and their function is all in a positive direction or to increase the hydro pressure. The sympathetic is the autonomous which innervates the muscles whose origin is in the very early stages of development, and their function is to keep the pressure down in coordination with the vegetative system." Can you elucidate these statements? They do not seem to agree with my conceptions of the physiology of the eye.

FREDERICK A. WIES, M.D., New Haven, Conn.

ANSWER.—Only too frequently appear questions that are inaugurated by hopelessly inaccurate statements appearing in journals that have no scientific supervision. Unfortunately the majority of the human race tends to believe what it sees in print as gospel truth without inquiring into the authenticity of the statements. Libel laws protect human beings but unfortunately medical topics have no such legal champions. Practically all of the fifty-seven varieties of the pseudomedical cults have publications of one sort or another. In these the various authors justify their extravagant claims by misquotations from authoritative sources or by statements snatched from the blue sky. To the uninitiated such articles are convincing, but no physician should allow himself to be taken in by these pseudoscientific libels.

DISLOCATION OF HEAD OF RADIUS

To the Editor:—Yesterday at a clinic I saw a patient with an anterior dislocation of the head of the radius of five years' duration. The patient complains of occasional attacks of pain accompanied by "purplish" discoloration in the region. Are there any operative procedures which might give a good result in a case such as this? Please quote references if possible. I haven't been able to find anything satisfactory in books to which I have access.

LUCIAN J. FRONDUTI, M.D., Jessup, Pa.

ANSWER.—The head of the radius is in close proximity to the posterior interosseous nerve. It is possible to resect the head of the radius not only without functional disability but in many cases with a considerable increase in function.

The purplish discoloration complained of may have nothing to do with the dislocation of the head of the radius but may be due to some local circulatory disturbance, possibly of venous or sympathetic nerve origin.

In considering a dislocation of the head of the radius, one must presuppose a rupture of its surrounding orbicular ligaments. There is a well known fracture-dislocation, known as a Monteggia dislocation, which is a fracture of the shaft of the ulna in connection with dislocation of the head of the radius.

SUPERFECUNDATION, SUPERFETATION AND INTERVAL BETWEEN TWIN BIRTHS

To the Editor:—1. What is now considered to be the possibility of superfecundation and what is the latest time at which it can occur? 2. What is the supposed mechanism of the birth of twins days or weeks apart?

M.D., Illinois.

ANSWER.—1. Superfecundation is the impregnation of two different ova about the same time by sperms of different fathers. A white woman may bear twins, a black and a white child; a Negress may bear a black and a mulatto twin, but both combinations are possible with a single father. To prove superfecundation it is necessary that the twins be of a race different from the mother; e. g., a white woman delivers a Negro and a Mongolian.

The two impregnations must occur within a day or two to fertilize the two ova of one ovulation. Superfecundation occurs in multiparous animals.

Superfetation means the fertilizing of ova of two ovulations; i. e., a pregnancy supervening after one already occupies the uterus. This possibility has been strenuously denied by many authorities. The occasional great disparity in the size of the two children—reported as much as 1 to 7—has been ascribed to unequal development resulting from difference in nutrition. But superfetation does occur in human beings; e. g., a case of a healthy ovum of 4 weeks being found with a healthy aborted fetus of 10 weeks; also laboratory and clinical proof quoted by DeLee (ed. 7, p. 538). Superfetation occurs in multiparous animals not infrequently, and in the mare and cow on rare occasions. A mare served by a donkey and, a month later, by a stallion gave birth 9 months later to a mule and one month thereafter to a filly (Fleming: Veterinary Obstetrics, p. 127).

2. The mechanism of the causes of the delay in the delivery of the second twin days or weeks after the birth of the first is not understood, and a satisfactory explanation is not to be anticipated until what normally sets the process of labor in motion is known. Superfetation would be a dubious solution in the human race.

PERIODIC ALCOHOLIC EXCESSES

To the Editor:—I have been asked for advice in a case of dipsomania. A man aged 55, with a good physique, height about 70 inches (178 cm.) and weight 180 pounds (81.6 Kg.), is active and shows no signs of chronic alcoholism. His tongue is clean and there are no tremors or facial characteristics common to this condition. The family history is negative except that the father drank moderately. He has no brothers or sisters. He married a young woman in 1930 and has two normal, healthy boys aged 4 and 7. The wife does not drink or smoke, and since they seem to be happy in their married life there seems to be no exciting cause here. The patient had typhoid in 1911 and two or three attacks of influenza in 1915 and 1918. He has never been operated on. There is no history of delirium tremens or of institutional treatment. The heart is normal, the urine is normal and the blood pressure is 110 systolic, 60 diastolic; in fact all functions appear to be normal. He was with one employer for twenty years and is now retired on a moderate income. As near as I can find out, he leads a normal life and has traveled extensively. He says that he has used alcohol since his college days, but moderately. Usually he drinks beer and does not care for strong drink except when he is on a spree. He goes months—around 1933 he had no alcohol of any kind for eighteen months—at other times drinks two or three glasses of beer a day for months without going on a spree. He has attended social functions and taken two or three cocktails and thought nothing more of it. I cannot seem to find out how he happens to get started. After a few days of drinking, from four to seven, he suddenly stops of his own accord. He remains in bed two or three days and then gets back into good condition in a short time. The attacks have no regularity—may be two or three in as many months and then a year or more between attacks. I am in hopes that there may be some routine, with or without drugs, that he could follow to lessen if not entirely do away with this disease. Any information will be most acceptable.

W. G. STEADMAN, M.D., Miami, Fla.

ANSWER.—The periodic sprees are probably due to psychic causes in spite of the negative history. It is likely that a careful inquiry would elicit a history of troubles from which he is trying to escape. It is possible that the attacks could be prevented if the patient would consult his physician when he feels that a spree is imminent. Possibly at this time a little sympathetic psychotherapy with or without the use of sedatives such as bromides, phenobarbital or paraldehyde might be helpful.

TOXICITY OF OCTYL ALCOHOL

To the Editor:—Will you kindly inform me as to the toxicity of vapors from normal octyl alcohol (capryl alcohol). The vapors escape from a condenser during distillation.

R. J. FOSTER, M.D., New Philadelphia, Ohio.

ANSWER.—Octyl alcohol ($C_8H_{17}OH$) lately has come into extensive use as an antifoaming agent. It is used on such a large scale as to be marketed in carload lots. Among other processes, it is used in connection with dehydrating lubricating oil, the printing of textiles, water sprays used for air conditioning, the manufacture of paper, photographic work, insecticide sprays and the like. While little is known about its toxic properties, its extensive use with apparent impunity prompts the belief that its toxicity for exposed workmen is of low order. This substance possesses a fairly disagreeable odor, which in some instances may be a deterrent to its use.

A number of studies have been made on the action of octyl alcohol on experimental animals: Octyl alcohol dissolved in ethyl alcohol provokes a drop in arterial pressure, and after repeated injections death may occur. Intravenous injections of octyl alcohol promote diuresis. A mild local anesthetic property is possessed by this alcohol. Clotting time is increased as a result of the action of octyl alcohol when injected intravenously. Additional data related to pharmacologic action may be found in the following references:

RECURRENCE OF LYMPHOID TISSUE AFTER TONSILLECTOMY

To the Editor:—What is the incidence of return of some varying amount of tonsil tissue after tonsillectomies done in children 3 years of age and how soon afterward may some such tissue appear?

M.D., New Jersey.

ANSWER.—There are no reliable statistics on the incidence of return of tonsil tissue in the pharynx of children tonsillectomized at the age of 3 years. Recurrence is dependent on a number of factors, not all well understood. Among these factors is age. There is a normal tendency toward hyperplasia of all the lymphatic structures in Waldeyer's ring in the first few years of life. Removing the tonsils at an early age leads often to compensatory hypertrophy of the surrounding lymphatic structures as well as to recurrence in the operative site. Hence, the younger the person at the time of operation the more apt is recurrence to take place. Furthermore, some persons show a special tendency toward hyperplasia. These will tend to suffer from recurrences.

Early reappearance of lymphoid tissue on the tonsillar fossa speaks for an incomplete operation. Late recurrence, sometimes several years after a technically well performed removal, is possibly due to the lymphatic structures present in the tunica propria of the mucosa, which grows in to heal the site of operation.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, May 27, page 2197.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: Parts I and II. Medical centers having five or more candidates desiring to take the examination, June 19-21 and Sept. 11-13. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th Street, Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF ANESTHESIOLOGY: An Affiliate of the American Board of Surgery. *Written.* Various places throughout the United States, Sept. 9. Applications must be filed by July 11. *Oral.* Part II. Philadelphia, Oct. 14-15. Sec., Dr. Paul M. Wood, 745 Fifth Ave., New York.

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: Philadelphia, Oct. 30-Nov. 1. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written.* Various sections of the United States, Oct. 16 and Feb. 19. Formal application must be received before Aug. 20 for the Oct. examination and on or before Jan. 1 for the Feb. examination. Sec., Dr. William S. Middleton, 1301 University Ave., Madison, Wis.

AMERICAN BOARD OF OPHTHALMOLOGY: *Written.* Various cities of the United States, Puerto Rico and Canada and in Honolulu, Aug. 5. *Application must be received before July 1. General Oral.* Chicago, Oct. 7. Sec., Dr. John Green, 6830 Waterman Ave., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: *Boston, January.* Sec. Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: Chicago, Oct. 6-7. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PEDIATRICS: Cincinnati, Nov. 15. Appointments must be made before July 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

California February Examination

Dr. Charles B. Pinkham, secretary, California State Board of Medical Examiners, reports the written examination held at Los Angeles, Feb. 7-9, 1939. The examination covered nine subjects and included ninety questions. An average of 75 per cent was required to pass. Fifty-seven candidates were examined, fifty-three of whom passed and four failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
College of Medical Evangelists		(1937)	78.6, 79.4, (1938) 75.8, 78, 82.7

Book Notices

Clinical Electrosurgery. By Gustavus M. Blech, G.C.S., G.C.G., M.D., Consulting Surgeon Westlake Hospital, Chicago, Illinois. With chapters by Hector Alfred Colwell, M.B., Ph.D., D.P.H., Senior Assistant in Cancer Research Department Middlesex Hospital, London, and Brian Wellington Windeyer, F.R.C.S., D.M.R.E., Radium Officer Middlesex Hospital, London, England. Cloth. Price, $4. Pp. 389, with 34 illustrations. New York, Toronto & London: Oxford University Press, 1938.

Electrosurgical methods have come to fill a role in both major and minor operations. The ballyhoo of apparatus salesmen of a decade ago, promising every general practitioner that he could by the turn of a knob of a diathermy machine operate on tonsils and hemorrhoids, has been largely replaced by a realization that specially constructed electrosurgical apparatus must be painstakingly used by competent surgeons and other specialists. However, there has been a decided dearth of an authoritative textbook on the subject. The present volume fills this need. Part I is devoted to general considerations. The chapter on the historical development of electrosurgery is by H. A. Colwell. Other chapters deal with electrosurgical procedures, equipment, general technic, indications and limitations and nomenclature. A final chapter, on the radiotherapy of neoplasms, is by Windeyer and Colwell. In his own chapters the author has avoided going into complicated physics or a description of apparatus and presents the technical aspects of the general technic and the clinical applications lucidly and critically. The details on anesthesia and operative procedures and the advice for the gradual acquisition of a proper technic are comprehensive. The author puts strong emphasis on the use of electrosurgical measures in the treatment of malignant neoplasms and advocates biopsy by electrotomy as the only safe procedure. Part II comprises the major part of the volume and deals in successive chapters with operations on the skin, the head and spine, the face and neck, the thorax, the abdomen, the genitourinary apparatus, the female pelvis, the extremities, the nose, throat and larynx and the eye. The author limits his recommendations to methods and indications which he considers thoroughly tried.

Die fetale und postfetale Tuba Eustachii: Anatomisch-histologische Untersuchungen. Von Adolf Schwarzbart. Extrait des Mémoires de l'Académie polonaise des sciences et des lettres, Classe de médecine, 1938. Paper. Pp. 160, with 80 illustrations. Cracow: Imprimerie de l'Université, 1938.

Here is a richly illustrated work devoted chiefly to a study, anatomic and microscopic, of the eustachian tube. The author has covered his ground with a thoroughness reminiscent of the prewar Teutonic school. He gives the history of previous investigations and a summary of present knowledge of the eustachian tube. A discussion of points of embryologic interest, a survey of comparative anatomic details and a review of current notions relative to the physiology of the eustachian tube are presented. The author's material was human and animal, chiefly human and obtained from several dozen fetuses ranging in age from 5 to 10 months and from about sixty-five infants, children and adults. With great detail he discusses the anatomy and histology of the eustachian tube in the light of his observations, leaving, it would appear, little else to be done. For the anatomist and perhaps the otologist deeply interested in the subject, this work offers in one volume an immense amount of detail not to be had, as far as can be determined, anywhere else.

The Pituitary Gland: An Investigation of the Most Recent Advances. The Proceedings of the Association for Research in Nervous and Mental Disease, New York, December 28th and 29th, 1936. Editorial Board: Walter Timme, Angus M. Frantz and Clarence C. Hare. Association for Research in Nervous and Mental Disease, Vol. XVII of a Series of Research Publications. Cloth. Price, $10. Pp. 764, with 160 illustrations. Baltimore: Williams & Wilkins Company, 1938.

The Association for Research in Nervous and Mental Disease in previous years has had similar symposiums on various topics of interest in its field. This volume represents three symposiums concerning the anatomy and the physiology of the pituitary gland and a series of articles of interest largely from the clinical point of view. It is profusely illustrated, and the material is the most recently collected on this subject. Of particular interest was the suggestion by Dr. Timme that the regions with a preponderance of cases of the pituitary syndrome are almost identical with the areas commonly called the "goiter belt." Notwithstanding the vast amount of material here assembled, it becomes promptly apparent to the reader that exact knowledge concerning the gland and its functions is still in the early stages of development. The evidence is clear that the pituitary must be considered as part of the glandular chain and that much knowledge must await suitable integration of information concerning each of the portions of this interlocking directorate of the human body.

Handbuch der Inneren Medizin. Begründet von L. Mohr und R. Staehelin. Herausgegeben von G. v. Bergmann und R. Staehelin unter Mitwirkung von V. Salle. Band III: Krankheiten der Verdauungsorgane. Teil 1: Mundhöhle, Speiseröhre, Magen. Teil 2: Darm, Bauchfell, Bauchspeicheldrüse, Leber und Gallenwege. Bearbeitet von W. Baumann, et al. Third edition. Paper. Price, 108 marks. Pp. 789; 791-1514, with 504 illustrations. Berlin: Julius Springer, 1938.

This volume is devoted to a consideration of the disorders and diseases of the entire digestive tract, including the liver and biliary passages, pancreas and diaphragm. The extensive clinical and pathologic consideration is preceded by a brief but concise summary of the anatomic and physiologic aspects. As is characteristic of Teutonic writings, the references to the literature are almost exclusively German, but many of the most important contributions of English, American and French investigators are mentioned. Diseases of the mouth and esophagus are well portrayed by Gigon and Lüdin. The chapter on diseases of the stomach was written by Katsch and Kalk, two distinguished specialists in the field of gastro-enterology. Von Bergmann contributed an article on the pathogenesis of ulcer in which he ascribes much importance to the spasmogenic or neurogenic theory with which his name is closely identified.

Gastritis is exhaustively covered by Katsch, his description reflecting the importance with which this entity is regarded in central Europe. Until recently the subject has not been given deserved consideration in this country. The colored plates on pages 452 and 453, depicting the gastroscopic appearance of the acute and chronic forms of gastritis, are some of the finest extant. In fact, nearly all the illustrations, particularly the reproductions of roentgenograms, are excellent. Diagnostic laboratory procedure with reference to the various organs is discussed in considerable detail. In the treatment of ulcer Kalk looks with disfavor on antacids and advocates the use of bismuth compounds and atropine. In cases in which the ulcer is refractory he still makes use of nonspecific forms of protein therapy. He greatly favors gastric resection in the surgical treatment of all ulcers not responding favorably to medical management, and in his experience about half of the patients submitted to gastrojejunostomy had recurrences. In the treatment of gastric hemorrhage he takes a conservative point of view, especially when the patient is less than 50 years old.

The chapter on diseases of the liver and biliary passages was contributed by two authors less well known to the English speaking members of the profession, Dr. Stroebe and Dr. Schweigk, both of Berlin. It is, however, one of the most complete in the volume. The observations on the physiology and functional pathology of the organ by the junior author and the articles on special pathology by Stroebe are interesting and instructive. Naturally the theory of serous inflammation conceived by Roessle and Eppinger is given much consideration. Henning and Baumann contribute the chapters on diseases of the intestine and diaphragm. Entities such as regional ileitis, syphilis and ulcerative gastritis are treated rather briefly, considering their growing importance.

The new edition of the handbook easily measures up to the high standards set by preceding editions. The editorship in itself would be a guaranty of such excellence. To those familiar with the language and with special interest in this field of medicine it is heartily recommended.

The Medical Press and Circular 1839-1939: A Hundred Years in the Life of a Medical Journal. By Robert J. Rowlette, M.D., F.R.C.P.I. Cloth. Pp. 127, with 10 plates. London, 1939.

This book was published in celebration of the hundredth anniversary of the *Medical Press and Circular*, which was founded in Dublin in January 1839 under the title of the *Dublin Medical Press*. The author was for many years Irish editor. The *Medical Press* in 1866 absorbed the *Medical Circular*, a London periodical founded in 1852. During its Dublin days this journal took an active interest in bettering the position of the members of the medical profession in government employ and in the development of the organization of the profession. In both earlier and later years it maintained a constant warfare against quackery and unprofessional conduct, particularly of those in high places. Such warfare brought the journal into difficulty at times, but only once was it taken into the courts and on that occasion the costs were defrayed by public subscription. So-called medical politics played a part in the editorial policy, but that was far from being the major interest. In its early volumes, among other things were the proceedings of the Royal Society of London, of the Royal Irish Academy, of the Academy of Sciences of Berlin and of the Zoological Society of London. As time went on the scope of the journal was narrowed to medicine, and in recent years the *Medical Press and Circular* has pursued the policy of providing concise articles on the latest accepted methods of diagnosis and treatment. The details of the long life of this journal are interestingly related by the author. In appearance the book, printed on double edged cream antique laid paper, is artistic. There are ten plates, some of which are portraits of the earlier editors.

Social Work Year Book 1939: A Description of Organized Activities in Social Work and in Related Fields. Russell H. Kurtz, editor. Fifth issue. Cloth. Price, $3.50. Pp. 730. New York: Russell Sage Foundation, 1939.

This constitutes the fifth issue of a description of organized activities in social work and related fields. A considerable number of contributors are responsible for the material included. Unfortunately the work bears too largely the stamp of the field of social service and there is little to indicate any point of view except that point of view. For instance, medical care is covered by Michael M. Davis and health insurance by I. S. Falk. In reference to surveys of medical needs there is not the slightest mention of the American Medical Association except to point out that it opposed some of the conclusions of the Committee on the Costs of Medical Care. In the discussion of new plans for medical care the organized medical profession is put in the position of opposing everything; the reader is in fact given a

completely biased picture of the entire situation. If the publisher had been concerned with presenting to the readers an actual picture of the status of the various fields which are discussed, he might at least have indicated the existence of the diverse points of view. The book is, however, useful as a guide to the extent of activities in the field of social work.

Praktische Anatomie: Ein Lehr- und Hilfsbuch der anatomischen Grundlagen ärztlichen Handelns. Von T. von Lanz und W. Wachsmuth. Band I, Teil 4: Bein und Statik. Cloth. Price, 49 marks. Pp. 485, with 342 illustrations. Berlin: Julius Springer, 1938.

Von Lanz was a professor of anatomy at the University of Munich; Wachsmuth was dozent in surgery at the University of Bonn. This book deals with the lower extremity; one on the upper extremity was published three years ago; parts dealing with the rest of the body are in preparation. The authors and the publisher have produced an extraordinarily beautiful, scholarly and well illustrated work. The title "Praktische," or applied, anatomy suggests that surgical and clinical anatomy will be presented. That expectation is abundantly fulfilled both in the text and in the numerous and excellent illustrations. The results of injury, the relation of muscular action to fractures, the desirable sites of amputation and of ligation of vessels, the collateral circulation, the best surgical approaches, the results of disease of the peripheral nerves all are well treated. But the book presents much more than this. It is one of the most beautiful books in the literature on descriptive, topographic, functional and developmental anatomy. The physical anthropology of the lower extremity, the action of muscles, the mechanics of joints, the range of motion and normal variations in this range and the mechanics of the circulation of blood in arteries, veins and capillaries are presented in text and illustrations with thoroughness and clearness. The illustrations are new and of unusual beauty. The general nature of the book may be inferred from their character. Two thirds are devoted to normal anatomy, twenty-two to growth and development, six to physical anthropology, thirty to function and over forty to purely clinical subjects. Thirty-two pages is devoted to a thorough and well classified reference to the literature and forty to an excellent and serviceable index. The appearance of further parts will be eagerly awaited by anatomists, physicians, surgeons, physical anthropologists and students.

Gould's Pocket Pronouncing Medical Dictionary of the Principal Words Used in Medicine and the Collateral Sciences with an Appendix Containing Complete Tables of the Arteries, Bones, Chemical Elements, Hormones, Micro-Organisms, Muscles, Nerves, Prefixes and Suffixes, Phobia's Signs and Symbols, etc., Also a Physicians Dose-List of Drugs with Their Incompatibilities, and a Veterinary Dose Table Both in the English and Metric Measures, and Based Upon the Eleventh Revision U. S. Pharmacopœia. By the Late George M. Gould, A.M., M.D. Revised by C. V. Brownlow. Eleventh edition. Fabrikoid. Price, $2; Thumb Index $2.50. No pagination. Philadelphia: P. Blakiston's Son & Co., Inc., 1939.

The eleventh edition of this well known dictionary contains more than 40,000 words of medical import. It includes a number of tables on hormones, bacteria, signs, symbols and abbreviations, and doses. Many of these are placed in the back of the book as an appendix. This is a useful volume and can be carried in a large pocket or in a physician's bag.

Cancer: An Inquiry into the Extent to Which Patients Receive Treatment. By the Hon. Sholto Mackenzie, M.D., M.R.C.P. Ministry of Health, Reports on Public Health and Medical Subjects, No. 89. Paper. Price, 9d. Pp. 41. London: His Majesty's Stationery Office, 1939.

The objective of the inquiry was "to obtain information as to the number of persons with cancer who received treatment and the circumstances under which treatment was, or was not, received. For this purpose data derived from the histories of those who had died of cancer have been utilised." The histories of 3,303 patients, which it was felt could "fairly be considered as a reasonably representative sample," were thus studied. Of these 2,420, or 73 per cent, did not obtain treatment. There were 418, or 12 per cent, who first sought advice within four weeks of death; 237, or 7 per cent, refused treatment; 169, 5 per cent, suffered from concomitant disease which rendered treatment difficult or impossible; 426, or 13 per cent, were too old for treatment, and 657, or 20 per cent, were cases in which the condition was too advanced for treatment. The cases were then analyzed to determine whether the location of the cancer was such as to have given a reasonable probability that treatment might have been helpful. Forty-two per cent of 312 who refused treatment gave as their reasons dislike of the hospital, treatment considered useless or fear or they preferred to remain at home. A similar study (Lombard, H. L.: Education a Major Need in Adequate Medical Care, THE JOURNAL, Nov. 5, 1938, p. 1747) conducted by the Massachusetts Department of Public Health found that 37.4 per cent of the "persons dying of cancer without reporting for treatment" after cancer had been diagnosed gave similar reasons. There may be some significance in the fact that not once in the entire report is any reference made to health insurance as a means of detecting incipient cancer.

Consolidated Indices Embracing Transactions of the American Roentgen Ray Society (1903-1908), American Quarterly of Roentgenology, Volumes I-V (1906-1913), American Journal of Roentgenology, Volumes I-IX (1913-1922), American Journal of Roentgneology and Radium Therapy, Volumes X-XXXVIII (1923-1937). Author and Subject: 1903-1937. Compiled under the direction of the Publication Committee and the Editorial Office of the American Roentgen Ray Society. Cloth. Price, $12.50. Pp. 451. Springfield, Illinois: Charles C. Thomas, 1939.

The publisher has here made available a complete index in the field of roentgenology, embracing the transactions of the American Roentgen Ray Society from 1903 to 1908 and material from three of the leading journals in the field of roentgenology for long terms of years. The index covers not only the transactions of the society and the original articles, editorials and biographic and historical sketches that have been published but also the abstracts from both domestic and foreign journals. As this material concerns the beginnings of our knowledge of roentgenology, the index constitutes an invaluable guide to material of permanent historical importance.

Mundherde und Gelenkrheumatismus: Ein Beitrag zur Bakteriologie der oralen Herdinfektion. Von Hofrat Dr. Franz Schick. Paper. Price, 7.50 marks. Pp. 86, with 11 illustrations. Leipzig: Johann Ambrosius Barth, 1938.

The author believes that the teeth are the only controllable foci. Oral infection is only one of numerous foci, but it is important since the mouth is the great portal of entry to the gastrointestinal tract and is in intimate relationship to the upper respiratory tract, paranasal sinuses, mucosa, teeth, salivary ducts, tonsils and polypous growths. Schick thinks that the American allocation of the teeth as the focus in 10 per cent of cases is too conservative. The tonsils are second in importance. The author describes a gram-labile micrococcus which he and Fischer isolated. This organism was found in the blood stream of five of seven rheumatic patients; it was present in tonsils, granulomas and the pulp of dead teeth. Its pathogenicity is low. Other subjects considered are the blood picture, which is not characteristic, focal infections, polyarthritis rheumatica from the standpoint of pathologic anatomy and experimental work on Micrococcus Fischer-Schick. A large bibliography is appended

Traité de thérapeutique clinique. Par Paul Savy, professeur de clinique médicale à l'Université de Lyon. Tomes I, II, et III. Second edition. Cloth. Price, 450 francs per set. Pp. 958; 959-2075; 2077-2776. Paris: Masson & Cie, 1938.

The fact that a second edition appears within two years of the first edition is evidence of the popularity of this treatise. A department representing the dermatologic and urinary specialties has been added, and the book has been brought down to date; otherwise the arrangement of the work is the same as in the previous edition. The practicability of the work is evident throughout, as is shown among other things by the introduction of illustrative prescriptions useful in the treatment of various diseases. The first volume deals with the treatment of pain, syphilis, tuberculosis, cancer, gastrointestinal disturbances and diseases of the liver and pancreas and concludes with the diseases of blood and blood-making organs. The second volume includes diseases of the heart and blood vessels, kidneys, respiratory apparatus and nervous system. The third volume includes the treatment of disturbances of the endocrine glands, allergy, dyscrasias, infectious diseases and intoxications. The work can be recommended for its exposition of the generally accepted practice of medical treatment in France.

Whitla's Dictionary of Treatment Including Medical and Surgical Therapeutics. By R. S. Allison, M.D., M.R.C.P., Physician with Charge of Out-Patients, Royal Victoria Hospital, Belfast, and C. A. Calvert, M.B., B.Ch., F.R.C.S.I., Assistant Surgeon, Royal Victoria Hospital, Belfast. Eighth edition. Cloth. Price, $9. Pp. 1,285. Baltimore: William Wood & Company, 1939.

Sir William Whitla, a prominent physician of Belfast, Ireland, wrote this book and edited it through seven editions. He died in 1933 and so many advances have been made since that it was necessary for new editors to rewrite it. Sir William's original plan of dealing with each subject from the general practitioner's point of view has been followed. In addition to the editors there are ten special contributors, all members of the Belfast school. As the title indicates, they follow the dictionary plan, but there is an index in the back. The book is probably as nearly abreast of the times as a book of its scope could be. However, under pellagra there is no mention of the use of nicotinic acid, although there is brief mention of the treatment by means of yeast and vitamin B.

Organic Chemistry. By Paul Karrer, Professor in the University of Zürich. Translated from the latest German edition by A. J. Mee, M.A., B.Sc., Head of the Science Department, Glasgow Academy, Glasgow. Cloth. Price, $11. Pp. 902. New York: Nordemann Publishing Company, Inc.; Amsterdam: "Elsevier," 1938.

This volume presents the subject in a concise manner, covering practical information of a broad scope and making readily available a commanding and recent survey by a noted chemist. It is based on the fifth German edition; corrections and additions of the sixth edition have been included. The changes in the recent editions not being great, the new advances are allotted space. Discussions of vitamins B_1 and E, the cortical steroids and organic compounds containing heavy hydrogen are included. Advanced students will find the text a reliable source of information. It supplies a sound groundwork, along with enough background for the consideration of various theories and topics. The book can be heartily recommended for every chemist's library.

Doctors, Nurses and Dickens. By Robert D. Neely. Cloth. Price, $1.50. Pp. 153, with 3 illustrations. Boston: Christopher Publishing House, 1939.

Here a Dickens enthusiast has assembled everything that the great master wrote concerning doctors, nurses and the medical profession. The volume is of interest and contains a vast amount of most quotable material.

Landmarks in Medicine: Laity Lectures of the New York Academy of Medicine. Introduction by James Alexander Miller, M.D., President, New York Academy of Medicine. Cloth. Price, $2. Pp. 347, with 15 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1939.

The New York Academy of Medicine has been conducting for some years a series of lectures for the public in the field of medical science. The present volume includes some excellent essays, mostly historical. The following items are included, in addition to the introduction by Dr. James Alexander Miller:

From Barber-Surgeons to Surgeons, by Francis R. Packard, M.D.
The Meaning of Medical Research, by Alfred E. Cohn, M.D.
Dr. Watson and Mr. Sherlock Holmes, by James J. Walsh, M.D.
The Search for Longevity, by Raymond Pearl, Ph.D.
Medicine and the Progress of Civilization, by Reginald Burbank.
X-Ray Within the Memory of Man, by Lewis Gregory Cole, M.D.

From the point of view of scientific information, the one most useful is the essay of Dr. Raymond Pearl.

Pechenochno-pochechnyi sindrom v chirurgii (hepato-nephrity): Eksperimentalnoklinicheskoye issledovanie. [By] Prof. A. Ya. Pytel. [Hepatorenal Syndrome in Surgery (Hepato-Nephritides): Experimental-Clinical Investigation.] Cloth. Pp. 157, with 11 illustrations. Stalingrad: Oblastnoe Knigoizdatelstvo, 1938.

Professor Pytel reports his clinical and experimental investigations dealing with the failure of the hepatic and the renal function in surgical diseases and in particular after operations on the liver and the biliary tract. The author was able to reproduce experimentally intraperitoneal autolysis of the liver tissue in dogs. Morphologic alterations in the liver and in the kidney were found to be analogous to those present in persons dying from liver disorders. The author concludes that loss of renal function in the so-called renal syndrome is due to damage to the glomeruli and the urinary canaliculi by toxic substances originating in the damaged liver or brought from the intestine to the liver which had lost its detoxifying function. The monograph presents an exhaustive discussion of the causes, the clinical manifestations and the prophylactic and active treatment of the hepatorenal syndrome. The monograph is written in Russian with a brief summary in French.

Sbornik trudov posvyashchenny XL-letiyu nauchnoy i uchebnoy deyatelnosti zasluzhennogo deyatelya nauki professora V. N. Shevkunenko. [Collection of Works Celebrating 40 Years of Scientific and Pedagogic Activity of V. N. Shevkunenko.] Cloth. Price, 12 rubles, 50 kopecks. Pp 306, with illustrations. Leningrad: Izdanie Voenno-Meditsinskoy Akademii RKKA im S. M. Kirova, 1937.

These two volumes constitute a festschrift dedicated by the faculty of the Military Academy of Leningrad to one of its most gifted sons, V. N. Shevkunenko, professor of operative surgery and topographic anatomy, on the occasion of his completion of forty years of clinical, pedagogic and experimental activity within the walls of the academy. Volume 1 contains papers dealing with studies on constitutional types, a subject to which Shevkunenko devoted much of his attention. Volume 2 contains papers dealing with various subjects in the field of operative surgery. The text reflects the standard of Soviet surgery and suggests that the traditions of the academy which not long ago could boast of such names as Sechenov, Pavlov, Pirogov and Fedorov are being perpetuated.

The Proceedings of the Charaka Club, Volume IX. Post Multa Virtus Opere Laxare Solet. Published for the Charaka Club. Boards. Price, $5. Pp. 204, with illustrations. New York: Richard R. Smith, 1938.

The ninth volume of the Proceedings of the Charaka Club contains some exceedingly interesting essays, poems and experiments in literature by the members of this erudite organization. The book has interest not only for the medical historian but for all persons who are interested in the literary and artistic portrayal of the medical scene. Especially fascinating is the opening essay by Dr. Harvey Cushing, which deals with Ercole Lelli. The book is beautifully printed in the same style as the previous volumes. The complete collection of the Proceedings of the Charaka Club is now a most valuable contribution to medical history.

Seventeenth Hospital Yearbook. 1939 Hospital Purchasing File: Directory of Products, Manufacturers' Catalogs, Purchasing Standards and Other Reference Data. Boards. Price, $2.50. Pp. 801. Chicago, Illinois: Modern Hospital Publishing Company, Inc., 1939.

The seventeenth edition of this yearbook, like its predecessors, is a compendium of information for purchasers. Practically everything used in building and operating a hospital is included. The material is helpfully indexed and classified. The last fifty pages present special articles on various classes of hospital apparatus, from air humidifiers to devices for refrigeration and insulation. There is a comprehensive check list for the purchase of hospital equipment and a list of national, state and sectional hospital and allied agencies.

Shok (Pratsi konferenstii z problemi shoku) Kiïv, 25-27 grudnya 1937 roku. [Shock. Transactions of Conference on Problems of Shock. Kiev, Dec. 25-27, 1937.] Paper. Price, 15 krb. Pp. 354, with illustrations. Kiev: Vidavnitstvo Akademii Nauk URSR, 1938.

This volume contains a number of papers dealing with the various aspects of clinical and experimental shock. Each contribution is accompanied by a summary in English or in French. There is a bibliographic supplement embracing most of the important literature on the subject written between 1931 and 1937. The experimental work is frequently of a high standard and as such should prove of interest to physiologists and clinicians.

Sbornik trudov posvyashchenny XXXV-letnemu yubileyu vrachebnoy, nauchnopedagogicheskoy i obshchestvennoy deyatelnosti zasluzhennogo deyatelya nauki Professora I. I. Faynshmidta. Redaktsionnoe byuro: V. P. Vorobev i A. I. Levin (otvetstvennye redaktory). Recueil de travaux consacré au XXXV anniversaire de l'activité médicale, scientifique, pédagogique et sociale du travailleur émérite de la science professeur I. I. Fainschmidt. Paper. Price, 14 rubles. Pp. 466, with illustrations. Kiev: Gosmedizdat USSR, 1937.

This is a festschrift issued by the Ukrainian Institute of Experimental Medicine and dedicated to I. I. Fainshmidt on the occasion of his completion of thirty-five years of clinical, peda-

gogic and communal activities. The papers deal with various clinical aspects of pneumonia, tuberculosis, cardiovascular disease and diabetes. Professor Fainshmidt, one of the most prominent internists of the Ukraine, has contributed much to these subjects. Each paper is accompanied by a brief summary in French.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Dead Bodies: Removal of Gold Crowns from Teeth as Mutilation of Body.—The defendant, an embalmer, was convicted of feloniously mutilating a dead body and appealed to the district court of appeal, second district, division 2, California.

Section 290 of the Penal Code of California provides that every person who "mutilates" a dead body of a human being without authority of law shall be guilty of a felony. It was for an alleged violation of this section that the defendant was arrested and subsequently convicted. The evidence was construed by the appellate court to show that the defendant removed two gold crowns from the teeth of a dead body. The trial court instructed the jury that the word "mutilate" as used in the Penal Code meant to destroy or remove a material part of so as to render imperfect. But, said the appellate court, in none of the dictionaries, either legal or general in scope, can there be found a definition of the word "mutilate" as applied to the human body which is couched in the language used by the trial court or in any similar language. Legal dictionaries, on the contrary, are in accord that the term "mutilate" means to cut off a limb or an essential part of the body or "to deprive a man of the use of those limbs which may be useful to him in fight." Without the use of dictionaries, the court pointed out, it would be difficult to conclude that one who removes gold crowns from the teeth of a dead body could be properly accused of mutilating the body. The evidence in the present case showed that the natural teeth of the dead body were not removed or impaired and that the only act committed was the removal of the crowns which had been cemented to the teeth. There was no maiming or disfigurement of the teeth or of any part of the body. It could not be successfully argued, the court continued, that a plate of false teeth, which is frequently removed for long periods of time, is in fact a part of the body. If two teeth should be removed from the jaw of a living person and two crowns should be fashioned by a dentist in such manner that they could be used and readily removed, it could not be seriously argued, the court thought, that the two false teeth would become a part of the body. The argument that the placing of cement in the false teeth to make them adhere to the natural teeth would result in the false teeth becoming a part of the human body seemed to the court equally unsound.

The appellate court, therefore, reversed the judgment of conviction.—*People v. Bullington (Calif.), 80 P. (2d) 1030.*

Hospitals: Liability for Injury to Pay Patient in County Hospital.—Twin Falls County, Idaho, erected and operated a county hospital in which pay patients were admitted. The plaintiff, a pay patient, was admitted to the hospital and an appendectomy was performed on her by her physician. After the operation, the physician prescribed an injection of physiologic solution of sodium chloride to be administered by a special nurse. A hospital employee gave the nurse a container containing a liquid similar in appearance to physiologic solution of sodium chloride but which actually contained boric acid. The special nurse injected the solution and injury to the plaintiff resulted. Thereafter the plaintiff sued the county to recover damages for her injuries. The trial court dismissed the suit and the plaintiff appealed to the Supreme Court of Idaho, which reversed the judgment of the trial court dismissing the plaintiff's suit. *Henderson v. Twin Falls County* (Idaho), 50 P. (2d) 597, 101 A. L. R. 1151; abstracted, J. A. M. A. **106**:1228 (April 4) 1936. The case was tried a second time and the trial court gave judgment for the plaintiff and the defendant county appealed to the Supreme Court of Idaho.

A physician who treated the plaintiff after her injury was called as a witness in her behalf and testified, on direct examination, as to the nature, character and probable lasting effect on her health of the injection of the solution of boric acid. He exhibited to the jury the scars on the plaintiff's leg caused by the injection of the solution. His direct examination was concluded late in the afternoon and the court was adjourned until the next morning. During the night the witness died. The following day, the defendant asked the court to declare a mistrial on the ground that it had, without fault on its part, been deprived of its right to cross-examine the witness. This motion was denied, whereupon the defendant moved that all the testimony of the witness be stricken from the record. The trial court granted this motion and very carefully instructed the jury not to consider any of the testimony. On appeal, the defendant insisted that the testimony of the physician was of such a nature that its rights could not be protected by striking the testimony and by instructing the jury that it be disregarded. It was the duty of the trial judge, said the Supreme Court, to listen carefully to the direct examination of the physician and to observe the attention given his testimony by the jurors and its apparent effect on their minds. After the physician died, and when the question was presented as to the effect of his direct examination on the jury, the trial judge knew, as well as any one could know, whether or not the defendant's rights would be protected by striking the testimony and by admonishing the jury to disregard it. The Supreme Court could see no reason to do otherwise than to place its stamp of approval on the action of the trial judge.

After reviewing all the assignments of error presented by the defendant, the Supreme Court was unable to discover anything that would warrant it in reversing the judgment for the plaintiff. The jury found, the court pointed out, from ample evidence that the plaintiff suffered grave injuries which were caused by the negligence of the defendant's agent while she was a pay patient in its hospital. The judgment of the trial court was therefore affirmed.—*Henderson v. Twin Falls County (Idaho), 80 P. (2d) 801.*

Society Proceedings

COMING MEETINGS

American Association for Thoracic Surgery, Los Angeles, July 5-7. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

American Association of Industrial Physicians and Surgeons, Cleveland, June 5-8. Dr. V. S. Cheney, Armour and Company, Union Stock Yards, Chicago, Secretary.

American Neurological Association, Atlantic City, N. J., June 5-7. Dr. Henry A. Riley, 117 East 72d St., New York, Secretary.

American Ophthalmological Society, Hot Springs, Va., June 5-7. Dr. Eugene M. Blake, 303 Whitney Ave., New Haven, Conn., Secretary.

American Orthopedic Association, Buffalo, N. Y., June 5-8. Dr. Ralph K. Ghormley, 110 Second Ave. S.W., Rochester, Minn., Secretary.

American Physiotherapy Association, Denver, June 25-30. Mrs. Eloise T. Landis, 2065 Adelbert Road, Cleveland, Secretary.

American Proctologic Society, Brooklyn, N. Y., June 25-27. Dr. Curtice Rosser, 710 Medical Arts Bldg., Dallas, Texas, Secretary.

Maine Medical Association, Poland Springs, June 25-27. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

American Heart Journal, St. Louis

17: 259-386 (March) 1939

Earliest Known Reference to the Heart and Circulation: The Edwin Smith Surgical Papyrus, Circa 3,000 B. C. W. W. Hamburger, Chicago.—p. 259.

Prognosis of Bundle Branch Block. L. F. Bishop Jr. and G. A. Carden Jr., New York.—p. 275.

*Role of Treatment of Syphilis in Prevention of Cardiovascular Involvement. W. P. Thompson, Los Angeles; W. J. Comeau and P. D. White, Boston.—p. 286.

Effect of Certain Pure Digitalis-like Glucosides on the Frog's Heart. A. G. Macleod, New York.—p. 294.

Effect of Acetyl-Beta-Methylcholine on the Frog's Heart. A. E. Cohn and A. G. Macleod, New York.—p. 305.

*Treatment of Deep Thrombophlebitis and Chronic Leg Ulcers with Acetyl-Beta-Methylcholine Chloride Iontophoresis. R. A. Sokolov and M. P. Meyers, Detroit.—p. 316.

Papaverine Hydrochloride: Its Questionable Value as Vasodilating Agent for Use in Treatment of Peripheral Vascular Diseases. D. Littauer and I. S. Wright, New York.—p. 325.

Observations on Genesis of Renal Hypertension. L. N. Katz, M. Friedman, S. Rodbard and W. Weinstein, Chicago.—p. 334.

Supernormal Phase of Recovery in Man. D. Scherf, New York, and A. Schott, London, England.—p. 357.

Prevention of Cardiovascular Syphilis.—A statistical evaluation of the antisyphilitic therapy of 260 persons in relation to the later (fifteen to twenty-five years) development of cardiovascular syphilis is presented by Thompson and his associates. They attempt to supply more concrete information on the relationship of the amount of early antisyphilitic therapy to the incidence of cardiovascular involvement. Nineteen persons had cardiac disease of other than syphilitic etiology. Of the remaining 241 patients, eighteen (7 per cent) had definite cardiovascular syphilis and eight (3 per cent) had probable aortitis. In 190 subjects (80 per cent) the heart and aorta were normal, while twenty-five (10 per cent) had questionable dilatation of the aorta. These data agree with those of certain other observers with regard to the incidence of cardiovascular syphilis, for an incidence of 10 per cent (3 per cent probable aortitis and 7 per cent definite cardiovascular syphilis) was found. The grade of treatment showed little difference in the clinical groups except for persons with definite cardiovascular syphilis. All of these patients had inadequate early treatment and in all but one instance the late treatment was no better. The data, the authors state, give some support to their clinical impression that adequate treatment of syphilis tends to prevent the later clinical manifestations of cardiovascular syphilis.

Thrombophlebitis and Iontophoresis.—Acetyl-beta-methylcholine chloride iontophoresis was employed by Sokolov and Meyers in the treatment of nineteen cases of thrombophlebitis of the deep veins and thirteen cases of chronic leg ulcers of various origin. Some of the patients were from the outpatient department while others were private patients referred to the peripheral vascular department of the hospital. The majority of the patients were ambulatory. The shortest duration of the thrombophlebitis among the patients treated was eight days, the longest thirty-two years. Improvement was observed in eighteen of the nineteen cases. The majority of the patients were able to return to full-time work, some at hard manual labor. Others were only partially rehabilitated. In one patient pain and disability, which had been present for thirty years, disappeared completely. Many of the patients had had various other forms of treatment over a period of years without relief. The most definite improvement took place in instances in which the disease was of short duration. When the disease had been present for a number of years, improvement was slow and less dramatic. Improvement may not manifest itself until several treatments have been given. It is not unusual, especially in the cases of old chronic phlebitis, to see no alteration in the disease process until a considerable period has elapsed and then suddenly to observe beneficial changes taking place. In fresh postoperative cases the results were at times quite dramatic. One precaution which was observed in treating open lesions of the skin by iontophoresis was that the ulcerated area itself was covered with a thin piece of rubber sheeting. If this is neglected the current is likely to concentrate at the point of ulceration, which may cause pain and further destruction of tissue. Of the thirteen cases of chronic leg ulcers, twelve lesions had healed completely and the thirteenth lesion was healing rapidly when last observed.

American Journal of Cancer, New York

35: 327-490 (March) 1939

Structure, Nature and Classification of the Cerebellar Astrocytomas. P. C. Bucy and W. A. Gustafson, Chicago.—p. 327.

Comparison of Effect of a Homologous Tumor Material and the Duran-Reynals Factor on Tumor Growth. A. E. Casey, St. Louis.—p. 354.

Production of Transplantable Carcinoma and Sarcoma in Guinea Pigs by Injections of Thorotrast. L. Foulds, London, England.—p. 363.

Sarcoma 37 and the Virus Problem. W. H. Woglom, New York.—p. 374.

Influence of Roentgen Radiation on Immunity to Shope Fibroma Virus. J. Clemmesen, Leeds, England.—p. 378.

Further Studies with Seedlings on the Question of Wavelength Dependence of Radiobiologic Reactions. P. S. Henshaw and D. S. Francis, New York.—p. 386.

Effect of Oil of Wintergreen on Spontaneous Tumors of the Mammary Gland in Mice: VII. Liquefaction of Spontaneous Tumors of Mammary Gland in Mice by Heptyl Aldehyde. L. C. Strong, New Haven, Conn.—p. 401.

Contorted Mitosis and Superficial Plasmagel Layer. W. H. Lewis, Baltimore.—p. 408.

*Rhabdomyosarcoma of Diaphragm: Case Report. T. M. Peery, Washington, D. C., and W. A. Smith, Charleston, S. C.—p. 416.

Experimental Production of Adenoma of the Pituitary. Isabella H. Perry and Margot Szabo Lockhead, San Francisco.—p. 422.

Carcinogens and Planarian Tissue Regeneration. S. E. Owen, H. A. Weiss and L. H. Prince, Hines, Ill.—p. 424.

Rhabdomyosarcoma of Diaphragm.—Peery and Smith report a case of malignant tumor of the diaphragm (rhabdomyosarcoma) in a Negro boy 14 years of age. The observations at necropsy are discussed. The tumor appeared to metastasize entirely by the lymphatic route. This is apparently the tenth case of primary tumor of the diaphragm on record, the sixth case of malignant tumor primary in the diaphragm, and the second case in which the parent tissue was voluntary muscle. Most of the previously reported cases occurred in women in the fourth decade of life. The present patient is apparently one of the youngest patients on record.

Slow Lactose Fermenters in Water Analysis. M. McCrady, Montreal.—p. 261.
Id. Anna Dean Dulaney and E. F. Smith, Memphis, Tenn.—p. 266.

Diphtheria Immunization.—Volk and Bunney compare the immunization value of one dose of alum precipitated toxoid and two doses of fluid toxoid at four months, one year and two years after injection; and a comparison of two doses of alum precipitated toxoid and three doses of fluid toxoid at four months after injection. Most of the children (7,347 from 119 schools) were from rural communities in Saginaw County, Mich. The immunity response was followed by blood titrations only. The authors concern themselves solely with the antitoxin response to different immunizing procedures. They do not attempt to prove that any one procedure is the procedure of choice for routine immunization against diphtheria. The fact that no abscesses or severe reactions have followed the two injections of alum precipitated toxoid augurs well for the future of this method of immunization. In the increasing order of the response that the several diphtheria immunization procedures induce, the authors state that they are, under the conditions of their study, one dose of fluid toxoid, two doses of fluid toxoid at intervals of three weeks, one dose of alum precipitated toxoid, three doses of fluid toxoid at intervals of three weeks and two doses of alum precipitated toxoid at intervals of three weeks.

Gastritis and Ulcer.—From their x-ray and gastroscopic study of peptic ulcer and chronic gastritis, Templeton and Schindler conclude that chronic gastritis, diagnosed easily through the gastroscope, can rarely be diagnosed with certainty by present x-ray methods. This is particularly true of the superficial and atrophic forms. Usually gastric ulcer can be diagnosed equally well by the two methods but occasionally an ulcer may be seen by one method and not by the other. It follows that the two methods should be used together when possible. When an ulcer is located so that the gastroscopist can see it, gastroscopy is the method of choice for following the course of healing under treatment. However, the course of healing can also be followed roentgenologically. Gastroscopic evidence of gastritis is not present in all cases of gastric or duodenal ulcer. The antral narrowing sometimes accompanying gastric ulcer presents gastroscopic evidence of gastritis. Inflammatory changes in the deeper layers of the wall of the stomach may give x-ray evidence of gastritis but no gastroscopic evidence.

Treatment of Acute Pneumonias with Roentgen Rays.—Powell has employed roentgen therapy in 105 cases of lobar pneumonia and in thirty cases of bronchopneumonia. Five of the patients with lobar pneumonia and four of those with bronchopneumonia died, giving a mortality of less than 5 per cent for the former and 13 per cent for the latter. Specific immune serum has been used on only three patients, two of whom died. The technic is to give from 250 to 350 roentgens, using 135 kilovolts, 3 mm. of aluminum filter and a skin target distance of 40 cm. As soon as the diagnosis is made, treatment is given anteriorly or posteriorly over an area a little larger than the involved portion of the lung. A definite leukopenia such as is found in some postinfluenzal pneumonias is the only contraindication to roentgen treatment. If the temperature has not returned to normal or below within thirty-six hours after the first roentgen treatment, a second treatment of 200 roentgens is given over the opposite cutaneous area. When roentgen treatment is given before consolidation is complete it may spread, but the patient shows the usual clinical improvement, and the temperature, pulse, respiration and leukocyte count return to normal. A few cases with mixed infection have required a third or fourth treatment, successively smaller doses of course being given. In mixed infections recovery by lysis is more apt to occur after an initial drop from the high temperature to a moderate elevation above the normal. Bronchopneumonia seems more variable in its response to radiation therapy. The author's patients have been treated in all stages of the disease, from the first to, in one case, the eleventh day. Most of the patients show relief of distress and general symptomatic improvement within a few hours and more than one third of them, he states, have shown a drop in temperature to normal or below within thirty-six hours after the treatment. The temperature of a number of patients has returned to normal in less than twelve hours after treatment. The author uses digitalis only when there is definite cardiac decompensation. He uses oxygen when there is cyanosis or when the respiratory rate is high enough to be exhausting to the patient. Metrazol is used as a respiratory and peripheral circulatory stimulant. Morphine or dilaudid as indicated is given for pain. High fever is usually controlled by ice caps and cold colon flushes. The author believes that, even if the mortality had not been reduced so much, the use of roentgen therapy in these cases would be justified by the relief of anxiety and discomfort experienced by the patients.

Hypertension in Bright's Disease.—Mosenthal and Lander point out that the elevation of blood pressure characteristic of chronic Bright's disease is usually believed to occur in two ways: without any renal involvement (primary or essential hypertension) or as the result of renal insufficiency (secondary

hypertension). However, the development of increased arterial tension before impairment of renal function is present occurs commonly in cases of chronic diffuse glomerular nephritis, the initial, dominant, often sole sign of which is albuminuria. The study of 124 cases shows that 36 per cent of the patients had a normal blood pressure, 19 per cent had an elevation of blood pressure associated with marked renal insufficiency and 45 per cent had hypertension with little or no renal insufficiency. This shows chronic diffuse glomerular nephritis the initial symptom of which is albuminuria as being albuminuria first, hypertension next and, finally, renal insufficiency. Hypertension of marked degree may manifest itself in chronic Bright's disease characterized at the onset only by albuminuria, even in the absence of or coexistence of no more than a slight degree of impairment of renal function. The hypertension occurring in patients with albuminuria often is the cause of death. The most common sequence of events when albuminuria exists that the authors have observed was the evidence of hypertension followed by signs of renal insufficiency and, if the patient survived the effects of the increased arterial tension for a sufficient period, the impairment of renal function would become more marked and retention uremia then was the cause of death. There were some cases of albuminuria that over a period of years (36 per cent) did not give evidence of either hypertension or impairment of renal function. The authors do not believe that a high protein diet is a cause of hypertension. Hypertension may be brought about by a latent renal insufficiency which is not shown by the usual clinical tests, since the latter indicate a diminution of renal function only when 50 per cent or more of the renal tissue becomes inactive, or the progressive involvement of the kidneys incident to the nephritis may, through autolysis, produce a pressor substance akin to the "renin."

Hepatic Function in Arthritis.—In a previous study Rawls and his colleagues found that 73 per cent of 100 patients with rheumatoid arthritis gave evidence of hepatic dysfunction, as determined by the azorubin S hepatic function test. Being aware that no single test gives an indication of all the functions of the liver, these observations prompted them to continue this study, using other tests for comparison. The results obtained in fifty unselected cases showed that a high proportion of patients with rheumatoid arthritis had evidence of hepatic damage as determined by the azorubin S, hippuric acid and bilirubin excretion tests. The icterus index, galactose tolerance and albumin-globulin ratio were considered unsatisfactory. The hippuric acid test and the albumin-globulin ratio gave the highest proportion (62 per cent) of abnormalities. When the azorubin S test showed abnormalities, so did one or more of the other tests. Because of this agreement and because it agreed more closely with the clinical evidence, the azorubin S test was considered most suitable for detecting chronic hepatic damage. Technical errors and lack of specificity in the different tests make it desirable that more than one test be used.

Incidence of Otitis Media in Scarlet Fever.—In a review of reliable sources from the literature, Wesselhoeft accumulated 371,778 cases of scarlet fever in which the average incidence of suppurative otitis media is 12 per cent. In a study of 10,000 cases on his own service, the incidence was also 12 per cent. Within the last few years an incidence of about 12 per cent has been reported from Stockholm, Rome, Boston and Los Angeles. Thus climate, which plays an important part in the morbidity of scarlet fever, appears to exert no influence on the incidence of involvement of the middle ear. The age of the patient exerts a definite influence on the frequency of this complication, its incidence being about 40 per cent in the first years of life. Otitis media is more frequent in winter than in summer. Diphtheria and measles when associated with scarlet fever augment the frequency of otitis media. Isolation lowers the incidence. While a previous tonsillectomy reduces the likelihood of scarlet fever, the absence of tonsils cannot be shown to lower the incidence of otitis media. Paracentesis does not materially reduce the incidence of surgical mastoiditis. Early treatment with serum appears to have a favorable effect on the incidence of otitis media. The administration of concentrated cod liver oil to patients with scarlet fever does not appear to lower the incidence materially. While the administration of sulfanilamide appears to be of distinct value in the event of septicemia, further hospital investigations are necessary before this drug should be recommended as a routine prophylactic measure for the aural complications of scarlet fever.

Malignant Tumors of Nasopharynx and Paranasal Sinuses. N. S. Weinberger, Sayre, Pa.—p. 203.

Nicotinic Acid and the Eighth Nerve.—Selfridge has used nicotinic acid, nicotinamide and quite recently sodium nicotinate in the treatment of some thirty cases of high tone deafness. The ages of the patients ranged from 21 to 77 years. In many the results are striking; in all cases in which the audiogram shows a gradual decline of the tone scale, use of these fractions is justified; for, while the improvement in the audiometric curve may not be great, the physical and mental improvement is sufficient justification. Indeed, any measures tending to ward off senescence are justifiable, and evidence is slowly accumulating that several components of the vitamin B complex play a definite part in the advancing of age.

Auditory Acuity in a School for the Deaf.—According to Hughson and his associates, complete lack of response to auditory stimulation is a rare condition, as 95 per cent of the 460 children studied at the Pennsylvania School for the Deaf responded to at least one tonal frequency by air conduction in one ear and 85 per cent in both ears. In the majority of these children the loss of hearing is bilateral and approximately equal in the two ears. Sex is not a significant factor. Since age is not related to the degree of loss, the type of deafness dealt with does not seem to be progressive. Fifty-four per cent of the children were said to be born deaf. The percentage of children who presumably became deaf after birth is highest at 1 year of age and decreases rapidly at each consecutive year. No difference

in acuity of hearing could be found between the children who were born deaf and those with acquired deafness. The deafness developing after birth has been attributed to numerous pathologic conditions, among which meningitis is the most frequent. This disease was stated to be the cause for deafness in 17 per cent of the children. Meningitis together with trauma of the head, measles, otitis media or scarlet fever was given as the cause of deafness for almost one half of the children. A significant number of the children examined were found to have enough residual hearing either by air or by bone conduction to warrant some rational effort toward therapeutic relief.

Pathologic Effects of Certain Glycols.—In studying the changes that occur in rats, rabbits and guinea pigs to which ethylene glycol (glycol), diethylene glycol (diglycol), propylene glycol and some of their derivatives had been administered Kesten and his associates found that (1) ethylene glycol and ethylene glycol diacetate may cause deposition of oxalates in the kidneys and mild renal insufficiency, (2) propylene glycol is relatively harmless, especially when given by mouth, large intravenous doses being necessary to cause hemoglobinuria and casts, and (3) diethylene glycol, the methyl, ethyl and butyl ethers of diethylene glycol, dioxane and dipropylene glycol are all capable of causing profound degeneration of renal epithelium leading to uremia. The molecules of diglycol and its ethers, of dipropylene glycol and of dioxane contain an ether linkage between two glycol molecules. Dioxane possesses two such linkages, which may in part account for its relatively high toxicity. The molecules of ethylene glycol, ethylene glycol diacetate and propylene glycol lack this particular type of ether linkage. The ether linkage between two glycol molecules may be responsible for the hydropic degeneration of the epithelium of the convoluted tubules and of the hepatic cords. The main feature of the compounds causing hydropic degeneration of the kidney is the extensive character of the damage wrought. In each experiment one or more of the animals was apparently unaffected by the drug, but in the injured animals the lesions were usually maximal. The animals that received diglycol and its ethers, dioxane and dipropylene glycol died usually as a result of the damage to the convoluted tubules, in uremia. Appreciable amounts of the several chemicals must be given to produce demonstrable changes in the animals. In no instance was less than 1 cc. per kilogram of body weight effective.

Changes in Musculature in Chronic Appendicitis.—Goldner states that in chronically inflamed appendixes there are morphologic deviations of the two muscular layers, with attenuation or thickening, disappearance and the production of supplementary fibers. Aberrant fibers appear ectopically, forming median coats, surrounding lymph follicles or lying in the fibrous capsule of the submucosa. These structural changes are frequently seen in chronic appendicitis, fairly often in the subacute inflammation that signalizes early chronic appendicitis and rarely in acute appendicitis and in normal appendixes. Their presence denotes past attacks that have stimulated the production of capillaries and histiocytes. They exist even when other cardinal signs have subsided. Functional changes in the form of abnormal contraction should correspond to these structural abnormalities of the musculature, which would in part explain the pathogenic mechanism of appendicitis. Abnormal contraction may be as important etiologically as changes in the rigid connective tissue framework, which also shows lesions of past attacks. Aberrant fibers have a special histogenesis. Preformed or newly formed capillaries disappear. Although the majority of aberrant muscular structures appear to be permanent, others may fall prey to sarcolysis or to rearrangement. The lytic forces involved are supplied by histiocytes.

Operation for Venereal Lymphogranuloma.—In order that local measures of treatment may be carried out without danger of peritonitis Warthen devised an operation, which he has performed successfully on ten patients with proved venereal lymphogranuloma. The procedure, in brief, is obliteration of the culdesac by chemical irritation and suturing, followed by a double-barreled colostomy. The patients have recovered and have been benefited by the procedure. In one of the early cases a small ventral hernia developed at the site of the colostomy. In the later cases greater care has been taken in suturing the aponeurosis of the external oblique muscle through the defect in the mesosigmoid and no hernia has occurred. The closure of the culdesac has permitted dilation of the stricture without danger of peritonitis, and the diversion of the fecal current has resulted in relaxation of the strictures. If necessary, further operative procedures on the stricture may be carried out through the rectum with relative safety. The author states that this is a preliminary report, for operation in the earliest case was done only eighteen months ago, and none of the colostomy openings have been closed.

Acute Segmental Appendicitis.—From experimental studies on rabbits and twenty cases of human segmental appendicitis (proximal, central and distal types) Felsen and Lewis find from an anatomicopathologic standpoint that there are two obvious

points of similarity between segmental appendicitis in the rabbit and in man. First, the vascular supply in both is of the terminal type. Second, the clearly defined segmental lesions produced by vascular ligation in the rabbit resemble both grossly and microscopically those observed in man. The possible point of divergence lies in the pathogenesis, in whether all segmental lesions in the human appendix are due to vascular occlusion. The authors attempt to reconcile the many divergent opinions on the subject of appendicitis with their hypothesis that acute segmental appendicitis in man is due to vascular occlusion. After discussing the many theories, they conclude by stating in defense of their hypothesis that, whether the blood vessels are affected by systemic toxins or by bacteria from a distant focus or whether they are obstructed secondarily by distention of the lumen, by angulation or by foreign bodies, the theory of vascular occlusion as the cause of segmental appendicitis seems plausible. They believe that the applicability of their theory to the pathogenesis of appendicitis in general is also suggested by the data that they cite.

Detection of Two Typhoid Carriers.—The histories of two typhoid carriers are cited which Wyllie believes illustrate the missed type of carrier and the development of the carrier condition following a clinical attack of the disease. In the first case, the history suggests that the patient was the source of infection for her husband and two sons at different intervals. Conclusive evidence that she infected her youngest son is furnished by Craigie's bacteriophage tests, which show that the strains of Bacillus typhosus isolated from the mother and the son are identical and belong to the same group. The need for reexamination at intervals of three, six, nine and twelve months following the illness is shown by the second carrier. The patient, an institutional inmate, had typhoid in April 1936 and a month later another case developed. Both patients were investigated and suspicion fell on the first case as directly responsible for the second. The organisms isolated from both cases proved identical by bacteriophage tests, being type C strains. The serologic results of blood samples from the first of these two cases, which were examined frequently, suggested a possible carrier condition and this was confirmed by fecal isolation of the specific organism a year following the illness.

Progressive Myopia.—Thompson and Nugent believe that they have developed a treatment for progressive myopia which practically covers every phase of the etiology involved. They have found it extremely successful in all cases of axial progressive myopia; less so in the more complicated types, but worth trying in all. The first step in the treatment is the making of the prescription for glasses. The total error is ascertained. Then from 20 to 25 per cent of the sphere is removed, and the prism is found by adding prisms base in until diplopia is produced. Now the prism is neutralized until monocular vision is accomplished. The remaining prism is used base in, half over each eye. The next step is to place the lenses as near to the patient's eyes as is possible without their touching the cilia. This is for the scientific reason that, the longer the focal distance, the larger the object appears to a myopic eye, and therefore the less the strain on it. The third step consists of special exercises with the myoculator. The patient is seated 4 feet from the machine, wearing the proper prescription and three diopters of prism base in over each eye in addition. The eyes should be exercised for ten minutes, three times a week. The time may be increased, slowly, to twenty minutes. The fourth step is a request for special class work, special large type in the books read and the scientific use of good lighting, either natural or artificial. All use of the eyes for close work must be carefully supervised and a time limit used. The fifth step is the compilation of a diet list which will give the patient a properly balanced vitamin intake. The last step is called "medication" and consists of cod liver oil and iron, quinine and strychnine for rebuilding the muscle power involved. The authors conclude that, whatever else may be used in the treatment of myopia of any type, the eyes should be prevented from converging, and for this they advise base in prisms.

Amphetamine Sulfate in Severe Depressions.—Finkelman and Haffron used amphetamine (benzedrine) sulfate in the treatment of fifteen patients; five were classified as in the depressed phase of manic-depressive psychosis and seven as having involutional psychoses, one was a mixed type of manic-depressive psychosis and two were severely depressed but their behavior did not fit any of the nosologic entities. The duration of the treatment varied between three weeks and three months. The amphetamine sulfate was administered in the early part of the day, in divided doses, the dosage ranging from 20 to 60 mg., administered in the form of 10 mg. tablets. One patient (involutional psychosis) improved markedly after amphetamine was administered for three weeks. The other fourteen patients showed no favorable response. During the administration of the drug, however, two of the patients recovered two and three months, respectively, after treatment was discontinued. These were cases

of manic-depressive psychosis. Three patients were definitely affected adversely by the treatment. Another depressed patient became restless and irritable and acquired a suicidal tendency which ceased after the medication was discontinued. In a third patient the treatment was discontinued because the patient became combative. Amphetamine sulfate is a useful drug and is of value in postencephalitic parkinsonism, narcolepsy, mild depressed states and chronic exhaustion, but it is of no value and may be harmful in severe depressions.

*Studies on Hypersensitivity to Catgut as Factor in Wound Disruption. K. L. Pickrell, Baltimore.—p. 195.

Hypersensitivity to Catgut and Wound Disruption.—Pickrell states that only three cases of disruption of surgical incisions sutured with catgut have occurred at the Johns Hopkins Hospital during the last two years. Approximately 4,000 incisions have been closed with catgut during this time. Each of these patients was tested for local sensitivity immediately following disruption by intradermal injection on the volar surface of the forearm of 0.1 cc. of catgut extract, with a physiologic solution of sodium chloride control, and in addition with 0.1 cc. of Kraissl's plain and chromic extracts. Similar quantities of extract diluted 1 to 10 were injected intracutaneously in the opposite arm. The tests, performed immediately after disruption, were negative. Furthermore, negative results were obtained on 100 patients tested preoperatively and postoperatively in a similar manner at daily intervals for several days. The same patients were again tested from three to four weeks after operation, when the greater part of the catgut is probably absorbed, and the tests were negative. It has been stated (Kraissl) that "it is possible to sensitize guinea pigs to catgut and to produce disruptions of laparotomies with this material." It has been impossible for the author in his experiments to sensitize either guinea pigs or rabbits to commercial catgut or to an extract from catgut. Wounds did not disrupt in rabbits or guinea pigs which had been previously treated with catgut when proper aseptic precautions were observed. Although catgut implanted intradermally in rabbits and guinea pigs caused an inflammatory response, the leukocytic emigration was no greater than in those animals which had been previously treated with catgut or catgut extract. Therefore the author concludes that although catgut, like any other suture material, acts as a foreign body and causes a slight leukocytic response it does not act as an antigen inducing a hypersensitive state.

Effects of Sulfanilamide on Brucellosis.—Menefee and Poston studied the in vitro action of sulfanilamide and related compounds on Brucella organisms, the in vitro action of sulfanilamide and antibrucella serum and the action of sulfanilamide on experimental brucellosis in the guinea pig. The results of the three varieties of Brucella (melitensis, abortus and suis) organisms show no essential differences after thirty-six hours of incubation between the cultures with sulfanilamide and the controls. After thirty-six hours, however, the bacteriostatic effect of the sulfanilamide was definitely apparent. The results are similar to those obtained by Long, who showed the in vitro bacteriostatic effects of sulfanilamide on streptococci and other organisms. The work of Francis, who was able to sterilize cultures of a strain of Brucella abortus by the addition of small amounts of sulfanilamide, was not confirmed by the authors. They state that the good results obtained by him may have been due to the small inoculum used in his experiments. Of the related compounds tested only one (p,p' diaminodiphenyl sulfoxide) had a greater in vitro bacteriostatic action than sulfanilamide on Brucella melitensis. The bacteriostatic effect of serum and sulfanilamide on Brucella melitensis was less efficient than sulfanilamide alone. For studying the effect of sulfanilamide on experimental brucellosis forty healthy guinea pigs were injected intraperitoneally with 1,000,000,000 organisms of a culture of Brucella melitensis recently isolated from the blood of an acutely ill patient. Five days after injection one half of the animals were given sulfanilamide for ten days, receiving daily 60 mg. per kilogram of weight. The dose was then halved and continued for ten more days. Thirty-five days after inoculation all the animals were killed and carefully examined, and cultures of their spleens were made on liver infusion agar. Agglutinins and opsonocytophagic powers were present in all the guinea pigs, but at the end of the experimental period the average agglutinin titer of the treated group had fallen and the opsonocytophagic reaction had increased. The agglutinin titer of the untreated group remained high till the end of the experiment, and the opsonocytophagic reactions were only moderately strong. Brucella was isolated from nineteen of the twenty untreated guinea pigs and from only one of the treated animals. No marked serologic reaction developed in this guinea pig. The authors believe that their experimental observations support the clinical ones in suggesting that the bacteriostatic action allows the normal defense mechanisms of the body to cope adequately with the invading bacteria.

Acute Ethylene Dichloride Poisoning.—Wirtschafter and Schwartz report three cases of industrial poisoning resulting from exposure to ethylene chloride vapor. The men were employed in a knitting factory and they were poisoned while cleaning a shipment of yarn. They had not had any previous

exposure to ethylene dichloride. Four hours after the exposure began, the men became dizzy, were nauseated and vomited profusely. They complained of weakness and trembling. The men were removed from exposure immediately after the onset of nausea and were hospitalized one hour later, since their vomiting continued unabated. A severe dermatitis of the hands occurred as the result of direct contact with the liquid. Hepatic damage was evident by the presence of extremely low blood sugar levels. Leukocytosis occurred in each case. No evidence of renal damage was observed. Because of its relaxing effect on smooth muscle, 10 per cent calcium gluconate solution was administered intravenously to each patient on admission to the hospital. Prompt relief of the epigastric cramps occurred. Vomiting also subsided, so that the men were able to take fruit juices within a few hours. Fluid was therefore not administered parenterally. The tremors disappeared shortly after admission. The following day the administration of a high calcium, high carbohydrate diet was instituted. Occasional nausea persisted for several days. Bland ointments were applied to the hands and the severe dermatitis improved slowly over a period of weeks. The patients were discharged one week after admission, with the advice that the high carbohydrate diet be continued for some time. At the time of discharge the men felt entirely well except for the condition of their hands. The clinical symptoms in these cases were similar to those produced by the other chlorinated hydrocarbons when inhaled in fairly high concentration. The absence of unconsciousness was undoubtedly due to the fact that exposure was terminated before sufficient vapor had been inhaled.

Sulfapyridine.—MacColl used sulfapyridine in the treatment of thirteen cases of various types of pneumonia, nine of bronchopneumonia, three of osteomyelitis, three of meningitis, two of ruptured appendix and one each of cellulitis of the hand and shoulder, impetigo neonatorum and epidermolysis bullosa. The most effective use of the drug appeared to be in pneumococcic infections. Improvement was observed within forty-eight hours. The total leukocyte count seemed to be the best indicator of progress, since a delay in resolution and spread of the process appeared to occur when the count remained high. This suggests that specific antiserum may be of value when the patient's antibody response is slow. In bronchopneumonia the drug was of benefit when other treatment failed. The infections treated were caused by beta hemolytic streptococci and hemolytic Stapylococcus aureus. The miscellaneous group of conditions treated suggests that the drug may have wider applications and deserves further study. Toxic effects such as vomiting, cyanosis, methemoglobin formation and a fall in hemoglobin during treatment indicate that the same caution must be employed as when sulfanilamide is used. Sulfapyridine is effective in smaller doses and in lower concentrations than sulfanilamide. In almost all cases the administration of the drug has been accompanied by a lowering of the temperature. This has been so constant that an antipyretic effect is suggested.

Oils as Substitutes for Butter Fat.—Frontali studied the absorption of various fats in pathologic conditions in infants in whom the utilization of butter fat is usually poor, as in celiac disease. From his studies and those of his collaborators, both clinical and experimental, in both normal infants and in those who have a diminished tolerance for fats, he is led to conclude that an oil-flour food or dry oil-milk in which olive oil is substituted for butter permits an efficient utilization of fats (96.26 per cent), which approaches that of pure triolein (97.77 per cent), is well tolerated and leads to a regular and continuous increase in weight, while a similar food in which butter is used instead of olive oil, other circumstances being equal, gives inferior results. In the preparation of the food, sufficient quantities of butter can remain after the centrifugation of the milk or the vitamins A and D can be added in measured quantities to the oil-flour food or to the dry oil-milk.

Morphine as Metabolic Stimulant.—Barbour and his colleagues confirm the calorigenic action of morphine, deduced by Barbour, Gregg and Hunter, from reduction in metabolic rate on withdrawal of dogs from the drug. The degree of stimulation appears unrelated to the presence or extent of chronic morphinism. During the first month of this condition the metabolic peaks averaged 16 per cent, and during the second to fifth months 19 per cent. The average resting metabolism for the entire twenty-four hours, by sampling at different times, can be estimated at 10 per cent above normal in the second to fifth months of morphinism. The peak of stimulation appears sooner after the daily injection as tolerance to the quieting effect of morphine develops. Morphine, independently of neuromuscular activity, exerts marked influence as a metabolic stimulant.

Mare Serum in Endocrine Dysfunctions of Women.—Kennedy and Shelton treated ten cases of amenorrhea and three cases of menorrhagia with pregnant mare serum hormone intramuscularly. No gross pathologic changes in the pelvis were found in any of these women. The work of Davis and Koff, in which they produced ovulation in the human female, was accomplished with the intravenous use of the hormone. Before administration the patients were carefully tested for protein hypersensitivity. The results, particularly in some of the amenorrheas, were sufficiently hopeful to justify mention. Pregnant mare serum exhibits certain definite physiologic differences from preparations of urinary gonadotropic substance. The physiologic studies on animals and human beings indicate that this hormone possesses gonadotropic properties closely resembling those of the anterior pituitary gland. In proper dosage many workers have shown that it is capable of stimulating normal ovarian function. The action in general is similar to that of the various gonadotropic substances. Urinary gonadotropic substances act differently in the human being than they do in laboratory animals and therefore do not fulfil the original hopes entertained for them as a true pituitary type of gonadotropic hormone. The new mare serum hormone seems to fulfil the desired requirement of an anterior pituitary-like gonadotropic substance.

Colloidal Aluminum Hydroxide for Peptic Ulcer.—Rutherford and Emery treated twenty-eight cases of severe peptic ulcer with colloidal aluminum hydroxide. This was given orally or by continuous drip and orally for from three to nine months. The gastric contents were completely neutralized. Relief of pain occurred within twenty-four hours. The drug and the method of treatment were agreeable to the majority of patients. The drug apparently did not alter the body chemistry. This type of treatment is advantageous in patients who do not respond to the usual medical treatment because of a hypersecretion or night secretion, in those in whom peptic ulcer is complicated by nephrolithiasis and in patients in whom alkalosis develops while they are receiving alkaline powders.

Picrotoxin.—Dille summarizes the fifteen cases of barbiturate poisoning treated with picrotoxin that have appeared in the literature. A considerable number of barbiturates and a wide range of doses were involved. Thus far there have been no extensive clinical studies of the use of picrotoxin as an analeptic for depressants other than barbiturates. It may be of value in the treatment of poisoning from chloral hydrate and paraldehyde. There is definite evidence that picrotoxin is definitely dangerous in morphine poisoning. Therefore, before using picrotoxin it is important to know the depressant responsible for the coma. The most conclusive evidence of whether the barbiturates are responsible is their presence *in the blood*, urine or stomach washings of the patient. A simple test available for this purpose is one devised by Koppanyi and his associates. Picrotoxin is generally regarded as a dangerous drug. Its dose is from 0.5 to 2 mg. and it has a narrow margin of safety when used alone. However, pharmacologic experiments and clinical evidence indicate that in the case of barbiturate poisoning much higher doses may be used. It must, however, be administered by divided doses of from 3 to 10 mg. and the total amount administered should depend on the response of the patient. At all times an overdose of the picrotoxin should be avoided, for an attack of convulsions is followed by greater depression. Picrotoxin has been usually administered intravenously during the first part of the treatment at intervals of from twenty minutes to an hour until an increase in respiration and a rise in blood pressure occurs or until slight twitches appear in the facial muscles. Picrotoxin is detoxicated by the body quite rapidly and in order to be effective the amount in the body must be maintained. As the treatment progresses the drug may be administered intramuscularly. Other measures, such as gastric lavage, other *stimulants, oxygen and parenteral fluids*, should be carried out.

Picrotoxin for Barbiturate Intoxication.—A case of barbiturate intoxication in a woman 20 years of age is reported by Stephens and Anderson. The patient took 72 grains (4.7 Gm.) of sodium amytal. This was evidently absorbed, since no emesis occurred. The patient was comatose and displayed signs of marked anoxemia, with cyanosis, reduced respirations and clonic convulsions. After the administration of 156 mg. of picrotoxin over a period of twenty-four hours, together with large quantities of fluid intravenously, the patient regained consciousness and recovered rapidly. Within a few days she was entirely well. This instance furnishes additional evidence of the clinical efficacy of picrotoxin in counteracting barbiturate intoxication. This drug is not employed as a substitute for symptomatic and supportive measures but is used as an active adjuvant to these procedures.

Vitamin C Content of Milk and Vegetable Extracts.—Concepcion and Gargaritano analyzed samples of different kinds of milk, fruit juice and vegetable soup for their vitamin C content by the dye method outlined by Bessey and King. They found that human milk (Filipino) was four times richer in vitamin C than cow's milk and more than two times richer than carabao's milk. The vitamin C content of evaporated milk, when diluted to be equivalent to cow's milk in composition, did not compare favorably with fresh cow's milk. Calamansi (Citrus mitis) and dayap (Citrus aureus) are cheap sources of vitamin C and their use by poor people should be extended. Soup of malungay (Moringa oleifera), kale (Brassica oleracea L.) or petsay (Brassica chinensis L.), prepared by mixing the vegetable with two parts of water by weight, may be used as a milk diluent for infant feeding. They are excellent sources of vitamin C. It is strongly recommended that an additional supply of vitamin C, in the form of calamansi, orange or tomato juice or vegetable soup should be given to infants taking either breast milk or artificial feeding, as a prophylactic measure.

Buccal Lesions Associated with Dietary Deficiencies.—Topping and Fraser studied the occurrence of pathologic changes in the oral cavity in monkeys on selected diets deficient in vitamin A, D, C or B_2. Certain of the dietary deficiencies tested were associated with the development of varying manifestations of gingivitis, stomatitis, periodontal disease and noma. Noma developed in the buccal mucosa only in monkeys receiving diets deficient in vitamin B_2. Comparable animals maintained on adequate diets showed little or no evidence of such oral conditions. In addition, monkeys maintained on a stock diet showed no evidence of gingivitis or stomatitis when material from affected monkeys was transferred directly to them. Diets supposedly deficient in vitamin A were about as efficient in preventing the development of oral lesions as the artificial control diet. In the remaining deficiency groups, however, there is a definite difference in the numbers developing lesions and the severity of these lesions.

Roentgen Treatment of Leukemia.—Harrison and Reeves used roentgen therapy in the treatment of forty-seven cases of leukemia of which three were of the aleukemic, twelve of the lymphatic and thirty-two of the myeloid leukemia type. Sixteen patients are still living. The patients were treated by the local application of the rays, general radiation, the so-called "spray method" and a combination of the two methods. The spray method seems superior in that there is no roentgen sickness and more of the bone marrow as well as the circulating blood is irradiated. Patients receiving spray treatments were symptom free for longer periods of time. In addition, in patients treated by the spray method a resistance to the rays develops slowly and hence can be carried over a longer period. The results

from the spray method (84 per cent living) are better than the results of local treatment (22 per cent) or local and spray combined (56 per cent). The authors do not believe that the spray method is likely to cause serious injury to the bone marrow, resulting in aplastic anemia, if the rays are properly administered by competent roentgenologists. If the dose is kept low and frequent blood studies are made, it is not difficult to get the blood to a normal level. The spray method is, of course, contraindicated in the aleukemic form of the disease. They do not feel that the actual life span of the patient is increased, but the useful period of life is distinctly prolonged. Of the forty-seven cases there was a history of previous severe infection in 47 per cent, lending weight to the infection theory.

Postoperative Pulmonary Atelectasis.—Moore states that in the surgical service of the Cincinnati General Hospital any patient developing a sudden or unexpected elevation of temperature or respiratory rate during the first two postoperative days is suspected of having atelectasis until proved otherwise. If a diagnosis is established, the following procedure is carried out: If not already in use, a tight abdominal binder is applied. The patient is changed from Fowler's position to one in which the pillow is removed and the head is dropped flat, leaving the knees elevated. A chair is placed under the foot of the bed and the patient is turned so that his affected side will be up. The physician then stands behind the patient and places one hand on the uppermost shoulder, rolling the patient slightly forward on his abdomen. This puts the main bronchus in a true vertical position and secures the greatest gravitational effect on the bronchial secretions. The patient is instructed to place his uppermost hand on his abdomen, over his wound, and this is reinforced by the free hand of the physician. Occasionally, simply placing the patient in this position initiates violent coughing, but if coughing is not forthcoming the patient should be encouraged to cough. In the majority of cases the mucous plug will be loosened by the first guarded cough and an uncontrollable cough reflex set up with the production of a sizable quantity of mucus. Coughing is encouraged until rhonchi no longer can be felt by the palpating hand. It is not uncommon for such a patient to volunteer the information "that's all." If this fails or if the patient refuses to cough because of incisional pain, further efforts are aimed at loosening the plug. He is asked to take a few deep breaths. If this fails to produce the plug, a sharp blow on the back will often accomplish the desired result. If these maneuvers fail, inhalations of carbon dioxide are given to increase the depth of respirations and this will frequently loosen the plug. If rhonchi still persist and breath sounds are not coming through the involved lung, the patient is forced to remain in the described position for as long as half an hour at a time. During this period steam inhalation of tincture of benzoin is given. The steam thins out the mucus, and the gravitational effect is enhanced by being allowed to act over a period of time. This entire regimen is not used frequently, as the obstructing mucous plug ordinarily can be produced by simple forced coughing. The author has had a marked uniformity of success in relieving postoperative atelectasis by the foregoing type of postural drainage. The most striking relief has occurred in those cases in which the atelectasis is recognized within an hour or two after onset. The efficacy of postural drainage used at the author's clinic for relieving atelectasis is illustrated by the report of six cases.

Influence of Papaverine on Intestinal Tone.—Bargen and Jackman state that morphine causes an increase in motility and tone of the large and small intestine of man. The constipating effect of morphine may be attributable to the regions of

spasm which it initiates. Papaverine hydrochloride alone or in combination with pantopon has been found of value in relieving the distressing abdominal cramps and frequent purulent, bloody discharges associated with the acute phase of chronic ulcerative colitis and other acute dysenteries. Experimental evidence has substantiated the antispasmodic effect of this papaverine compound. The papaverine compound has certain advantages over morphine sulfate in cases in which it is desired to immobilize or put the intestine at rest.

Tubal Resection for Recurrent Gonorrheal Salpingitis.—Falk and Weitzner offer cornual resection of the tubes as a surgical procedure for the cure of recurrent gonorrheal salpingitis. It involves a minimum of surgical trauma and in 112 of their cases they state that there was no primary mortality or primary pelvic morbidity, the anatomic results were perfect in 70 per cent, good in 14 per cent and fair in 7 per cent, 79 per cent of the patients were symptom free and 21 per cent had slight symptoms, 87 per cent were fit for manual labor and 13 per cent were partially incapacitated, and there were no reoperations for pelvic disease and no readmissions for recurrent salpingitis.

*Vincent's Infection and Its Relation to Subclinical Scurvy. H. M. Williams, Fort Worth.—p. 779.

Relation of Vincent's Infection to Scurvy.—Williams has seen a large number of indigent patients at the Preventive Medicine Clinic and Immunization Station who showed marked signs of gingivitis. Smears taken disclosed Vincent's organisms in abundance. He states that all the patients admitted to this clinic are from families in which the wage earners are unemployed, are employed by WPA or have other low salaried employment. The majority of these are unable to provide sufficient fresh fruits and vegetables or other antiscorbutic foods, and of those who might be able to provide these in sufficient quantities many are unaware of the necessity for these dietary elements or do not place enough importance on the necessity for them. Realizing that there was probably a considerable amount of subclinical scurvy among these people, the author carried out an experiment to determine, if possible, what effect the addition to their diet of a sufficient amount of a pure crystalline vitamin C acid in tablet form would have on the treatment of Vincent's infection in this group. In this way an accurate check on the minimal amount of vitamin C taken by each patient could be made. Only those patients (twenty-two) who were considered to be getting a definite subminimal amount of antiscorbutic foods in their diet were studied. As controls for the experiment, patients with the same requirements as the test group received the same treatment except for the ascorbic acid. The treatment given consisted in the topical application once daily of 7 per cent chromic acid followed by full strength hydrogen peroxide. Saturated solution of sodium perborate was used as a mouth wash and gargle four or more times a day, and one or two, according to age, 25 mg. tablets of ascorbic acid. The patients were visited once or twice each week by a member of the public health nursing staff, who supplied the patients with the necessary supplies and instructed them as to the proper means of treatment. Smears from the gums and throats were made at frequent intervals. The results obtained, although not conclusive, do indicate marked improvement following the use of ascorbic acid in most cases in which a definite vitamin C deficiency was found to exist. Of the twenty-two patients treated all showed either clinical improvement or marked decrease in the relative number of spirillae on smears or both.

Sulfanilamide in Obstetrics.—Hanley and Golenternek tried to determine the value of sulfanilamide in postabortal and puerperal infections. They review 150 cases from the infected obstetrics wards in the Los Angeles General Hospital. In seventy-five of these cases sulfanilamide was used along with any measures in their routine treatment which seemed indicated. The other seventy-five patients were given the same type of treatment except that they did not receive sulfanilamide. Of the seventy-five cases of sepsis treated with sulfanilamide thirty-two showed apparent improvement, such that the period of hospitalization was shortened an average of 2.8 days when compared with the similar group not receiving this drug. In twenty cases the results were called doubtful as there were minor complications and the temperature did not subside at the given time. In the remaining twenty-three cases the results were of no comparative value. However, this group contained all the cases in which the infection had extended beyond the walls of the uterus, with resultant peritonitis, septicemia, pelvic abscess or other complications not directly related to the original infection; thus quick recovery could hardly be expected. No improvement was observed in any case of thrombophlebitis in which the drug was used.

Treatment of Diphtheria with Refined Antitoxin.—Hutchison states that, from January to August 1938, 200 diphtheria patients were treated in Belvidere Hospital with a refined antitoxin prepared by Pope's (1938) process. This antitoxin is prepared by a process of enzyme disaggregation followed by differential heating. The antitoxin was administered without desensitization of the patient, even though fifty of the 200 patients gave a history of previous injection of serum. Patients with cervical adenitis were given chewing gum. There were no reactions when the serum was given by the intramuscular route and only slight reactions when it was given intravenously. There were five deaths, two of which occurred in patients who were moribund on admission and who died within a few hours; the other three were due to cardiac paralysis. The percentage of gravis bacilli in the present series (thirty-one) is high compared with that of Carter in the same area (3.1 and 10.5 in different series) and this makes the 2.5 per cent death rate a strikingly low figure. Chewing gum appears to be useful in adenitis, apparently causing massage of the cervical glands by the action of the jaw in chewing.

Stilbestrol in Menopause Symptoms.—Kellar and Sutherland used stilbestrol, a synthetic estrogenic drug, in the treatment of the menopausal syndrome, senile vaginitis, vulval leukoplakia, secondary amenorrhea and for inhibiting lactation. The results were more or less comparable to those obtained with natural estrogen. Therefore it appears that stilbestrol can replace the natural estrogens in all their therapeutic applications, and also it is a drug that is effective by mouth. It apparently has a true localized effect on the genitalia and has presumably the power to depress certain anterior pituitary functions, for example to suppress lactation. In three patients in whom uterine bleeding followed a course of stilbestrol, only scanty endometrium was obtained at biopsy. More and more evidence is being produced to show that uterine bleeding is primarily a local vascular phenomenon and is not necessarily directly related to the state of the endometrium. Thus, bleeding can occur from a preovulation or premenstrual or atrophic endometrium. When stilbestrol was given intramuscularly there were no toxic effects. When it was given orally nausea without vomiting was produced in three patients but in all these symptoms disappeared even when the use of the drug was continued.

Action of Drugs of Sulfanilamide Group.—McIntosh and Whitby studied the bodily defense mechanism and the action of sulfanilamide and its derivatives on bacteria. Their experiments support the view that sulfanilamide drugs have no stimulating action on leukocytes, phagocytes or the specific immune defenses of the body. Furthermore, since an in vitro effect can be demonstrated in serum or broth as well as in whole blood, it would not seem that leukocytes are a primary requirement. Concerning the action of the drugs on the micro-organisms, the authors explain (1) the capsular degeneration, (2) the failure of the drugs to check local multiplication and to prevent invasion of the body, (3) the time lag before the drugs become effective in vivo or in vitro and the tendency even to primary stimulation

of growth, (4) the quantitative relationship between the effective dose of the drug and the number of bacteria, (5) the fact that the drugs act best on young actively multiplying virulent organisms and (6) the variations in in vitro activity according to the medium in which the test is made. One explanation of the six points would be that in the sulfanilamide drugs substances have at last been found which exert a simple germicidal action in vivo as well as in vitro. Such an explanation would mean that the action is in striking contrast with that of the germicides phenol, acriflavine and brilliant green, which the authors have tested and found to show no evidence of a "lag" in action and certainly no tendency to exert an initial stimulation on the organism. The action appears to be much more subtle than that of a simple germicide. The failure of the drugs to check the initial local multiplication and invasion is obviously due to the "lag" in action, and the lag suggests a slow combination or neutralization by the drug operating on some essential food substance or enzyme. That combination or neutralization occurs is suggested by the quantitative relationship between drug and bacterium. A reasonable interpretation is that, in the case of streptococci, when either sulfanilamide or sulfapyridine is present, peptone broth supplies something to the organism which blood lacks, whereas in the case of pneumococci both blood and broth lack something essential to the organism. It is clear that, since peptone inhibits the action of both sulfanilamide and sulfapyridine on streptococci but not on pneumococci, the two organisms differ in the way in which the drug acts on them, and, although the modes of action may be the same in principle, there must be differences in detail. The most rational explanation of these experimental facts is that the sulfanilamide drugs in some way block the vital food supply of bacteria, the two drugs being equally effective in blocking the vital food for streptococci but sulfapyridine being decidedly more effective than sulfanilamide in blocking that for pneumococci. It is conceivable that the bacterial enzyme of which this food factor is the substrate should be inactivated. Rough and avirulent organisms, insusceptible to these drugs, do not have the exacting food requirements of virulent bacteria, and the failure of the sulfanilamide drugs to affect virus infections could be explained by the feeble enzymatic action which viruses are known to have. Therefore the mode of action of sulfanilamide and its derivatives is most probably bound up with the inactivation of bacterial enzymes, but the complete solution of the problem must depend on activities of the bacterial chemist.

Remissions in Schizophrenia.—Stalker and his colleagues compare the results obtained in the treatment of 218 cases of schizophrenia divided into three series according to whether treatment was by ordinary hospital methods, by hypoglycemia or with convulsant drugs. There was no significant difference in the numerical results obtained in schizophrenia by the three methods. Spontaneous remissions occurred most often in acute schizophrenic illnesses which could not be fitted into the standard subgroups, and in cases in which the affect is well preserved and there is little or no disharmony between mood and thought. Hypoglycemia gave the best results in the paranoid subgroup and in cases in which the affect is well preserved. There were no important complications. Convulsion therapy appeared to be best suited for stupor reactions. It was also useful in cases of psychoneurosis resistant to psychotherapy. The disadvantages of the treatment are that about half the patients object to it and that injuries can occur. Occasionally patients were made worse mentally. The field of special treatments is limited, but each should be used in the special type of case. They afford the best chance of recovery to a potentially recoverable patient whose illness is dragging on. They reduce the average duration of hospital treatment.

*Epituberculosis. W. B. Wood.—p. 205.
Effect of Tuberculous Infection on Carbonic Anhydrase of Rabbit's Blood. Cecilia Shiskin.—p. 227.

Epituberculosis.—Wood believes that epituberculosis is a manifestation of postprimary tuberculosis in childhood and occurs in a period characterized by enlargement of the bronchial glands and a tendency to exudation. The chief factor in its production is atelectasis due to bronchial blockage by tuberculous glands. A secondary factor is probably exudation into the alveoli and engorgement, the result of lymph stasis and vascular congestion. Tuberculous allergy possibly also plays a part for allergic reactions are common in the second stage. If gland caseation leads to rupture of the wall of a bronchus, a caseous bronchitis or bronchopneumonia may entirely alter the clinical picture and cause permanent damage to the lung. If the bronchial wall escapes such ulceration, restitution can occur and the collapsed lobe may return to its original condition. A failure to reexpand must in either event give rise to bronchiectasis, which is a common result of tuberculous adenitis. One cause of the hilus flare phenomenon is atelectasis of the right middle lobe due to bronchial compression. Collapse of the apical division of the lower lobe may cause a similar shadow and have a comparable origin. Many of the triangular shadows on the hilus are evidently due to a local atelectasis. Care is needed in their interpretation because other lesions of a tuberculous and nontuberculous nature may cause similar opacities. The term "epituberculosis," which has served its purpose and drawn attention to the condition, might now be abandoned.

Sexual Cycle and Blood Picture.—The studies reported in this paper by Kokubo were made on three healthy unmarried women. In one of them the cycles were of normal length (from twenty-eight to twenty-nine days), whereas in the other two they were quite irregular. The blood specimens were withdrawn from the ear lobe. The tests were repeated at weekly intervals for a period of three months. The results of the tests are listed in tables. The author differentiates four different periods in the cycle: the premenstrual, the menstrual, the postmenstrual and the interval period. Pointing out the common features of the blood pictures of the three healthy women, he says that the erythrocyte count decreased and fell to the minimum in the menstrual period. Hemoglobin decreased in the same period. The platelet count fluctuated regularly in a way characteristic of each person through one whole sexual cycle. Arneth's

nuclear shift of neutrophils was almost unaffected by the sexual cycles. Pathologic granules showed an inclination to decrease in the menstrual period and were within normal limits. Though hemosedimentation showed generally a normal value through the sexual cycles, there was an inclination for it to decrease one or two weeks after menstruation. Thus sexual cycles of women seem to cause a regular fluctuation of the blood picture, though subject to individual fluctuation, through the whole cycle.

*Early Regional Edema as Symptom of Lymphogranuloma Venereum. J. May.—p. 628.

Edema in Venereal Lymphogranuloma.—The regional edema of the abdominal wall, thigh and inguinal region, to which May gives his attention in this report, can be detected readily by palpation (preferably without rubber gloves). It is not accompanied by coloration of the skin, and it is soft, that is, it does not pit on pressure with the finger. Its extension varies greatly; often it is limited to the abdominal wall. If this is the case, detection may be difficult. The author recommends pinching of the skin or making small pleats at the level of the umbilicus along a line which corresponds to the entrance of the umbilical canal. Along this line the edema is most readily detected. When the edema invades the thigh, it is localized along the femoral line. In case of localization in the surroundings of the penoscroto-inguinal angle, the regional edema is always perceptible with the eye as well as by touch. The appearance of this early edema has no connection with the edema which may develop following incorrect interventions on the lymphatic mass. It originates in changes of the lymphatic vessels, which in turn are caused by the virus of venereal lymphogranuloma. The duration and evolution of the regional edema vary. At the author's clinic this symptom is searched for because it confirms the existence of the venereal lymphogranuloma which has been demonstrated by the reaction of Frei. However, the regional edema is of especial value in cases in which the venereal lymphogranuloma is associated with other venereal disorders such as gonorrhea, chancroid, fusospirillosis, ulcerating granuloma of the pudenda and syphilis. The infection with venereal lymphogranuloma and gonorrhea may be simultaneous or the gonorrhea may appear first. In the latter cases the venereal lymphogranuloma may develop at the end of the third or fourth week, when the gonorrheal urethritis has already been ameliorated by antigonococcic treatment. At this time the author observed the development of the regional edema. In cases in which the infection with venereal lymphogranuloma and gonorrhea is simultaneous the patient may present the symptoms of both disorders, but in some instances of simultaneous infection the venereal lymphogranuloma is detected only by the Frei reaction. The author further cites a case of chancroid in which the regional edema made him think of association with venereal lymphogranuloma, and the Frei reaction corroborated this suspicion. In a previously reported case of regional edema the Frei reaction proved positive and fusospirillosis was detected. Regarding the possible concurrence of venereal lymphogranuloma with ulcerating granuloma of the pudenda, the author says that as yet he is unable to decide this because the latter disorder is rare in Uruguay; nevertheless cases have been observed which suggest such a concurrence. Taking up the association of syphilis and venereal lymphogranuloma, he points out that Chevalier and Bernard have reported such observations and he shows that in the concurrence of these two venereal disorders the regional edema is an especially valuable symptom.

*External Pancreatic Secretion of Persons Having Undergone Gastrectomy. P. Santy, P. Mallet-Guy, M. Chambon and P. Folliet.—p. 9.
Spinofacial Anastomosis for Bilateral Traumatic Facial Paralysis: Late Results. H. Costantini and E. Curtillet.—p. 50.

External Pancreatic Secretion After Gastrectomy.—Santy and his associates point out that, in the course of regular control examinations of patients who had undergone gastrectomy for ulcer, they were surprised at the slowness and often the incompleteness with which the patients regained their weight. Diverse factors may be cited as possible explanations for this inadequate increase in weight. As regards the surgical technic, it is said that the majority of the patients had undergone an extensive gastrectomy. In some of the patients a faulty regimen can be held responsible for the fact that they failed to regain their normal weight, because for professional reasons many were unable to fractionate or multiply their meals, which is advisable for at least a certain number of months after the operation. However, there is a large number of cases in which neither of these factors can be held responsible for the persistent disturbance in assimilation. To throw more light on this problem the authors made studies on 128 patients in whom a gastrectomy had been performed more than six months and up to ten years previously. In a large number of these patients they verified roentgenologically the function of the gastric stump and of the gastrojejunal anastomosis, they determined the gastric acidity and finally, whenever it was possible, they studied the external pancreatic secretion. The latter factor is the one to which the authors give especial attention in this report. The methods employed in the study of the external pancreatic secretion were (1) gastrojejunal tubage, which permits the collection of the secretions of the duodenal papilla, (2) the stimulation of the pancreatic secretion by intrajejunal instillation of solutions of hydrochloric acid and (3) the measurement of the lipase activity of the pancreatic juice. The authors describe the results obtained with these tests in thirty-nine patients. Summarizing the results of the studies on the lipasic activity, they state that in fourteen of the patients the lipasic activity was within normal limits (35 to 55), eighteen had a weak lipasic activity (15 to 35), four had values between 10 and 15 and in the other three the results were practically nill. It was found that these values had no relation to the time that had elapsed since the operation, to the functional activity, to the gastric acidity or to the weight of the patient before and after the intervention. Thus the variations in the lipasic activity of the pancreatic juice do not seem to intervene directly and exclusively in the persistent emaciation of the patients having undergone gastrectomy. The authors think that factors like the rapidity of the gastric passage, the degree of anachlorhydria and the difficulties encountered by the patients in adhering to special modes of alimentation probably play a part in the emaciation that follows gastrectomy. But the disturbances in the humoral process regulating the pancreatic secretion plays doubtlessly a significant part. Attempting to explain the instability of the mechanism of eliciting the pancreatic secretion in gastrectomy patients, the authors say that it appears that an unknown factor disturbs the hormonal process which releases the secretion. The gastrectomy may introduce some perturbation in the conditions that are indispensable in the function of the pancreas. It is suggested that circulatory factors, particularly vasomotor mechanisms, which play a part in the pancreatic secretion, are damaged by gastrectomy.

*Indications for Adrenalectomy in Thrombo-Angiitis: Late Results in Three Cases. R. Leriche.—p. 377.
Conjoined Twins. P. Anokhine.—p. 379.

Adrenalectomy in Thrombo-Angiitis.—Leriche says that, instead of carefully studying the treatment of thrombo-angiitis in the different stages of its evolution, all sorts of theoretical arguments have been advanced to exclude adrenalectomy from the legitimate therapeutic attempts. He believes that this has been a mistake, for in his opinion adrenalectomy is the most efficacious of operations directed against arteritis in the cases in which it is indicated. In this paper he relates his experiences with adrenalectomy in carefully selected cases. One of his patients, a dentist, was adrenalectomized in March 1927 and was examined again more than eleven years after the operation. The detailed clinical history of this case indicates that adrenalectomy on the left side was done only after other therapeutic measures had failed. On the day after the operation the patient called attention to disappearance of the pains. The recovery from the operation was uneventful. About a year after the operation the patient stated that he was not troubled by claudication, that walking caused no pain and that he was able to work

eight hours a day. The patient was examined several times after this, the last time in May 1938, more than a year after the adrenalectomy. At that time the arterial status was still excellent. Another patient, for whom the author performed adrenalectomy in 1926, was examined again twelve years later and, as regards the arterial status, was completely cured. Information received from a third patient, who was subjected to adrenalectomy almost fourteen years before, revealed that he likewise had been free from complaints. In the last part of this report the author points out that in the course of twenty years he and his collaborators performed approximately 1,000 operations for various forms of arteritis. On the basis of the experiences he gained in the course of these years he discusses the indications for adrenalectomy, sympathectomy and arterioectomy.

Cardiac Disturbances in Diabetes Mellitus.—Hegglin investigated whether there are connections between diabetes mellitus and cardiac disturbances and what effects insulin exerts on the heart. His studies were made at the medical clinic of the University of Zurich. He found that the combination of diabetes mellitus and heart disease is comparatively frequent. The heart does not escape the general damage that is produced in the organism by the severe metabolic disturbance. To be sure, this applies chiefly to aged persons with diabetes. Whether heart disease and particularly coronary sclerosis develops also on the basis of juvenile diabetes, the author is unable to state. The administration of large doses of insulin to aged persons with diabetes results in impairment of the cardiac function. This does not imply that insulin is harmful also when given in small doses. Although in a few cases electrocardiographic changes were observed even after small doses, there never was a severe cardiac impairment, especially a cardiac infarct. In the cases in which cardiac infarct and diabetes concurred, no insulin treatment had preceded the development of the infarct. On the other hand, the large doses of insulin which are required for the treatment of diabetic coma may produce severe myocardial damage. For this reason aged persons with diabetes must be kept under close observation in order to avoid coma and its circulatory complications. By means of electrocardiographic studies it was possible to determine that a circulatory weakness during diabetic coma is chiefly due to a myocardial weakness, that is, it is not only of peripheral but also of cardiac origin. Consequently the therapy of the circulatory weakness must attempt to strengthen the heart by strophanthin and to counteract the peripheral insufficiency with the usual remedies. Moreover, it is important to avoid an additional myocardial impairment by insulin, the quantity of insulin should be just enough to counteract the acidotic disorder of the metabolism, but a hypoglycemia should be avoided.

*Atherosclerosis in Celiac Artery and Its Branches. E. Ferrari.—p. 424.

Atherosclerosis in Celiac Artery.—Ferrari discusses the pathogenic relations between vascular lesions of atherosclerosis and the local mechanical conditions of circulation. He made anatomic studies on the celiac artery and its branches (left gastric, hepatic and splenic) in fifty cases of atherosclerosis. He found that (1) the gastric artery is not involved by the disease and (2) the splenic artery is involved earlier and more acutely than the celiac and hepatic arteries. The main lesions are fibrosis of the media and degeneration up to atheroma of the intima. Intimal degeneration seems to be secondary to the medial lesions. Calcification of the media and tortuosity of the arteriosclerotic artery take place only in the splenic artery. Early in the development of the disease atherosclerosis involves only the peripheral segments of the splenic artery. Later on the condition progresses to the central segments of the splenic artery and to the celiac and hepatic arteries. In order of frequency the acuteness of the condition is first for the splenic then for the celiac and lastly for the hepatic artery. According to the author, the different behavior of the arteries for the development of the disease depends on anatomic and functional relations of the arteries with the given supplied territories. In pathologic conditions the increased resistance to circulation may result in the development of atherosclerosis if secondary factors, such as toxic, infectious, endocrine or constitutional, exist.

*Sulfanilamide in Venereal Lymphogranuloma. D. Peryassu.—p. 309.

Sulfanilamide in Venereal Lymphogranuloma.—Peryassu states that the classic treatments (physical, chemical or surgical) of venereal lymphogranuloma sometimes control the disease but not always. The author resorted to the administration of sulfanilamide in a group of patients, the number not being specified by the author. All had a positive Frei test and the disease was in an advanced stage. Four cases are reported in detail. He found that a complete sulfanilamide treatment induces recovery. Incomplete treatments are followed by recurrences. The author established the following types of treatment: (1) treatment by sulfanilamide alone, (2) sulfanilamide and roentgen treatments and (3) sulfanilamide and iodine or antimony treatments. In all three types the sulfanilamide treatment consists in administration of six daily tablets of the drug (rubiazol) up to a total of 180 tablets for each series. The entire treatment consists of two or three series with intervals of fifteen days of rest between the series, when no drugs of any kind were given. Treatment with sulfanilamide alone is indicated early in the development of venereal lymphogranuloma and before the appearance of fistula. The roentgen treatment consists in local roentgen irradiations, with the technic commonly used for ganglion roentgen therapy, in the course of the sulfanilamide treatment, the number of irradiations being decided by the evolution of the disease. It is indicated in advanced forms of venereal lymphogranuloma with the presence of many large fluctuating or nonfluctuating ganglions but no fistula. If fistulas exist the treatment consists in the administration of iodine or antimony preparations at regular intervals with the sulfanilamide treatment, namely during the fifteen days of rest between the sulfanilamide treatments. Sulfanilamide is well tolerated by the patients. In all cases the symptoms are relieved early in the course of the treatment. Reduction of the size of the ganglions up to complete disappearance and healing of the fistula take place as the treatment advances.

*Metastases of Carcinoma in Ovary with Especial Consideration of So-Called Krukenberg Tumors. W. Uhlmann.—p. 468.

Carcinoma Metastases in Ovary: Krukenberg Tumor.—Uhlmann says that opinions are still divided regarding the nature and pathogenesis of Krukenberg tumors of the ovaries. Krukenberg considered them as primary ovarian tumors which differed from other neoplasms of the ovary by their peculiar histologic structure. The most characteristic feature of the microscopic picture of these tumors is the "signet-ring" cells, in which the nucleus is placed far to the side, as a result of the mucous transformation of the protoplasm of the epithelial cells. These cells give a positive mucicarmine reaction. Moreover, there is a considerable proliferation of the ovarian connective tissue which simulates the aspects of a fibrosarcoma.

and, within this tissue, the signet-ring cells appear either isolated or in groups. Krukenberg's opinion that these tumors were of a primary nature was accepted by a number of investigators, but today many observers believe that Krukenberg's tumors represent metastases of primary tumors of the intestinal tract. In this paper Uhlmann presents a statistical review of fifty-two cases of ovarian carcinoma, which were examined at the pathologic institute of the University of Erlangen. In twenty-two of the cases the ovarian tumors were definitely of the Krukenberg type. In eleven other cases the tumors were probably also of this type, although the characteristic formation of mucus was absent. Among the twenty-two cases in which the ovarian tumors were definitely of the Krukenberg type there were fifteen in which the Krukenberg tumors represented metastases of a primary tumor in the gastrointestinal tract. However, a primary carcinoma of the gallbladder was detected in none of these cases. Of the remaining seven cases, only one can be designated as a primary tumor on the basis of postmortem studies. In the other six cases clarification was impossible, because no postmortem examination was made. In six cases the appearance of the Krukenberg tumors was preceded by gastric resection on account of carcinoma of the stomach. In five instances the primary tumor was detected at the time of operation. The average age of all women with ovarian carcinoma was 46.7 years, that of those with Krukenberg tumors 45.2 years. Most of the women were of the age group between 41 and 50, but there were also some between the ages of 21 and 30. Signs of masculation were observed in only one of the women with Krukenberg tumors. In the last part of his report the author relates a case that he observed recently. This case is noteworthy because the tumor seems to be of a primary nature. Thus, of a total number of twenty-three cases of Krukenberg tumor, two may be regarded as having developed in the ovary as primary tumors, a possibility that is doubted by some investigators.

Symptomatic Sprue in Gastrocolic Fistula. W. Mohr.—p. 287.
Hypophysis and Carcinoma. Wilhelmine Rodewald.—p. 290.

Medical Problems in Substratosphere. — Strughold describes the effect of altitude during an ascent to 8,000 or 9,000 meters. He bases his report on the observations he made on his collaborators, with the aid of reflex physiology, pointing out that the tendon reflexes, for instance the patellar reflex, are an excellent indicator of the physiologic changes in the organism which take place under the influence of the high altitude. By constantly recording the reflexes during an ascent, it is found that up to an altitude of 2,500 meters the reflexes remain unchanged. After that they become weakened, but at an altitude of 5,000 meters their reduction changes into an intensification. This hyperreflexia increases wavelike with higher altitudes and finally leads to the so-called altitude convulsions. The hyporeflexia is a compensatory reaction to the beginning oxygen deficiency, for it sets in simultaneously with the compensatory mechanisms of the circulation and of the respiration. Its onset signifies the "reaction threshold." The intensification of the reflexes indicates that the compensatory measures become insufficient and that now a real oxygen hunger exists. Thus the onset of the intensification of the reflexes may be designated as the "disturbance threshold." When the convulsions begin, even the central regulation of the reflexes is impaired and this stage of the high altitude action is designated as the "critical threshold," because at this point life is threatened and oxygen must be given at once. By the administration of oxygen the convulsions can be overcome. In experiments on animals it has been demonstrated that there is a further stage in high altitude action, the so-called lethal threshold, where the convulsions change into paralysis. The author admits that in practice the problem of high altitude flying seems to have been solved by supplying oxygen when certain altitudes have been reached. However, under certain conditions it may become necessary for the pilot to separate himself from the oxygen apparatus and in this connection the question of the "time reserve" arises, that is, the length of time that elapses between the cessation of oxygen respiration and the "disturbance threshold." Studies on this "time reserve" revealed to the author that at altitudes of 8,000 or 9,000 meters this reserve of time extends over only a few minutes if the person is at rest; it is reduced to one half if the person is exerting energy in work. In many instances, however, the time reserve must be estimated in seconds rather than in minutes and the author thinks that in such emergencies the pilot should at once descend from the substratospheric altitudes toward the physiologic atmosphere, that is to 3,000 or 4,000 meters.

Treatment of Varicose Syndrome. J. Wirth.—p. 312.
Gonorrhea in Man in Light of New Chemotherapy. A. Glingar.—p. 315.

Congenital Clubfoot.—Following brief remarks about the etiology and the various forms of congenital clubfoot, Gaugele gives his attention to the therapy. He first outlines the treatment that was in use from about the beginning of the century to the middle twenties. It generally consisted in exercise and massage during the first six months and after that in redressement often with plaster of paris casts; later orthopedic appliances and orthopedic shoes were employed. This treatment often extended over many years and the results were not always satisfactory. More recently, demands were heard for an early treatment. The method of early treatment with which the author obtained favorable results for the last ten years was first employed by Spitzy. The author begins the treatment on the seventh or eighth day, at the latest on the fourteenth day after birth. It consists in applying strips of adhesive tape that are from 6 to 8 cm. wide. In case of the right foot, the bandage is begun on the external edge of the dorsum of the foot, goes toward the internal edge, over the sole toward the outer edge, then upward toward the thigh (the leg being bent in the knee), around the thigh and ends at the internal side of the leg. An illustration clarifies the application of the bandage. The correct adjustment of this bandage requires a certain amount of practice. During the first eight days the foot must be inspected frequently by a nurse and at least twice a day by the physician. At least during the first three weeks of treatment the infant must remain in the hospital; after that the treatment may be ambulatory. The results are excellent. After from six to eight weeks of treatment the foot is usually normal. After that the child wears braces during the greatest part of the day and night, but during the day they are occasionally removed and exercises are made by the mother. In difficult cases the wearing of braces may have to be alternated with the application of adhesive bandages. The author deplores that not all cases of congenital clubfoot are subjected to this early treatment and that consequently interventions may be necessary on older children and even on adults. He recommends an operation which combines tendon transplantation with wedge osteotomy from the lateral part of the foot.

*Hematologic Diagnosis of Hodgkin's Disease. F. Velasco Montes.—p. 255.
Secondary Necrosis of Head of Femur Following Traumatic Dislocation of Hip Joint in Boy Aged 14. H.-H. Mutschler.—p. 258.

Hematologic Diagnosis of Hodgkin's Disease.—Velasco Montes points out that, in view of the clinical polymorphism of Hodgkin's disease, its diagnosis often requires special examinations. The blood picture is extremely multiform not only as regards the different cases but also in the same patient. Numerous investigators attempt to diagnose Hodgkin's disease by means of sternal puncture, but this involves considerable difficulties. Moreover, it has been found that the bone marrow is involved in only about half of the cases of Hodgkin's disease.

At any rate the author thinks that sternal puncture will never assume the significance of the adenopuncture in the diagnosis of Hodgkin's disease. He regards the glandular puncture as the method of choice and he employs it regularly in doubtful cases. The diseased glands are usually characterized by cellular polymorphism or by the presence of a large number of cells of an endothelioid nature, which seem to be related to, or perhaps are preliminary stages of, Sternberg's cells. On the basis of the predominance of certain types of cells in the adenograms, for instance, of neutrophils, eosinophils or reticular cells, classifications have been attempted. However, the author thinks that such classifications are arbitrary and that the various types are merely variants of the fundamental polymorphism. To be sure, a certain amount of experience is necessary to recognize among the large number of cells those which are decisive for the diagnosis, and the author suggests that this is probably the reason why this valuable method of examination is used so little by others than experienced hematologists. An additional advantage of adenopuncture is that patients never object to it as they do to exploratory excision. Moreover, the glandular puncture can be repeated whenever it seems necessary, for instance, to evaluate the efficacy of a treatment; it does not involve the danger of a flare-up or of reactivation of the disease, as is sometimes the case in exploratory excision. After the glands have been treated with roentgen rays, the interpretation of their cellular aspects is extremely difficult. This applies to the adenogram as well as to the exploratory excision. To be sure, there are also cases in which even in the absence of roentgen irradiation the diagnosis cannot be made on the basis of glandular examination. Cases have been described in which only splenic puncture made the diagnosis possible. Occasionally, access to the diseased glands is difficult or their severe sclerosis makes an adenopuncture impossible. Moreover, purely splenic forms of Hodgkin's disease have been observed. The splenogram of Hodgkin's disease discloses Sternberg's cells.

Connective Tissue Structure and Elasticity. H. Homma.—p. 139.
*Differential Diagnostic Difficulties in Pulmonary Actinomycosis. W. Breu and H. Seyfried.—p. 142.

Differential Diagnostic Difficulties in Actinomycosis.—According to Breu and Seyfried the diagnosis of pulmonary actinomycosis is usually made late. Whereas other pulmonary disorders are characterized by signs that can be detected by percussion, auscultation and roentgenography, these methods of examination fail in cases of actinomycosis. The aspects of actinomycosis of the lung differ greatly. Moreover, the histologic and bacteriologic examinations and the animal experiments fail occasionally so that their negative outcome does not definitely exclude actinomycosis. Even if Actinomyces is detected at the site of the disease process, this is not necessarily a proof of an actinomycosis; this was emphasized by Wassmund in actinomycosis of the jaw. The authors describe a case in which the diagnosis proved extremely difficult and was finally decided in the course of the necropsy. The patient presented some aspects of diabetic coma; cerebral symptoms suggested a brain tumor, and these cerebral symptoms together with a shrinking process in the right lung finally led to the diagnosis of bronchiectasis with metastatic cerebral abscesses. This diagnosis was at first corroborated by the necropsy, but several days later the microscopic examination disclosed Actinomyces in the walls of the bronchiectasis and in the pus of the cerebral pus. When this was discovered, some characteristics of pulmonary actinomycosis became evident in the clinical aspects. The described case as well as other reports exhibit severe shrinkage of the thorax and the pleura, distortion of the heart and discrepancies between the severe changes and the apparently benign character of the process. The localization of the process in the right upper lobe also could have been utilized in the differential diagnosis. Metastases in the brain likewise are no exception in actinomycosis, for twenty-one such cases have been collected from the literature. The coarse rales over the lungs seem significant, because the authors observed this symptom in all of their cases of pulmonary actinomycosis. Following the review of three other cases, the authors discuss the treatment. They think that besides the various forms of serotherapy (convalescent serum, vaccines and so on) the combination of iodine and roentgen therapy is most common and most effective.

Zeitschrift für urologische Chirurgie, Berlin

Elimination Urography in Light of Gynecology. G. Kulitzy and J. Molnár.—p. 476.
New Surgical Method for Cure of Phimosis. K. Haszler.—p. 490.

Hepatic Function in Uremia.—Babics shows that true uremia is not a primary disorder but a syndrome resulting from intoxication of the organism and that consequently its treatment is similar to that of intoxications. Three types of treatment are possible: one restricts the foods, the final products of which exert toxic action; a second method aims at the prompt removal of the toxic substances from the organism, and the third method aims at the detoxication of the poisonous substances by chemical decomposition or neutralization. The condition of the kidney plays an important part in the prognosis of uremia. Moreover, the prognosis must take into consideration that a surgical intervention, even one outside the renal apparatus, taxes the whole organism and especially the liver. It was determined at the author's clinic that during the severe stages of uremia not only the kidney is impaired but also the hepatic function. This was demonstrated by means of the bengal rose test of Fiessinger and Walter. This test of the hepatic function has the advantage that it is entirely independent of renal activity. Since it had been observed on patients with hepatic disorders that the subcutaneous or intramuscular injection of a lipase preparation produced great improvement, it was decided to administer the lipase preparation also in patients with uremia. The author reports the clinical histories of several patients in whom these injections exerted a beneficial effect. Summarizing his observations he says that the liver plays an important part in the pathogenesis of uremia. Some cases of uremia can be successfully counteracted by improving the hepatic function; this is especially possible in those cases in which the xanthoprotein reaction indicates that the products of decomposition that are toxic for the liver have not yet reached extremely high values. If it is considered that a large group of urologic disorders, hypertrophy of the prostate, for instance, concerns aged persons, in whom defective hepatic function is as such quite frequent, it seems advisable to stimulate the hepatic function even in the absence of signs of uremia, whenever it is likely that an instrumental or surgical intervention will place an added burden on the organism and especially the renal activity. The author stresses that the lipase preparation which he used for the stimulation of the hepatic activity produced no undesirable effects.

Intestinal Tuberculosis.—Systematic x-ray examination together with consideration of the complaints of the patients and the blood picture make possible, according to Tsigelnik, early diagnosis of intestinal tuberculosis. This complication may develop as early as one year after the onset of symptoms of pulmonary tuberculosis. While the usual mode of infection is the swallowing of the tubercle bacilli, the hematogenous mode of infection may occur. In the author's material it

amounted to 9.3 per cent. Symptoms may be entirely absent, as was the case in six of fifty cases later examined post mortem by the author. The incidence of intestinal tuberculosis is more to be expected in cases of a disseminated process in the lungs with cavitation and bacilli in the sputum. Suggestive symptoms are pain and tenderness, particularly when in the ileocecal region, nausea, loss of appetite, vomiting and constipation alternating with diarrhea. Occult blood in the feces was found in 18 per cent of the cases. The author stresses the importance of roentgenologic study with the aid of a contrast meal administered by mouth and by rectum. In his material of 150 cases it was positive in 80 per cent. Characteristic observations are the presence of horizontal levels in the small intestine, due to the loss of tone of the large intestine which results from the action of tuberculous toxins on the neuromuscular elements of the latter, and spastic states of the cecum and the ascending colon. Next to roentgenologic observations, the author stresses the development of hypochromic anemia. The hypochromia is the result of toxemia rather than of occult bleeding. Of 150 patients 120 had a hemoglobin below 60 per cent, while only twenty-seven had blood in the feces. The author feels that intestinal tuberculosis is not necessarily a hopeless condition. He sees in vitamin C an important addition to the dietetic treatment and is enthusiastic about the pneumoperitoneum therapy. Of fifty patients subjected to this treatment thirty-two obtained a remission which lasted twelve months. The results, he believes, are due to the antispastic effect of gas on the neuromuscular elements of the diseased intestine. The prophylaxis of intestinal tuberculosis consists in the correction of habitual constipation in cases of pulmonary tuberculosis, of instructing patients not to swallow their sputum, of collapse therapy in order to render their sputum bacillus free, and the roentgenologic study of the intestinal tract in cases of pulmonary tuberculosis.

Demyanovich's Therapy of Scabies.—According to Levitan, Demyanovich in 1933 proposed the following rapid method of treating scabies: The patient rubs a 40 per cent solution of thiosulfate into his skin for fifteen minutes. Ten minutes later the skin is covered with salt crystals in order to dry it. This is followed by another period of a fifteen minute rub with a 5 per cent solution of hydrochloric acid. The chemical reaction resulting between the hydrochloric acid and the thiosulfate releases a number of acaricidic substances such as sulfurous acid, sulfur dioxide and sulfur, which in their nascent state are fatal to the itch mite. This reaction is accompanied by the freeing of sulfurous gas characterized by an unpleasant odor and irritating effect on the upper respiratory passages of the patients and the attending personnel. The procedure is repeated fifteen minutes later, the complete treatment occupying about one hour and forty-five minutes. On the basis of 10,017 cases of scabies in which this method of treatment was used at the dermatologic clinic of the Leningrad Pediatric Institute, the author concludes that, while the treatment is simple, clean and economical, it does not cure all of the patients in one treatment. In his material this was accomplished in 4,189 cases (41.2 per cent). Longstanding cases and those complicated with various dermatoses required from two to five treatments at intervals of from six to seven days. The modification of the method consisted of a preliminary shower bath with green soap and brush, and disinfection of the patients' clothes. The modification resulted in doubling the number of cures after one treatment in the next 4,000 patients.

Acute Anterior Poliomyelitis.—Broekema surveys more than seventy cases of poliomyelitis which were treated at the children's clinic of the university of Leyden in the course of the epidemic of 1938. Convulsions developed in only two of the seventy cases. The dromedary type of fever curve was observed in 10 per cent of the cases. Four of the patients had had certain contact with other patients who had poliomyelitis. Two children were admitted on the basis of a family history of poliomyelitis, that is, a brother or sister had poliomyelitis; both of these patients had a nonparalytic form of poliomyelitis. The fact that a large number of patients had family members at home ill with disorders resembling poliomyelitis suggests a large number of abortive cases. Of the seventy hospitalized patients, thirteen remained free from paralytic symptoms. Of the fifty-seven with paralysis, nine succumbed several hours or days after hospitalization. All except one of the children, who died, were 3 years or less of age and in all of them the respiratory apparatus was involved. The therapeutic methods employed were convalescent serum, the antipoliomyelitis serum of Pettit, blood transfusion, methenamine and intralumbar injection of vitamin B_1. A table, which lists eighteen cases that were treated with vitamin B_1 and fourteen that were treated without this vitamin, indicates that in the first group the therapeutic results were better than in the second group.

Vitamin C and Tuberculin Reaction.—Birkhaug reports the effect of ascorbic acid on the intracutaneous tuberculin reaction in tuberculous guinea pigs. Following the subcutaneous inoculation with approximately 538 viable bovine tubercle bacilli, twenty-four guinea pigs were maintained on a normal diet, while half of the group received in addition 10 mg. of ascorbic acid by mouth daily until all the animals were killed sixty-four days after inoculation. The daily titration of the vitamin C excreted in the urine informed the author that the animals treated with ascorbic acid were continuously kept in a state of hypervitaminosis C and that the controls developed a progressive hypovitaminosis C. Subsequent postmortem titration of the vitamin C content of the adrenals confirmed the direct correlation with the urinary content. The author describes the outcome of the tuberculin reactions on the twenty-fourth, fifty-first and sixty-second day after inoculation. He reaches the conclusion that the daily oral administration of crystalline vitamin C significantly inhibits the tuberculin reaction in tuberculous guinea pigs. The degree of inhibition of the tuberculin reaction is definitely correlated with the urinary excretion and adrenal content of vitamin C in the tuberculous animal.

Tuberculosis in Animals Treated with Ascorbic Acid.—Birkhaug discusses the tuberculous lesions that were observed in tuberculous animals that were treated with ascorbic acid and in the controls that did not receive ascorbic acid. He found that C hypervitaminosis, induced by the daily oral administration of 10 mg. of l-ascorbic acid, caused a significant increase in body weight and reduction in the tuberculous lesions of guinea pigs injected subcutaneously with approximately 500 viable bovine tubercle bacilli and killed sixty-four days after inoculation. Microscopic examination revealed less caseonecrotic lesions, more collagenous tissue within and around the tuberculous centers and less dispersion of tubercle bacilli in animals with C hypervitaminosis than was observed in the controls.

THE SURGICAL RISK IN PATIENTS WITH CORONARY DISEASE

HAROLD J. BRUMM, M.D.
Fellow in Medicine, the Mayo Foundation
AND
FREDRICK A. WILLIUS, M.D.
ROCHESTER, MINN.

The association of coronary disease and surgical conditions presents a problem of great magnitude to both the clinician and the surgeon. It is generally conceded that the patient with coronary disease faces operative procedures with hazards considerably greater than the comparable patient with a normal heart. In fact, the premise may be stated that even the individual with coronary disease who is not confronted with the necessity of surgical intervention constantly lives under the hazards of his disease, and the reality of these hazards becomes evident when one recalls to mind the frequent occurrence of sudden death of such patients.

There are, however, numerous instances when patients with coronary disease harbor coexisting diseases which demand surgical procedures and in which life cannot be extended without operation. Notable examples are malignant diseases in which clinical evidence supports the fact that there is a reasonable chance of cure by operation and certain acute inflammatory diseases, such as appendicitis, suppurative or gangrenous cholecystitis, perforating lesions of the viscera, and strangulated hernia. Likewise in certain cases of cholelithiasis, especially those in which severe attacks of colic occur or in which chronic dyspepsia interferes with proper nutrition, obstruction of the common bile duct, obstructing renal calculi, obstructing enlargement of the prostate gland, ovarian cyst with torsion of the pedicle, intestinal obstruction and hyperthyroidism, operative procedures are undertaken with complete justification. Other conditions than those mentioned may at times indicate surgical intervention.

To a considerable degree, the results of surgical intervention under these unfavorable conditions are dependent on the expertness and finesse exercised in the management of the patient by all concerned. This includes not only the surgeon but likewise the anesthetist and the clinician. The time element is of extreme importance, for the shorter the time of operation and anesthesia, the less marked is the added load imposed on the cardiovascular system. Likewise, gentleness in the manipulation of organs and tissues lessens the dangers of surgical shock, which in itself may tilt the balance away from recovery in these patients. Of paramount importance is the surgeon's determination to limit the operation to the procedure planned in advance and to avoid undertaking additional operative steps that might be indicated in the patient without heart disease. Needless to say, surgical procedures not of urgent importance have no place in this discussion and are to be condemned as unwise and extremely hazardous.

In the appraisal of the case of coronary disease in which surgical intervention is contemplated, the physician must not be unaware of the role that postoperative complications may play in the final outcome. Such complications as pneumonia, peritonitis and parotitis, which in themselves may not necessarily prove fatal, may occur with sufficient severity to be responsible for failure of the heart.

This study was undertaken to derive definite quantitative values regarding the cardiac mortality under the circumstances mentioned. Our material comprises 257 cases of severe coronary disease, representing coronary atherosclerosis with the anginal syndrome and cases presenting healed cardiac infarcts with or without recurrent angina. Minor operative procedures are not included.

As one would anticipate, the majority of the patients were found to be grouped in the later years of life. One hundred and forty-eight patients (57.6 per cent) were 60 years of age or older. The youngest patient was 35, the oldest 83 and the average age of the entire group was 60.3 years. There were 186 men and seventy-one women, a ratio of 2.6:1. The predominance of men corresponds to the increased prevalence of coronary disease in that sex.

Approximately half (50.4 per cent) of the cases exhibited electrocardiograms revealing important abnormalities, which included significant T wave negativity, incomplete and complete bundle branch block, complete heart block and auricular fibrillation. Previous coronary thrombosis with healed cardiac infarction had occurred in thirty-two cases (12.4 per cent). Well marked hypertension was noted in 100 cases (38.9 per cent).

On the premise already established that the cases under discussion were examples of perfectly justified surgical intervention, a presentation of the operative procedures included in this study is of importance.

OPERATIONS

Operations on the Gallbladder and Biliary Passages.—There were forty-seven patients in this group, and in each instance a surgical procedure was deemed absolutely necessary in order to prolong the patient's life.

From the Section on Cardiology, the Mayo Clinic.

There were twenty-seven men and twenty women. The youngest patient was 40 and the oldest 75, while the average age of the group was 53.6 years.

In the appraisal of these patients as well as those in the subsequent groups it is important to bear in mind the fact that they are largely in the later periods of life. It is well recognized that even though no associated serious disease exists they comprise a group wherein the risk of surgical operation tends to be greater than for identical procedures in younger patients.

Cholecystectomy was performed in forty-three cases, eight of them requiring additional procedures. In three cases choledocholithotomy was necessary and in four appendectomy was performed. Two cardiac deaths occurred while the patients were still in the hospital, both resulting from congestive heart failure. They represented marked examples of obliterative coronary atherosclerosis with the anginal syndrome in cases in which severe recurrent biliary colics associated with cholelithiasis made surgical intervention imperative. The myocardium of both patients showed marked myofibrosis.

Among the remaining patients were two on whom cholecystostomy was performed, one on whom choledocholithotomy was carried out for obstructive jaundice and whose gallbladder had been removed previously elsewhere and one on whom a palliative cholecystogastrostomy was made because of carcinoma of the head of the pancreas. There were no cardiac deaths among these patients.

TABLE 1.—*The Cardiac Mortality in 257 Cases of Surgical Operation on Patients with Severe Coronary Disease* *

		Males	Females				Number	Per Cent
257	60.3	186	71	3.1	32	100	11	4.3

* The surgical procedures are detailed in the text.

Operations on the Stomach and Duodenum.—This group comprised eighteen patients on whom operation was performed because of the presence of gastric and duodenal lesions. There were fifteen men and three women. The youngest patient was 44, the oldest was 73 and the average age for the group was 61.

Partial gastrectomy was performed in eleven cases, and one cardiac death occurred, of a man aged 60 with a chronic perforating ulcer of the duodenum with partial obstruction, in whom coronary thrombosis developed with acute cardiac infarction three days after operation. He had suffered from the anginal syndrome for ten years and the risk of operation was well appreciated by the patient and all concerned in his management. The coronary arteries were markedly atherosclerotic with partial obliteration of their lumens.

In five cases posterior gastro-enterostomy was done, in one case an anterior gastro-enterostomy and enteroanastomosis, and in one case a gastroduodenostomy. No cardiac deaths occurred among these patients.

Operations on the Intestine and Rectum.—There were only thirteen patients in this group. Nine were men and four were women. The youngest patient was 50, the oldest was 73, and the average age for the group was 62. In six cases resection of portions of the colon or rectum was carried out for carcinoma. Colostomy was performed in two cases, ileocolostomy in three, fistulectomy in one and fulguration of a carcinoma of the rectum in one.

One cardiac death occurred, of a man aged 62 who underwent a posterior resection of the rectum for carcinoma. He died suddenly three days after operation, but no thrombosis of the coronary arteries was demonstrated at postmortem examination and no other cause for sudden death was demonstrated. The anginal syndrome had been present for four years.

Urologic Operations Excluding Transurethral Prostatic Resection.—This group comprised a miscellaneous assortment of surgical operations. There were twenty-six patients, of whom twenty-three were men and three were women. The youngest patient was 40, the oldest was 78 and the average age was 61.8 years.

The operations performed included nephrectomy in two cases, nephrostomy in one, suprapubic cystostomy in six, pelviolithotomy in four, resection of the urinary bladder in two, suprapubic prostatectomy in six, transurethral removal of bladder tumor in four and orchidectomy in one.

One death resulted from cardiac causes, which occurred in a man aged 70 on whom suprapubic cystostomy was performed. He died three days after operation from coronary thrombosis, and postmortem examination verified the clinical diagnosis of an acute infarct of the left ventricle. The anginal syndrome had occurred over a period of two years.

Transurethral Prostatic Resection.—There were sixty-three patients recorded in this group. The youngest patient was 55, the oldest was 83 and the average age of the group was 67.8 years. No cardiac deaths occurred among these patients.

Operations on the Breast.—Ten patients comprised this group. The sex incidence was equal. This unusual approximation of sex incidence was occasioned by the fact that five elderly men presented tumors of the breast which clinically suggested the possibility of carcinoma. Again, the predominance of coronary disease among men tends to upset the normal sex incidence of tumors of the breast. The youngest patient was 50, the oldest was 73 and the average age 65 years. In four cases radical amputation of a breast was performed, while in six cases simple amputation of a breast was carried out. No cardiac deaths occurred.

Gynecologic Operations.—There were twelve patients recorded in this group. The youngest patient was 35, the oldest was 66 and the average age of the patients 52.7 years. The 35 year old patient had marked hypertension and the anginal syndrome had been present for ten months.

The operations performed were total abdominal hysterectomy in six cases, subtotal abdominal hysterectomy in one, vaginectomy in one, vulvectomy in two and an interposition operation and perineorrhaphy for marked uterine prolapse in two. There were no cardiac deaths.

Thyroidectomy.—Thyroidectomy was performed in forty-two cases for either exophthalmic goiter, hyperfunctioning adenomatous goiter or substernal adenomatous goiter without hyperthyroidism. There were twenty-three men and nineteen women. The youngest patient was 46, the oldest was 76 and the average age

for the group was 58.7 years. Three patients died from cardiac causes and in all three death resulted from coronary thrombosis.

It has long been a recognized fact that patients with coronary atherosclerosis, especially those with the anginal syndrome, respond badly to the presence of hyperthyroidism. The expectation of life in cases not coming to operation is extremely short.

Miscellaneous Abdominal Operations.—There was a small group of eight patients on whom various abdominal operations were performed which could not be recorded in the previous classification. There were seven men and one woman. The range of age varied from 49 to 74, the average being 59.

The operations included appendectomy in four cases, repair of diaphragmatic hernia in one, exploration of abdominal carcinomatosis in two and exploration for abdominal sinus in one. One cardiac death occurred, of a man aged 52 in whom repair of a diaphragmatic hernia was performed. He had suffered from the anginal syndrome for five years and died two days after operation from coronary thrombosis.

Miscellaneous Operations.—This group of eighteen cases represented a miscellaneous assortment of surgical procedures. There were fourteen men and four women. The youngest patient was 37, the oldest 72 and the average age for the group was 54.5 years.

The operations were amputation of a leg in two cases, sympathetic nerve resections in five, tracheotomy and diathermy of the vocal cord for epithelioma in two, laryngectomy in one, diathermy and removal of a carcinoma of the tongue in one, removal of a pituitary tumor in one, radical mastoidectomy in one, excision of a parotid tumor in two, herniorrhaphy in two and a two stage excision of a pharyngo-esophageal diverticulum in one.

Two cardiac deaths occurred, both in patients with severe recurrent angina pectoris in whom relief was sought through the interruption of nerve paths. In the one case posterior nerve resection was carried out and in the other bilateral cervicothoracic nerve section. The first patient died the day of operation from coronary thrombosis and the other died suddenly the same day without thrombotic occlusion.

COMMENT

In order to avoid misunderstanding regarding the type of case chosen for this study we wish to state clearly that the only basis for inclusion was the severity of the coronary disease as determined by its clinical expression. Many instances of less severe coronary atherosclerosis were excluded as not representing surgical hazards of significance and therefore would only be misleading in the final analysis. It must, however, be remembered that not all patients with severe coronary disease associated with surgical conditions observed at the Mayo Clinic were subjected to operation, although in extreme emergencies some were accepted. Such cases comprise recent coronary thrombosis, status anginosus, congestive heart failure, Stokes-Adams seizures and episodes of nocturnal dyspnea or "cardiac asthma."

In this investigation only eleven (4.3 per cent) cardiac deaths occurred (table 1). A careful review of these cases is important, and the facts derived from this analysis are recorded in table 2.

It is desirable at this point to amplify the discussion regarding the surgical indications in these fatal cases. In case 1 the symptoms resulting from a diaphragmatic hernia fully justified the anticipated risk of repair. In case 2, in which partial gastrectomy and duodenostomy were performed for multiple hemorrhagic duodenal ulcers with obstruction, the patient had such a marked degree of incapacity and discomfort that he insisted on accepting the hazards of surgical intervention. In case 3, in which carcinoma of the urinary bladder existed, the only reasonable chance for cure was in operation. In cases 4, 5 and 6 thyroidectomy seemed clearly indicated, owing to either hyperthyroidism or

11	37	♂	Bilateral cervicothoracic ganglionectomy with resection of their trunks	Regional and nitrous oxide	3.5	T wave negativity lead 1	Sudden death	0	Coronary sclerosis (3) with extensive healed infarct of the left ventricle

substernal adenomatous goiter with obstruction. In cases 7 and 8 severe recurrent biliary colics resulting from cholelithiasis and chronic cholecystitis clearly justified operation. In case 9 the presence of carcinoma of the sigmoid predicted either death from carcinoma or possible cure from resection. Cases 10 and 11 represented intractable cases of the anginal syndrome, coming under observation during those years when resection of nerve structure seemed to be a justifiable procedure for that disease.

Seven deaths were attributable to coronary thrombosis with acute cardiac infarction, two were attributable to congestive heart failure and two occurred abruptly and apparently without thrombotic occlusion. It is interesting and important to note that the average age of the patients dying from cardiac causes was 60.7 years (excluding the patient aged 37, this relatively young man being an exception).

In a recent study, Master, Dack and Jaffe[1] approached the problem from a somewhat different angle, determining only the incidence of postoperative coronary occlusion. Among 625 seizures of occlusion of the coronary artery, thirty-five (5.6 per cent) occurred following operation in the hospital. In analyzing the operative procedures in their cases one finds nine which in magnitude are not comparable to those in this study. They likewise emphasize the observation that the majority of the patients were in the later years of life.

We believe that the cardiac mortality in the group of cases presented in this study is remarkably low and should encourage the sufferers from coronary disease when surgical intervention is necessary. However, it must not instil false optimism into the clinician or the surgeon, for they must realize that this accomplishment is not of casual origin but one resulting from the coordination of careful preoperative study and judicious selection, expert administration of anesthetic agents and skilful surgical technic and judgment. Operation must be confined to those cases presenting unmistakable indications and the procedure limited to the primary condition. Surgical procedures that are not urgent have no place in the cases under discussion.

SUMMARY

Two hundred and fifty-seven patients with severe coronary disease undergoing necessary surgical operation form the basis for this study. The average age of the patients was 60.3 years. The anginal syndrome had existed for an average of 3.1 years. Thirty-two patients had healed cardiac infarcts at the time of operation. Well marked hypertension occurred in 100 cases. Eleven patients (4.3 per cent) died from cardiac causes. Death resulted from coronary thrombosis in seven, from congestive heart failure in two and abruptly without apparent thrombotic occlusion in two.

A Great Revival.—The future of medicine lies with the younger and recently qualified generation and with their successors. *It is within their power to bring Clinical Science in* this country to a great revival.—Lewis, Sir Thomas: Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

THE IMMEDIATE AND ULTIMATE PROGNOSIS IN HEART DISEASE

WITH ESPECIAL REFERENCE TO "PERMANENT TOTAL DISABILITY"

PAUL D. WHITE, M.D.

BOSTON

The growth of fundamental concepts in the medical world is very slow despite the many advances constantly made into unexplored regions. Often a generation or more of time elapses after a discovery before there dawns its full significance. The adequate correlation of certain discoveries, old or new, is often the most fundamental of all. It is of such a basic concept in its infancy that I would treat herewith.

Before 1500 A. D. heart disease as such was actually unknown. Rare individual cases may have been suspected or even recognized but they were not written down. The general point of view was that if the heart should be injured in any important way death would come at once. Heart cases were being called something else—lung disease, dropsy, abnormalities of the humors, and so on. Then came the autopsy experience of the sixteenth, seventeenth and eighteenth centuries which revealed the common occurrence of heart diseases of all kinds, the etiology of which has been more and more the focus of attention during the last hundred years.

The damaged heart, quite fully recognized nowadays both at autopsy and during life, has been looming up as the great ogre in public and in private health. It is heralded far and wide as the greatest cause of death, outstripping all its competitors, such as tuberculosis, pneumonia and cancer. An uncritical, one-sided publicity has sprouted tens of thousands of cardiac neuroses in otherwise healthy persons and ruined the morale and crippled the lives of thousands of persons with heart trouble but with no reason to be "cardiac cripples." It is to help to establish a campaign against certain misconceptions that I welcome this opportunity.

Slowly in the last generation or two appreciation has come to the minds of certain discerning physicians like Rosenbach in 1878 and Mackenzie at the turn of the century that the functional state of the circulation and the cardiac reserve are at least as important as the structural changes or lesions in the appraisal of the prognosis and in the management of persons with heart symptoms and signs. That many persons with heart disease may live long and active lives has gradually become well recognized. In fact, the need of recruiting the British army in the World War forced the wise disregard of relatively unimportant heart murmurs and swung the pendulum too far for a while from the one time oversolicitude concerning cardiac signs to the neglect of such signs in ultimate prognosis.

The conception that despite heart disease life may last long and activity be but little hampered has been well established in the clinical medicine of today when we have to deal with chronic valvular disease and with moderate cardiac enlargement, but there has not yet been adequate recognition of the distinction between

Read before the International Medical Assembly of the Interstate Postgraduate Medical Association of North America, Philadelphia, Nov. 1, 1938.

UNIVERSITY OF WASHINGTON
SCHOOL OF NURSING
HARBORVIEW DIVISION

immediate and ultimate prognosis in heart disease, between the dangers of acute processes which may seriously jeopardize life or activity and the common possibility of their complete or almost complete subsidence or retrogression.

The heart has been too much set on a pedestal as the essential organ in the body when actually it is only one of many and at that one of the toughest, most resistant and most capable of recovery after serious disease. We recognize good recovery now in many cases of pulmonary tuberculosis, of acute renal involvement and of central nervous system disease with a return to full life activity; why should we not have the same point of view about recovery from heart disease in many cases?

THE ACUTE PROCESSES

What are the acute processes that may attack the heart to endanger life which are susceptible to quite adequate functional recovery? They include most commonly the acute rheumatic infection, the acute coronary episodes, especially frank coronary thrombosis and severe angina pectoris (often decubitus), and extreme tachycardia complicating heart disease. Less common events are Morgagni-Adams-Stokes attacks, actually dependent on coronary disease too, and rare instances of extreme tachycardia in persons with normal hearts in the form of auricular or ventricular paroxysmal tachycardia or of auricular fibrillation or flutter so severe that the heart may temporarily dilate and fail. In some of the cases of disturbing tachycardia thyrotoxicosis is the cause; the diseased thyrotoxic heart is one that is enlarged, progressing even to failure because of the severe recurrent strain of such tachycardia, not apparently from intrinsic heart disease. And there should finally be mentioned in this category severe pulmonary embolism and infarction, which is a serious threat to life not only in itself by the production of shock and through massive pulmonary involvement but also through severe strain on the right side of the heart, which may temporarily dilate and fail (the acute cor pulmonale).

I will discuss now in more detail the three commonest of the acute cardiac burdens, namely the acute rheumatic infection, coronary occlusion and extreme tachycardia in the presence of heart disease. Congestive failure that comes on insidiously or as the result of minor factors of strain in persons with heart disease does not of course belong here.

Many times I have seen children seriously or even desperately ill with acute rheumatic pancarditis who have recovered from their acute illnesses often to the surprise of family and doctor to return to a normal life and to survive for many years. One must therefore remember in treating and prognosing such cases that the majority do recover and that many will do well for years to come under good sensible care. Even heart murmurs, both systolic and diastolic, and heart enlargement (as determined by x-ray examination) may disappear with the subsidence of the cardiac dilatation due to the rheumatic myocarditis. The pericardial and endocardial involvements are often relatively unimportant parts of the clinical picture in acute cases. Of course, we must recognize that the ultimate prognosis in many of these cases is not good—only time will tell when another acute rheumatic infection may add its toll of strain to the heart already damaged. The heart may remain considerably enlarged or severe chronic valvular disease may develop to make the patient a partial or complete cripple. But I wish to emphasize that during the acute rheumatic illness one should keep an open mind about both the immediate and the ultimate prognosis no matter how sick the patient may seem to be at the moment.

The problem of cardiac prognosis becomes more important and more in need of revision when we arrive at the consideration of coronary disease. There is still widely held in medical circles as well as among the laity the idea that once coronary disease becomes manifest clinically the jig is up and that the victim must decide for himself whether he prefers to die "with his boots on" in a short while or as an invalid after a somewhat greater interval of time. This conception I meet among patients with appalling frequency. The great harm that has resulted from it is twofold. A good many of the more casual, rebellious or "hard boiled" patients take it on themselves to die "with their boots on," selfishly overlooking their obligations to their families, communities and themselves, and filling newspaper headlines with alarming accounts of their demise on some too strenuous pursuit in work or in play. Of course there are many exceptions, but I feel quite sure that the majority of the sudden deaths in coronary disease among active patients is still due to disregard of medical advice. That is, death from coronary disease is often preventable and a good many persons would survive many years longer than they do and still lead happy lives if they would only use common sense.

ATTITUDE OF THE PATIENT

The other side of the twofold picture of the harm done by the current attitude that coronary disease means either an early death in harness or complete invalidism is to me darker than what I have just presented. Thousands of patients have succumbed in spirit to the fear of death stalking them—they dare not raise a finger in work or active play again but sit at home or in their cars or at the movies or on the sands in southern Florida watching the hours and the days and the weeks and the months and the years go by, perhaps even free of all symptoms the vast bulk of the time, interesting themselves in fleeting pleasures and occupying themselves in filling out disability insurance blanks and watching the ticker tape of the stock markets. I do not mean thus to indict all or even the majority of persons who have become invalids after the appearance of coronary disease, but my remarks certainly apply to a very large number. There are persons who must live crippled lives but others who need not and should not. Surely there is a happy mean, and a wide one too, between the two extremes represented by these erroneous concepts of recent days.

Time and again a man or a woman is laid low by coronary thrombosis acutely and unexpectedly, or after previous related trouble. The immediate prognosis must remain guarded in even the mildest case during the first two or three weeks until the scar of the myocardial infarct is beginning to set and of course longer if the damage is great or serious complications supervene, but there are certain things that have recently been learned. If the patient survives the first month, the chances for recovery are fairly good and he will

probably live more than a year at least; if he survives the first year and is in fairly good health at the end of that time he should have a good many years ahead of him. Although he is not so good a risk as the man who has never shown coronary disease and although another attack, more severe and perhaps fatal, may strike him at any time, yet there is a good chance that he may go on for a long time and even succumb to some other ailment than heart disease. The prognosis in coronary thrombosis has steadily improved in the last decade, along with our knowledge. This is partly due to the fact that the sickest patients died off early when we first began to recognize the condition clinically, that the less severely ill have continued to live on longer than we at first thought they would, and that many very mild cases that we now recognize were not even being diagnosed ten or fifteen years ago.

Exactly the same thing is true of angina pectoris, mild or severe, with or without clinical evidence of actual occlusion with infarction. This symptom of coronary insufficiency may come and go, much to the surprise of many doctors as well as laymen. There may be a period of a few weeks of angina pectoris, simply on effort or rising to a crescendo of angina decubitus for a few days without prolonged pain, and subsiding suddenly or gradually melting away, doubtless representing some more or less slowly progressing occlusion without a definite myocardial infarct or with a very small one. Sometimes in such cases the diagnosis is doubted not alone by the layman but even by the doctor too, for there persists the old tradition that, once heart disease, especially involving the coronary arteries, always heart disease.

Nature is doing her utmost and very often successfully to reestablish by collaterals or by recanalization, or by both, an adequate coronary circulation. This spontaneous recovery, which tends to occur no matter what the treatment and which naturally makes one a bit skeptical of any newly heralded cure, can take place at any age. I saw it occur last year in an 84 year old man who came to us from Maine badly crippled by severe and increasing angina pectoris and expected by his friends and himself to end his days in the hospital; it happened that during the first few days with us, before we had a chance to try any particular therapy but rest, he began to improve. Within a few weeks he was well enough to return home and he has been well and active during the year that has passed, even without the very popular use of aminophyllin.

Every month now I see patients who come in for check-up examination after ten years or more, entirely free from heart symptoms and finding it hard to believe that they could ever have had what was so perfectly clear a decade or more ago, namely coronary thrombosis with myocardial infarction or angina pectoris of a lesser or greater degree. I have already reported survivals of from eighteen to twenty-five years after coronary thrombosis and such cases are now being more widely recognized. Of course the long survivors are still in the minority but if a man with angina pectoris at 55 can live to be 70 with ordinary care and good luck, as so often happens, why should he think at the onset of his trouble that he must die soon with his boots on or fold his hands sadly in his lap for fifteen miserable years of waiting for the end?

The moral of this tale, then, is obvious so far as the serious problem of prognosis and management of coronary disease is concerned. In the first place in nearly every case our cards should be on the table; a frank discussion should be held with the patient, generally an intelligent man, as to the whole matter, not leaving him in ignorance and awful suspense about the diagnosis or the sword of Damocles. Of course he may die the next day but so may we all in one way or another, by motor car if not otherwise. He should be advised of the use of rest and later of guarded exercise and work as circumstances require. He may have to stay in bed for a few weeks now and again later, he may have to quit work for a few months or a year, but that does not mean, in most cases certainly, that he must spend the rest of his days either in bed or as an invalid, with or without a nurse. His regular work may be too hard for him to resume or to continue, but often it isn't. Fortunately in these rather soft modern days there are still patients who refuse to quit work even though they know they may receive disability insurance when they do quit. Most such persons in my experience have modified their way of life and their work in such a way that they do avoid the heaviest part of their formerly too strenuous existence. They may find that they can keep at work if they but omit their rich food, tobacco and late hours. They serve as excellent controls for the large number who lay down their tools for good at the onset of trouble. An adequate study of the comparative durations of life in the two groups, that is among those still at work and among those at rest on the beaches, has not yet been made. It may well be that the invalids will outlive the others by a slight margin, other things being equal; but is the margin, even if considerable, worth the resignation of spirit and body, the loss of morale in the patient and in his family, and the loss of a trained mind to the community that so often follow the irrevocable decision to retire?

TEMPORARY VERSUS PERMANENT DISABILITY

The victim of coronary disease feeling very miserable at the time may be of course totally disabled; but should he consider himself or should he be considered permanently disabled as well? There lies the vital point at issue, the difference between the immediate and the ultimate prognosis in heart disease. A man who makes too early a decision to retire permanently may be at his wits' end a few years later when he has completely or largely recovered from his coronary symptoms: he must either try with some difficulty to regain his position or job or an interest in active living or he must resign himself to a dull life, now and then with a helpful avocation, or he must consciously or unconsciously simulate disease. Too often the last alternative is the result. The patient is fearful that if he should do anything in any way active mentally or physically he may drop dead, even though he has no symptoms at all from early morning to late at night, or he interprets every little ache or pain as the result of serious heart trouble when perhaps he has only a bit of gas in his stomach or bowel, a muscle twitch or a bursitis.

The reasons for the permanent surrender of patients who have had symptoms or signs of coronary disease are not far to seek. One of the most important and one that should be most amenable to correction is the attitude of the physician himself. This attitude is quite an innocent one on the part of the doctor and is held so widely that it has become a kind of habit or custom. He warns and advises his patient so seriously that he

rather prepares the victim for a pessimistic future, not realizing himself that recovery, more or less complete, is a very distinct possibility. It has been only in the last decade that the truth has been dawning on the minds even of the pioneer or advanced clinical workers in the field. In its follow-up the concept entertained by a few individuals some years ago is only now being confirmed by more ample experience. Even today recovery from the symptoms or signs of coronary disease is usually interpreted as meaning that the original diagnosis was wrong or that angina pectoris should be called false, pseudo, secondary or innocens if recovery follows —an unwise nomenclature.

The second important reason for the patient's surrender to permanent invalidism is a matter of personality. In this age of false values, rule by might, and loss of moral and spiritual stamina there is too easily a yielding to circumstance, a fatalistic point of view, a loss of courage. Persecution by disease, like persecution otherwise, is too often accepted as incontrovertible and irreparable. The spirit of our ancestors, the old New England tradition of a sane endurance of hardships, is tending to yield to a rather supine acceptance of oppression and invalidism. There is a spirit of moral cowardice in the air. It is about time that we recognize and combat it. Foolhardy neglect and bravado are not necessary to swing back to a more normal state. Some persons should still pass every winter in southern Florida to preserve their health and to prolong their life, but a good many go thither now simply because it is a habit, though no longer a good one.

At this point a strong word should be said against the common verdict, in law court and out, of permanent total disability of persons having coronary disease with angina pectoris or coronary thrombosis who happen to be disabled for a few weeks or months or even for a year or two. The word permanent is too permanent, often working havoc with the morale of the patient, the future of his work, the attitude of the physician and the management of disability insurance. Even the word total is often wrong. I have many patients who have kept at work for many years despite angina pectoris over all that period of time, useful citizens, continuing to earn more money than they spend, and living happier lives than other patients who have completely surrendered to their diagnosis and who live on the insurance companies, though they need not, and in constant dread lest doctors and insurance officials should one day decide that perhaps they are not very sick after all. Of course it is impossible for some patients to carry on their own work or to find any other that is easier, but there are many exceptions and it is of these exceptions that I speak. Disability insurance should most certainly be so adjusted that it can be assigned in part as well as in whole and temporarily as well as permanently. The faulty working of the assignment of disability insurance in cases of heart disease was in part the reason for the fraudulent cardiac racket that was recently exposed and punished in New York.

CORRECT DIAGNOSIS OF CORONARY DISEASE

Just a final word under the heading of the prognosis of coronary thrombosis and that is this: Coronary thrombosis used often to be called acute indigestion. Now, as Dr. Herrick has so ably pointed out, acute indigestion or some other noncardiac condition is too often called coronary thrombosis with the resulting uncertainty about the future both in prognosis and in management. Correct diagnosis is thus the first essential in prognosis.

HEART BLOCK

I have discussed the importance of distinguishing between the immediate and ultimate prognosis in the more common manifestations of coronary disease. The same principles should be applied in that rare but even more hazardous manifestation, namely the Morgagni-Adams-Stokes syndrome. In a number of cases I have watched the evolution, rapid or sometimes tediously slow, from the dangerous periods of frequent syncopal attacks to the stable fixation of complete heart block with normal health lasting for years.

PAROXYSMAL TACHYCARDIA

Paroxysmal tachycardia of various types or the onset of permanent auricular fibrillation may be fraught with great danger for the time being, especially if there is heart disease already present. Actual heart failure may supervene or simply distressing and sometimes very serious obstructive pulmonary congestion, as in mitral stenosis; but, with the subsidence of the paroxysm or the control of the ventricular rate in permanent auricular fibrillation by adequate digitalization, good health and reasonably normal activity are frequently restored for years to come. Here too, therefore, one must apply the principle of distinguishing between the immediate and the ultimate prognoses.

CONCLUSION

In closing I would speak briefly of certain factors that apply equally well to the immediate prognosis of heart disease and to the ultimate prognosis. They may be expressed, as in a paper I gave in Chicago last spring,[1] as follows: "The bigger the heart the more negligent the patient, and the more short lived the family the worse the prognosis." With respect to congestive failure, "The more obvious, serious and preventable the exciting factor, the better the ultimate prognosis," and congestion due to obstruction (mitral stenosis, tricuspid stenosis and constrictive pericarditis), either in the pulmonary or the systemic circulation, is less serious than congestion due to myocardial failure whether the underlying strain is acute (rheumatic infection, coronary thrombosis, excessive tachycardia) or chronic (valvular disease, systemic hypertension). Finally, the common and often unrecognized complication of pulmonary infarction in patients with heart disease, especially with heart failure, is very grave, threatening life even more than does the heart disease itself.

May I leave the concept that, although there are general rules which are helpful in the prognosis of heart disease in toto and that although nothing perhaps is even now more difficult in the practice of medicine than the prognosis of heart disease, a distinct advance can be effected by recognizing the fact that immediately serious and grave cardiac states may be followed by functional recovery so complete that the ultimate prognosis is good for many years after.

ADDENDUM.—Lest a wrong interpretation be put on my reference to sickness disability insurance I would add the present note. Certainly when angina pectoris is produced by the habitual occupation and life of a given individual, that individual is fully entitled to complete disability insurance payments so long as

1. White, P. D.: Aesculopian Bulletin of the North Side Branch of the Chicago Medical Society 28, April 1938.

he suffers such disability; the same is, of course, true for myocardial insufficiency. The important points that I have emphasized are, first, that coronary or other heart disease is often present without any disability; second, that disability from coronary disease (angina pectoris or even coronary thrombosis itself) is often but temporary, and third, that angina pectoris, though persistently recurrent, may be but slight in degree and, under reasonable precautions, compatible with a long life.

MENTAL ADJUSTMENTS TO HEART DISEASE

THE FACTORS INVOLVED IN DISABILITY

HOWARD B. SPRAGUE, M.D.

BOSTON

In heart disease, and peculiarly in coronary thrombosis, the comfort and contentment of the patient are largely conditioned by his adjustment to the problems of his livelihood. The factors which determine his disability, partial or complete, temporary or permanent, may be chiefly considered the following:

1. Physical incapacity as evidenced by congestive or anginal failure, or circulatory disturbances due to abnormal heart rhythms.

2. The character of the patient's work, which by necessity may keep the manual laborer from being able to carry on his trade.

3. Fear of heart disease as an incapacitating or fatal ailment. In such fear there is the normal human reaction to an unpredictable menace, but there is often the terror fostered by the gloomy predictions of the patient's medical advisers. In these predictions we recognize too commonly an attempt on the part of the doctor to protect himself if the patient suddenly dies, or to attribute to himself some virtue in his therapy if the patient does well while suffering from such a serious disease.

4. The influence of disability insurance in making it unnecessary to work in order to live, even though the income from this source may be too meager for the patient to maintain his standard of living.

5. The attitude of industry, largely mediated by the industrial compensation laws, which tend to be interpreted as holding employment responsible for any cardiovascular failure while a man is at work, thus making the cardiac patient unemployable.

There is, perhaps, no great credit due to the cardiac patient with minor lesions who is symptom free on effort, if he continues at his work, but my purpose in this paper is to give illustrative cases showing two sides of the disability problem. One group consists of patients who have carried on their labors for years with grave heart disease, and often with symptoms, and have refused to give up to wait in terror for death on some indefinite future day. The other group, with similar disease, often of less marked degree, have confessed defeat and devoted their lives to fear and worry over their eventual demise.

REPORT OF CASES

CASE 1.—In November 1921 a physician, then 59 years old, suffered a coronary thrombosis. He stayed in bed a month and rested for the winter. His recovery was complete and when he was seen in 1927 his only cardiac abnormalities were a moderate enlargement of the heart and a short systolic murmur at the apex. By moderating his activity somewhat and recognizing that mild dyspnea was a warning of fatigue, he has remained in active practice ever since. In 1935 he survived the perils of prostatectomy and in 1938 he recovered from a concussion of the brain and several fractured ribs received in an automobile accident. He has remained for seventeen years since his coronary occlusion the leading medical adviser and trusted friend of his community and at 75 years of age by no means considers himself as having finished his job.

CASE 2.—At the age of 17 a surgeon, now 58 years old, had rheumatic fever and developed aortic regurgitation. In spite of this he has led an extremely active life. In 1927 he had severe attacks of paroxysmal tachycardia which often incapacitated him from their frequency, severity and duration, which was at times as long as seventy-two hours. Even with this, he forced himself on occasions to operate and to see patients in his office during an attack. Their onset has been associated at times with collapse, substernal pain and dyspnea. The gradual dilatation of his aorta to a very large size has led to uncomfortable pressure between attacks and anginal pain on exertion. Fortunately, in the past three and one-half years it has been possible to shorten attacks by inducing vomiting with ipecac and more recently to prevent attacks by combined digitalis and quinidine. In the face of this degree of cardiovascular disease and recurrent temporary distress and incapacity this man has achieved the leadership of his specialty in his city and has headed his national society. Within recent years he has engaged in difficult big game fishing and to the present time remains an expert golfer.

CASE 3.—In 1931 a lawyer of 56 was examined because of hypertension. The previous year, evidence of left ventricular strain had been shown by an electrocardiogram, which revealed marked left axis deviation with an inversion of the T wave in lead 1. He was a very active and dynamic man who realized that his cardiovascular condition was not good but recognized the importance of work in maintaining his peace of mind. He has accepted restrictions but tends to overdo at times. In 1933 he developed early congestive failure with dyspnea and wheezing respiration on lying down, shortness of breath on exertion, and epigastric distress after eating. Digitalization relieved this but he has continued to work on the margin of his cardiac reserve. At times symptoms have forced him to bed for a few days; once with a gastric hemorrhage, but he repeatedly returns to his labors in the courts and travels constantly to various parts of the country on business. He does cooperate by taking regular vacations. His blood pressure remains high with slight alternation, his heart sounds are fair, an electrocardiogram shows progression of his myocardial disease and his maintenance dose of digitalis has had to be increased to 0.9 Gm. a week.

Would this man live longer if he quit completely? He might, but his happiness lies in being in the thick of the battle. He commanded a division as a general in the army in 1917 and he remains a fighter.

These men have faced their problems with the philosophy which is essential to success, namely the belief that the future is too indefinite to give up living in order to be prepared for death. The other group is that of the men who, in popular language, "can't take it."

CASE 4.—A man aged 43 in 1931 had a moderately severe coronary occlusion for which he was kept in bed for three months. His heart was a little enlarged but the sounds were of good quality when he was seen four and one-half months after his attack. Examination seven years later shows little, if any, enlargement of the heart. His blood pressure is 145 mm. systolic and 95 mm. diastolic and there is no evidence of heart failure. An electrocardiogram shows the remaining evidence of a posterior infarct. He has done no work. Because of vague symptoms of fatigue and a heavy feeling in his head he has been very inactive, has gained weight and smokes excessively. His sole support has been from disability insurance, the continuance of which has been his major source of worry. Fearful lest any attempt to return to his business as a security salesman might jeopardize his insurance payments, he spends his time with lawyers attempting to magnify his disability. Contentment

and morale have been lost, when a more compliant fatalism and a different insurance arrangement might have restored him to usefulness.

CASE 5.—A man aged 45 in 1920 developed precordial pain, which was diagnosed angina pectoris. The persistence of the pain eventually discouraged him and radiation to the arms increased his apprehension. The examination in 1923 was entirely negative but a rest of a year was advised. This retirement from active work became, unfortunately, permanent. Various pains occurred, including some in the abdomen for which an appendectomy was done and a normal appendix found. Fatigue, lack of ambition, dizziness and nervousness were prominent and health was continuously sought by annual trips to Florida, where he was able to walk and hunt. Repeated examinations have been negative but because of the original diagnosis of angina pectoris he has received disability insurance for fifteen years. As in the former instance, legal battles with their emphasis on disability have disturbed his life, and his existence has been an uncomfortable balance between compensable incapacity and sedentary survival.

CASE 6.—A man aged 34 in 1930, while working as a painter, made a sudden effort to support a falling ladder. He felt a snap in the region of the precordium with pain. His physician diagnosed heart disease with mitral insufficiency and an insurance company started payment of $100 a month after a legal action had determined that the patient was eligible, in spite of the competent medical testimony to the contrary. His father dropped dead at the age of 50. He did not work after the accident. When examined in 1938 his complaints were a burning feeling over the heart, worse on lying or sitting, leaning toward the left side. Effort caused exhaustion, faintness or sweating. His local physician was treating him constantly for heart disease. He was a healthy appearing muscular man weighing 190 pounds (86 Kg.). His heart was not enlarged and showed only a moderately loud cardiorespiratory systolic murmur. Marked sinus arrhythmia and tachycardia were present with a rate of from 100 to 150. Fluoroscopic and electrocardiographic examinations were negative. No heart disease could be found.

This case is an extreme example of the factors often involved in disability—an incident occurring at work, a diagnosis of heart disease, disability insurance which, while so inadequate that the patient's wife has to work, has been very helpful during the depression to both the patient and his doctor, the winning of a court judgment by the patient, fear and effort syndrome, and a very attenuated will to work.

CONCLUSIONS

Disability in heart disease depends on two things: the attitude of the patient in relation to his work and activity, and the type and severity of his symptoms as related to necessary effort. The rehabilitation of the cardiac patient, especially after coronary thrombosis, requires an intelligent appraisal of the signs and symptoms as they exist some months or a year after the acute breakdown, a will to work on the part of the patient, and a cooperative plan of a period of partial disability on the part of insurance companies and employees. Success depends on a restoration of confidence and, where disability insurance exists, on a proof to the patient that it is more desirable to work than not to.

It is a grave mistake for a physician to assume that coronary thrombosis necessarily implies complete and permanent disability. In all walks of life, but particularly in the executive departments of business and in the professions, many examples can be seen of the ability of people with heart disease to lead useful and comfortable lives. The obvious disablement of the majority of cardiac patients should not be added to by the fear implanted by medical advisers in the minds of a sizable minority who suffer from slight limitations.

LAWS REQUIRING PREMARITAL AND PREGNANCY TESTS FOR SYPHILIS

REASONS FOR AND AGAINST

JOHN A. KOLMER, M.D.
Professor of Medicine, Temple University School of Medicine; Director of the Research Institute of Cutaneous Medicine
PHILADELPHIA

Offhand it would appear that the laws enacted by nine states [1] and pending in several more which require blood tests for syphilis before the issuance of a marriage license are highly desirable as part of the present program for the control and eradication of the disease. The same is undoubtedly true in relation to pregnancy, three states [2] requiring blood tests of pregnant women, with similar bills now under consideration by several additional states. But a number of important questions both pro and con are involved in such legislation, which it is my purpose to discuss briefly, since physicians are frequently and properly consulted by legislators and other interested lay persons seeking information on the issues involved.

REASONS FOR THE LEGAL REQUIREMENT OF PREMARITAL BLOOD TESTS FOR SYPHILIS

1. *Because marriage inevitably involves syphilitic men and women in view of the high incidence of the disease.*

No one knows the true incidence of syphilis in the United States. Estimates have been based on the number of cases reported to health authorities and on serologic surveys conducted here and there on large numbers of persons. Unquestionably the number of cases reported to local and state health departments is far below the actual incidence because (1) many syphilitic persons are unaware of their infection and do not seek medical assistance or, knowing, neglect treatment; (2) large numbers escape diagnosis by both clinical and serologic examination, especially in the latent and chronic stages, and (3) many physicians refuse or neglect to report the disease.

On the basis of the results of blood tests it would appear that the incidence may vary from as low as 0.2 to 0.5 per cent among college students and the general population in this social class to as high as 20 to 30 per cent among other groups, especially southern Negroes. An incidence of 13.9 per cent of positive reactions has been reported in the U. S. Navy and Marine Corps, from 16 to 17 per cent among prisoners and about 19 per cent in the population of a large city such as New York as a whole with about 2 per cent for the responsible white portion.[3] But the various blood tests, even when conducted by experienced serologists, fail to detect from 10 to 40 per cent of syphilis in the later stages, including some which has had various amounts of treatment, so that Vonderlehr and his associates have estimated that about 10 per cent of the whole population of the United States have or have had syphilis.[3] Since about 91 per cent of those infected are believed to contract the disease between the ages of 16 and 40 years, it is readily understood that marriage involves a large number of syphilitic persons, particularly since at least 500,000 or 600,000 new cases are

1. Connecticut, Illinois, Kentucky, Michigan, New Hampshire, New Jersey, New York, Rhode Island and Wisconsin.
2. New Jersey, New York and Rhode Island.
3. Proceedings of Conference on Venereal Disease Control Work, Ven. Dis. Inform., 1936, supplement no. 3, pp. 125-133.

reported annually and a large number of additional ones are not detected or reported at all.

Very little information, however, has accumulated so far on the incidence of positive blood reactions among candidates for marriage. Dr. O. C. Wenger [4] of the U. S. Public Health Service reported 3.4 per cent among 2,578 antenuptial examinations made in Chicago during the latter half of 1937, and 3.9 per cent of all applicants examined in Illinois since the law went into effect were refused licenses because of two successive positive blood reactions.[5] These figures, however, do not indicate the frequency of syphilis among applicants for marriage licenses, because it is almost certain that men and women who know that they have syphilis with a positive blood reaction will not apply for marriage licenses in Illinois.

2. *Because legally required premarital blood tests will tend to lower the incidence of syphilis.*

I think it is a reasonable assumption that when men and women know that they must present to the state reports of negative blood reactions for syphilis before securing the legal right to marry, many will be deterred from risking infection by sexual exposure. In all truth I have not been greatly impressed by the factor of fear of infection alone as a deterrent to promiscuous sexual exposure and, as Father Schwitalla has recently stated, "knowledge alone does not make the saint and ignorance alone cannot make a sinner," but I believe that, when men and women realize that their infection may become known to the state, legally required prenuptial blood tests will be a factor in reducing the incidence of the disease. Furthermore, as will be discussed later, such tests will greatly aid the education of the public on the mechanism of genital and extragenital infection and, in my opinion, gradually reduce the incidence of the latter from kissing. In this connection it is well to remember that every person with syphilis has been calculated, in average terms, as being responsible for the infection of from one to three other persons. Premarital blood tests will inevitably contribute to the detection of much syphilis that would otherwise escape detection and most likely result in sufficient treatment at least to reduce the danger of transmission.

3. *Because blood tests are the most valuable single means for the detection of the disease, especially after the primary, or chancre, stage.*

Blood tests are the most valuable means of detection, particularly in the later stages, when the man or woman denies all knowledge of syphilitic infection, is free from clinical manifestations detectable by the average physician, without special skill in the disease, and is in apparent good health; in the acute early stages (first six months) when sufficient treatment has been taken to dissipate the external manifestations but the disease is still communicable to spouse and children, and in relapses, during which the danger of transmission is great.

Indeed, the detection of syphilis in relation to marriage and pregnancy is not infrequently entirely a matter of laboratory diagnosis but, even under the best of conditions, when the various blood tests are conducted by the authors of the respective methods themselves, the incidence of positive reactions for patients in all stages of the disease, including those who have received various amounts of treatment, may vary from 59 to 92.9 per cent. For example, in the first serologic survey conducted under the auspices of the U. S. Public Health Service in cooperation with the American Society of Clinical Pathologists,[6] the percentage varied from 65.8 to 88.2 in the laboratories of the authors of the various methods. In the second survey [7] it varied from 59 to 88.8 in the laboratories of the authors and from 35.3 to 93.2 in various state and local laboratories. In the third survey [8] it varied from 83.9 to 92.9 in the laboratories of the authors and from 38.7 to 90.7 in state laboratories. In the fourth survey [9] it varied from 70.5 to 83.9 in the laboratories of the authors and from 31.3 to 87.3 in state laboratories.

I mention these facts to show how blood tests themselves vary in their capacity to detect syphilis, to show the marked variations in relation to the methods employed and the skill and experience of the serologists conducting them and, finally, to emphasize the fact that states requiring blood tests before the issuance of a marriage license must assume the responsibility of seeing to it that the tests are conducted with one or, preferably, two of the best methods by serologists possessing a high degree of skill and experience.

4. *Because of the inadequacy or absence of a history of infection.*

That many syphilitic persons give no history of infection is so well known as scarcely to require comment. Many purposely deny all knowledge of infection or believe themselves to have fully recovered, but about 30 per cent of men and 60 per cent of women with chronic syphilis are honest in their denials and present no physical evidence of infection in the latent stage. Symptomless syphilis is relatively frequent, and about one man in every five and one woman in every three with syphilis fail to recognize the early symptoms and lesions. Certainly merely to ask applicants for marriage licenses whether or not they have a communicable disease is practically worthless so far as syphilis is concerned, and I surmise that this is true of gonorrhea as well.

5. *Because of the inadequacy of clinical detection of the disease.*

Of course the ability to detect syphilis clinically varies according to the special skill and experience of the physician. Even experts fail to detect atypical chancres when depending alone on clinical judgment, without the aid of dark field examinations for Spirochaeta pallida, and general practitioners have a still higher incidence of missed diagnoses, especially in the case of extragenital infections. Even with secondary syphilis, for which blood tests give almost 100 per cent of positive reactions, clinical diagnosis is not as easy as general impressions indicate, while with chronic latent syphilis diagnosis is frequently impossible because of the absence of detectable clinical manifestations. Furthermore, the incidence of missed clinical diagnoses in the chronic stages with signs and symptoms of disease is very high because the manifestations of chronic syphilis are so numerous and so varied. Under such circumstances properly conducted blood tests are invaluable aids to diagnosis in spite of their shortcomings and must play a part of great value in reducing the incidence of syphilitic marriages.

9. Evaluation of Serodiagnostic Tests for Syphilis, Ven. Dis. Inform., to be published.

I have previously shown from the results of serologic surveys how the blood tests vary in their detection of syphilis according to the methods employed and especially in relation to the skill and experience of the serologists conducting them, but I surmise that, if a commission of general practitioners as well as one of expert syphilologists were to undertake the diagnosis of the disease for a large group of persons including nonsyphilitic controls on the basis of histories and clinical examinations alone, there would be a goodly percentage of missed diagnoses. Such an experiment has never been conducted but would be well worth while in emphasizing the limited value of clinical diagnosis alone in the detection of syphilis, especially in the chronic stages of the disease. Serologists should take care against falling into an attitude of infallibility in the diagnosis of syphilis, and overconfidence on the part of clinicians is just as objectionable, as I well know from personal experience as a clinical syphilologist and serologist.

6. *Because premarital blood tests will reduce the incidence of transmission of syphilis to spouse and children.*

The danger of transmission of syphilis to spouse and children is greatest during the first five years after infection, especially if no treatment or inadequate treatment has been given. As shown by the Cooperative Clinical Group, about 61 per cent of a group of 368 spouses were found to have syphilis. It is impossible to state whether infection was transmitted during the early or late stages of the syphilis in the partner, but, as stated by Moore,[10] the danger of transmission to a marital partner from symptomless and latent syphilis is considerable.

In this connection, the marriage of syphilitic women is especially likely to result in transmission of the disease to children. It is almost certain that a man transmits the disease to the offspring by first infecting the mother; at least the instances of direct paternal transmission without maternal infection are extraordinarily infrequent. Indeed there is never absolute safety for the children if the mother is known to have the disease, and the value of premarital blood tests in the prevention of disasters to spouse and children cannot be minimized or denied.

7. *Because premarital blood tests reduce the incidence of the economic hazards of marriage from incapacity or early death of the spouse.*

In view of the fact that untreated or insufficiently treated syphilis carries the risk of ill health, incapacity for earning a livelihood and premature death, it is unfair for a woman unknowingly to marry a syphilitic man, because of the economic risks involved. The fiancée of a syphilitic man has at least the right to know the conditions and risks and make her decision when the circumstances have been explained to her. Furthermore, she has the right to know her chances of contracting the disease from her husband. Also the husband has a right to know his chances of contracting the disease by marriage with a syphilitic woman. In either event both have a right to know the chances of transmission of the disease to any children born of the marriage. When society is faced with the possibility of supporting the indigent syphilitic person incapacitated by the disease, or the spouse or the children, it has the right and the duty in my opinion of reducing as far as possible the risks involved, not only from the standpoint of the state but likewise from that of the welfare of the individual. Here is certainly one instance in which we are our "brother's keeper."

8. *Because premarital blood tests will reduce the incidence of divorce.*

I have no reliable statistics on syphilis as a cause of divorce, because so many persons are divorced on the grounds of incompatibility and the like as a mask for this cause, but undoubtedly the discovery that a spouse had syphilis before marriage and concealed the fact or was unaware of its existence is a frequent cause of divorce, to say nothing of the incidence of divorce due to syphilis contracted after marriage. Therefore I think that the prevention or delay of marriage involving syphilis by premarital blood tests is calculated to lower the incidence of divorce and all the evils it entails when due to this cause. Furthermore, such tests will inevitably reduce the disasters attending the remarriage of a man or woman following the death of or divorce of the spouse when infection occurred in the first marriage.

9. *Because premarital blood tests will greatly encourage the thorough treatment of syphilis.*

When syphilitic men and women realize that their chances of cure are about 90 per cent with thorough modern treatment in the early stages and that thorough treatment without biologic cure in both the early and the late stages renders marriage and procreation possible, especially if five or more years elapsed since infection, I think it is reasonable to expect that the legal requirement of premarital blood tests will encourage materially the thorough treatment of the disease, since the great majority of men and women look forward to the marriage state. I have enough confidence in human nature to believe that very few men and women wish knowingly and deliberately to endanger the health and lives of their spouses by syphilis.

10. *Because premarital blood tests are an excellent phase of the educational program against syphilis.*

Finally, I believe that premarital blood tests bring the subject of syphilis so prominently and intimately before both sexes that they cannot fail to stimulate a healthy interest in the disease and all it entails in relation to the individual and the public. Nothing is quite as good as a deep personal interest in acquiring a knowledge of any subject. Therefore I believe that these tests and all the publicity they entail will contribute materially to the education of the public on the subject of syphilis, to say nothing of inducing physicians to "brush up" on the subject of modern diagnosis and treatment, since the intelligent members of the public are never far behind the profession in keeping abreast of things of medical interest, especially those that may involve themselves in a very personal manner.

REASONS AGAINST THE LEGAL REQUIREMENT OF PREMARITAL BLOOD TESTS FOR SYPHILIS

Offhand it would appear that the reasons stated, possibly with additional considerations, constitute ample justification for the legal requirement of premarital blood tests for syphilis, but legislators are confronted with the necessity for carefully considering certain reasons against such legislation, some of which may be briefly summarized as follows:

1. *Because premarital blood tests may give nonspecific or falsely positive reactions.*

As shown in the first serologic survey,[6] complement fixation tests gave 53 per cent and flocculation tests 62.4 per cent of positive reactions with serums of fifty per-

10. Moore, J. E.: *The Modern Treatment of Syphilis*, Springfield, Ill., Charles C. Thomas, Publisher, 1933, p. 236.

sons with leprosy. With the serums of thirty-six persons with malaria, from 8.6 to 20.6 percent gave positive reactions. There are two diseases therefore occurring in the United States, and especially in the Southern states, which may cause positive reactions in the absence of syphilis.

Except for these two diseases and possibly acute infectious mononucleosis, no other diseases occur in the United States which are likely to cause positive reactions in the absence of syphilis when the tests are properly conducted. In a recent study of the serums of 441 tuberculous persons a complement fixation test gave no doubtful or falsely positive reactions, while six of seven flocculation tests gave a few atypical false doubtful and false positive reactions. It is evident therefore that tuberculous toxemia may contribute a confusing factor in the serologic diagnosis of syphilis, but this does not present a major problem in the clinical interpretation of results obtained with carefully conducted methods.[11]

In the first serologic survey six of thirteen methods gave no falsely positive reactions with the serums of sixty-two patients with malignant neoplastic diseases, while the remaining seven showed from 1.6 to 9.7 per cent of positive reactions. In fifty-one cases of jaundice, eight of the thirteen methods employed gave no falsely positive reactions, while such reactions occurred with from 2 to 3.9 per cent of the serums with the remaining five methods. In forty-six cases of natural or induced fever, six of the thirteen methods gave no falsely positive reactions, while in the remaining seven these occurred in from 2.2 to 8.9 per cent. In pregnancy and menstruation falsely positive reactions were of exceptional occurrence when the tests were properly conducted, as will be discussed shortly in more detail.

In other words, the serologic tests commonly employed at present are remarkably specific for syphilis when properly conducted, since the incidence of falsely positive reactions in tuberculosis, jaundice, malignant disease, fever and other diseases except leprosy and malaria is no higher than that for healthy persons, varying according to the method employed and, especially, the skill and experience of the serologists. In all four of the serologic surveys the incidence of falsely positive reactions observed in the laboratories of the authors of complement fixation and flocculation procedures varied from 0 to about 4 per cent, with the majority of the procedures showing no falsely positive reactions at all. In state and local laboratories the incidence varied from 0 to about 10 per cent, so that it cannot be denied that the various blood tests employed at present are capable of giving falsely positive reactions, especially the supersensitive flocculation procedures. As shown in the last, or fourth, survey (1938), however, a complement fixation and five flocculation procedures gave no falsely positive reactions at all in the laboratories of their authors, while one complement fixation and one flocculation test gave from 1 to 2 per cent of falsely positive reactions, indicating the high specificity of the tests when conducted under the best of conditions.

The fact remains that under routine conditions the blood tests for syphilis are capable of giving a small percentage of doubtful or falsely positive reactions; their incidence of course is in relation to the skill and experience of the serologists conducting them. To deny a man or woman the license to marry on the evidence of a positive blood reaction alone is risky and seriously open to criticism and objection. In the absence of clinical manifestations and a history at least suggestive of syphilis, it seems to me that the serologic evidence should be indisputable and based not on a single but on at least two positive reactions by two or more methods. As previously stated, those states legally requiring or contemplating premarital blood tests are obligated to see that the laboratories conducting them are approved as to the method or methods employed as well as the skill and experience of the personnel. Sooner or later serious legal complications are bound to arise from falsely positive reactions in applicants for marriage licenses.

I have observed during serologic surveys in the past two years several instances of falsely positive reactions in which a good deal of work was required to convince the subjects that they were not syphilitic. I know of several instances in which physicians instituted treatment on the basis of falsely positive blood reactions reported in such surveys. I am strongly in favor of serologic surveys for the detection of unsuspected syphilis, but I predict a small incidence of unnecessary treatment of nonsyphilitic persons as well as treatment accidents and injudicious therapy of syphilitic persons whose only indication for treatment has been a positive serologic reaction. These are by no means new or exceptional, since unnecessary or injudicious treatment on the basis of positive serologic tests is an old story in medicine, but I fear that one result of widespread serologic surveys will be to increase their incidence, especially in the case of physicians without special skill or experience with syphilis.

2. *Because positive blood reactions as the only evidence of syphilis may not always indicate a danger to marriage, especially in the case of thoroughly treated chronic syphilis.*

As previously stated, no physician can absolutely guarantee to a patient with syphilis that infection will not be transmitted by the marital relationship, but if the disease is of five or more years' duration, with thorough modern treatment for at least two years, the risks are almost infinitesimal even though the serologic reactions are positive. Whether or not the state can take a chance in its efforts to protect the spouse and children under such conditions is open to argument. Some excellent syphilologists are of the opinion that treatment may be terminated and marriage sanctioned. I am among those who believe that persistently positive serologic reactions are indicative of persistent infection requiring periodic courses of treatment for several additional years and in some instances for the rest of life to keep the infection latent [12] and that with such a program of treatment it is safe to sanction marriage and parenthood. Certainly no man or woman under such conditions must be permitted to regard his or her life as permanently blighted so far as the possibility of marriage is concerned, as in most instances he or she may marry with reasonable assurance of safety for spouse and children.

In other words, it seems to me that the state should exercise acceptable precautions in refusing a license when the applicant gives a positive serologic reaction on the basis that the presence of this reaction alone may not endanger the spouse, children or public. Just how such precaution should be exercised is not clear, but certain states require a physical examination along with an opinion from a licensed physician. Here, however, is a matter frequently requiring a more expert opinion

HARBORVIEW

than many physicians without special experience with syphilis are capable of giving, and, since the incidence of positive premarital reactions is comparatively low, it may be possible for each state adopting premarital tests to require in writing the sanction of a qualified expert of integrity before issuing a license for marriage under such conditions. On the other hand, since an arrangement of this kind may not be workable, the state may assume that its laws are for the benefit of the majority even though working a hardship on the individual and, with this as a recognized legal principle, simply refuse a license to all persons with positive serologic reactions when every reasonable precaution has been taken against false positive reactions.

3. *Because the legal requirement of premarital blood tests may discourage marriage and promote sexual promiscuity.*

A possible tendency to discourage marriage is a reason against legally required premarital blood tests worthy of serious consideration. Without doubt the tests are repugnant to a large number of men and women, who assume that they question their chastity. In time, however, the present educational program will reduce the widespread impression that syphilis always implies a lapse in sexual morality by showing that in eight or ten of every 100 cases of acquired syphilis the infection is extragenital (especially of the lips) and that every one is exposed in some degree to the dangers of infection in spite of respectability and morality.

The fact remains that many persons, including some who suspect or know that they are or have been syphilitic, will go for marriage [13] to states which do not require premarital examinations. Even worse is the strong probability that many of the latter will forego application for a marriage license and adopt common law marriage or a life of sexual promiscuity. Unfortunately this is particularly true of the social classes carrying the highest incidence of the disease.

4. *Because premarital blood tests alone may not detect syphilis, especially in its incubationary and primary stages.*

While blood tests alone may not detect syphilis, this does not necessarily constitute a valid reason against the legal adoption of premarital blood tests.

That a man or woman may marry during the incubation period of syphilis (ordinarily from three to four weeks after exposure and infection) with negative reactions is self evident, because enough time has not elapsed for the production of sufficient antibody or reagin in the blood for its detection. Under these conditions the applicant will slip through in spite of both physical examination and blood tests. Furthermore, the same thing is likely to occur unless the primary sore or chancre has been present for at least ten days and, even then, about 50 per cent of persons will give negative serologic reactions. A physical examination may reveal the sore, especially in men, but the sore readily and frequently escapes detection in women. Furthermore, many physicians still rely too much on their clinical judgment in differentiating syphilitic from nonsyphilitic sores on the genitilia and lips. In this connection I wish it were legally possible to require one or more dark field microscopic examinations for Spirochaeta pallida in all cases in which the true nature of the lesion is in doubt.

13. If residents of Rhode Island are married outside the state and within six months again take up residence in Rhode Island, they are required to conform to the provisions of the law requiring blood tests.

At least the premarital blood examinations should be made as near the date of issuance of the license as possible in order to reduce to a minimum the chance that candidates will slip through during the incubation and primary stages. Of the nine states now requiring premarital examinations, four (Illinois, Kentucky, Michigan and Wisconsin) specify that they must be made within fifteen days prior to issuance of the license; one (New York) specifies twenty days, two (New Hampshire and New Jersey) thirty days and two (Connecticut and Rhode Island) forty days. It seems to me that this period should not be longer than ten days, which ought to be sufficient for both physical examination and blood tests even when the latter require repetition. It would be still better to require the examinations within ten or fifteen days of marriage instead of within this period prior to the issuance of a license, because infection may and sometimes does occur in the time elapsing between the securing of a license and actual marriage.

Certainly every state adopting such legislation should require a medical examination by a licensed physician in addition to a blood test by the state or other approved laboratory, as it is self evident that the latter alone is insufficient. This is certainly true in the primary stage as well as in the latent and tertiary stages, when, it is remembered, serologic tests alone may fail to detect the disease. Apparently eight (Connecticut, Illinois, Kentucky, Michigan, New York, New Hampshire, New Jersey and Rhode Island) of the nine states with laws requiring serologic tests for syphilis before the issuance of a license to marry require a physical examination or at least a statement from a licensed physician that the patient is free from communicable syphilis, while apparently Wisconsin accepts a negative blood test alone as satisfactory evidence.

REASONS FOR THE LEGAL REQUIREMENT OF BLOOD TESTS FOR SYPHILIS DURING PREGNANCY OR AT DELIVERY

As previously stated, laws requiring blood tests of pregnant women have been passed by New Jersey, New York and Rhode Island, and it is to be hoped that similar ones will be adopted by every state, including provision for tests at the time of delivery in those frequent instances in which the woman has delayed obstetric care until labor has begun. Of course one of the main purposes of such laws is to detect syphilis and institute treatment as early as possible for the welfare of the child. When the blood test is made at delivery this opportunity is lost, but syphilis of the mother may be detected and subsequently treated.

1. *Because blood tests during pregnancy afford an excellent opportunity for detecting syphilis in both married and unmarried women.*

Tests possessing the maximum of sensitivity consistent with specificity must be employed, because syphilis in pregnant women is not as readily detected either clinically or serologically as in nonpregnant women and in men. Furthermore, although the question of pregnancy's causing falsely positive reactions is important, I can do no better than quote Moore: [14]

> There still persists a superstition, wholly unwarranted, that pregnancy is a frequent cause of false positive Wassermann reactions. This has been repeatedly demonstrated to be untrue, but the fallacy will not down. Pregnancy does not cause false positive Wassermanns; on the contrary, its effect is sometimes

14. Moore: The Modern Treatment of Syphilis, p. 250.

the reverse, and it may cause false negative tests in patients who have definite clinical evidences of syphilis. A strongly positive blood Wassermann in the pregnant woman, verified on repetition to avoid error in labelling or technique, is diagnostic of syphilis regardless of the presence or absence of a history or physical evidences of infection. The physician who disregards such a test and withholds antisyphilitic treatment from the mother accepts a grave responsibility for which he may be held accountable.

In the first serologic survey, covering blood tests in fifty-four cases of pregnancy, nine serologists reported no falsely positive reactions at all, while four reported an incidence of from 1.9 to 3.8 per cent.

2. *Because the detection and treatment of syphilis in pregnancy increases the chance of the birth of a nonsyphilitic child, with a reduction in the number of miscarriages and in infant mortality.*

As shown by Jeans,[15] 76 per cent of 1,712 normal women gave birth to healthy children, with only 9.7 per cent of miscarriages and 15 per cent of deaths during infancy. Among from 2,000 to 4,000 syphilitic women only 16.6 per cent gave birth to healthy children, with 30.3 per cent of miscarriages and an infant mortality of 30.2 per cent. Substantially similar results have been reported by the Cooperative Clinical Group. Usilton and her colleagues [16] have reported 2 per cent of stillbirths among nonsyphilitic mothers in Chicago, with 10 per cent among syphilitic women.

Since, in the average pregnant woman, the most searching physical examination fails to reveal any evidence of the existence of syphilitic infection, the best and usually the only way to recognize its presence is by means of the routine use of the blood Wassermann. This is now current practice in almost all large obstetrical clinics, the observed incidence of syphilis ranging, depending on the race and general type of clientele, from 3-23 percent. It should be current practice not only in clinic patients, but in patients of the private class as well; and no considerations of social level, expense, or confusion of morals with medical issues should be allowed to stand in the way of its performance in every pregnant woman. Only if syphilis is recognized in the pregnant woman can it be treated; only if it is treated, can congenital syphilis be prevented; and in the vast majority of instances, recognition of infection in the mother depends on the blood Wassermann, and on nothing else (Moore).

Available evidence indicates that proper treatment begun early, before the fifth month, bids fair to prevent infection of the fetus; if started after the fifth month it amounts to early treatment of an already existing infection, so that the high probability of the birth of a syphilitic infant or of a miscarriage is transformed into the practical certainty of the birth of a normal living child.

3. *Because the detection of syphilis in pregnancy results in the treatment of the mother, especially during subsequent pregnancies.*

The detection of syphilis in pregnancy enables the mother to benefit from treatment, with "cure" or "arrest" of her infection, as well as providing the indication for treatment during subsequent pregnancies for the protection of the fetus, especially if the reaction of the blood remains positive or if there is clinical evidence of persistent infection, regardless of the amount of previous treatment. Not infrequently it is difficult to persuade the mother, usually symptomless and in good health, to continue treatment after delivery, but this should be done whenever possible and particularly if her infection has occurred within two years. Furthermore, since the blood tests of some pregnant syphilitic women give falsely negative reactions, treatment "on suspicion" during pregnancy is frequently justified.

4. *Because the detection of syphilis in pregnancy may result in its detection and treatment in the child after birth.*

Positive serologic reactions during pregnancy naturally make the physician suspicious that the child will be syphilitic, especially if no treatment or insufficient treatment has been given. If there has been no opportunity for conducting the tests during pregnancy, the blood of both mother and child should be tested at delivery. In the case of the latter, cord blood may be employed although the test is not absolutely reliable, since a child with a negative reaction may subsequently show evidence of congenital syphilis, while one with a positive reaction may remain completely free from clinical or x-ray evidence of infection and subsequently give negative reactions.

5. *Because the detection of syphilis during pregnancy may lead to its detection and treatment in the father and other children.*

The detection of syphilis during pregnancy naturally leads to the examination of the father and any other children of the marriage, with the institution of treatment if infection is found.

Not every child of a syphilitic mother is born with syphilis. Some authorities believe, however, that in view of the difficulties in diagnosis during infancy and childhood all children born of syphilitic mothers should be treated, even if clinically and serologically free from infection; others believe that treatment should be given only when some positive or suggestive evidence of infection is present. The great difficulty is in proving that infection is absent in the children of syphilitic mothers, especially since the incidence of falsely negative blood reactions in symptomless congenital syphilis is particularly high; in case of doubt I administer treatment.

REASONS AGAINST THE LEGAL REQUIREMENT OF BLOOD TESTS FOR SYPHILIS DURING PREGNANCY OR AT DELIVERY

I know of no valid or important reasons against the legal requirement of blood tests during pregnancy or at delivery. As previously stated, falsely positive serologic reactions are no more likely to occur during pregnancy than in the case of men and nonpregnant women with acceptable methods skilfully carried out. It is true that many women, as well as their husbands, may object on the assumption that the test questions their morality, but, as previously stated, this is hardly a valid reason. Furthermore, when the blood of a woman has been tested and found to have a negative reaction in one pregnancy she may object to tests in later pregnancies, but this is no guaranty that she has escaped infection in the interim, especially if the husband is known or suspected to have acquired syphilis.

It may be that some women objecting to the legal requirement of blood tests during pregnancy will neglect to place themselves in the care of physicians and even elect to be delivered by a midwife. This is one of the reasons why I believe that it is advisable to require that the results of a blood test during pregnancy or at delivery shall be reported on all certificates of birth.

COMMENT

It is hoped that the discussions given both pro and con of the issues involved in relation to legally required blood tests before marriage and in pregnancy will prove of aid in the crystallization of opinion. It is not my purpose to discuss my personal views, but after due consideration of the issues involved, I find myself in favor of premarital examinations, including blood tests, and certainly in favor of blood tests during pregnancy or at delivery when conducted by methods possessing the maximum of sensitivity consistent with specificity and by serologists of skill and experience.

2101 Pine Street.

MATERNAL MORTALITY

EDWIN F. DAILY, M.D.

WASHINGTON, D. C.

Recent mortality reports seem to indicate that the intensive efforts by practicing physicians, local, state and federal health agencies and a great many lay groups to reduce the number of unnecessary maternal deaths in the United States are beginning to show their effects. Official statistics of the Bureau of the Census for the year 1937 give a maternal mortality rate of 49 per 10,000 live births. This rate is 14 per cent lower than the rate for 1936 (57), which was the previous low rate for the United States. If the maternal mortality rate for 1937 had remained the same as in 1936 there would have been 1,746 more maternal deaths in 1937 than actually occurred. This decrease in maternal mortality in 1937 is especially significant, since the death rate among women of child-bearing ages (from 15 to 49 years of age) from all other causes decreased by only 4 per cent. The birth rate in 1937 (17.0) was higher than the birth rate for 1936 (16.7).

Provisional statistics compiled by the United States Public Health Service indicate that the maternal mortality rate for 1938 will probably be more than 10 per cent lower than the relatively low rate for 1937.

Chart 1 shows the maternal mortality rates for the birth registration area of the United States for the period 1930 to 1938. The striking reduction in the rate for 1937 requires careful study, especially in view of the fact that the maternal mortality rate, although declining, was reduced on the average only about 3 per cent a year during the period 1930 to 1936. Chart 2 shows the states in which the maternal mortality rates for 1937 were significantly lower than for 1936 as shown by tests of statistical significance. The map shows seventeen states in which the decreases were sufficient to be statistically significant. The maternal mortality rates also decreased in twenty-six other states (including the District of Columbia) and increased in six states, but these changes were not sufficient to be of statistical significance.

The maternal mortality rate decreased fairly generally throughout the country, so that factors applicable to one area only cannot be considered of great importance.

Table 1 gives the maternal mortality rate by causes from 1930 to 1937.

The marked decrease in 1937 in the maternal death rate from infection should be noted, for, although theoretically a larger proportion of these deaths than of deaths from any other cause are preventable, the maternal mortality rate from sepsis in the past decade has decreased relatively little. The rates for hemorrhage, toxemias and all other causes were also significantly lower in 1937. The percentage of decrease of rates for infection, hemorrhage and other causes except toxemia was much greater in 1937 than their average decrease from 1930 to 1936.

The rate for toxemia, which had been dropping more rapidly than the rate for any other cause between 1930 and 1936, showed the smallest percentage of decrease in 1937.

Table 2 gives the average annual percentage of change in maternal mortality rates by cause from 1930 to 1936 and the percentage of change from 1936 to 1937.

The factors which may have been involved in bringing about the changes in rates which have been discussed will now be considered.

The general economic level of families in the United States may have been better in 1937 than in the five preceding years, but the prosperous years of the late 1920's brought about no such reduction in the maternal mortality rate. The importance of teaching women the value of proper diet during pregnancy and of assisting them to obtain certain protective foods is recognized by most public health agencies. The distribution of surplus commodities by the government and increasing efforts of local relief authorities to provide proper food for families in need of public assistance may well be a factor in improving the health of these families.

TABLE 1.—*Causes of Maternal Mortality; United States, 1930 to 1937*

Cause of Death	Maternal Deaths per 10,000 Live Births							
	1930	1931	1932	1933	1934	1935	1936	1937
All puerperal causes	67.3	66.1	63.3	61.9	59.3	58.2	56.8	48.9
Infection	24.4	25.1	23.4	23.5	23.6	24.0	21.5	16.9
Toxemias of pregnancy	18.5	16.8	15.2	14.7	13.8	12.6	13.0	12.3
Hemorrhage	6.9	6.8	6.6	6.4	6.5	6.4	6.5	6.0
All other causes	17.5	17.4	18.1	17.3	15.4	15.2	15.8	13.7

TABLE 2.—*Average Annual Percentage of Decrease in the Maternal Mortality Rate, United States, from 1930 to 1936; and Percentage of Decrease from 1936 to 1937*

Cause of Death	1930 to 1936*	1936 to 1937†
All puerperal causes	2.9	13.9
Infection	1.6	21.4
Toxemias of pregnancy	6.0	5.4
Hemorrhage	1.2	7.7
All other causes	2.5	13.3

* Calculated by the ordinary equation for geometric progression: $\log. y = 100 (a + b x)$.

† Calculated: $\frac{100 \text{ (1936 rate} - \text{1937 rate)}}{\text{1936 rate}}$

The only recent scientific discovery or addition to the therapeutic armamentarium of the obstetrician is sulfanilamide. This drug in the future will be likely to save many lives from certain types of puerperal infection, but its use in 1937 for the treatment of puerperal infection was not widespread in the United States.

The avoidance of pregnancy among women suffering with heart disease, tuberculosis, chronic nephritis or other chronic organic disease will reduce the number of maternal deaths in this group of women and the number of therapeutic abortions. Many persons believe that the wide distribution of birth control information will result in a decrease in the incidence of abortions induced for other than therapeutic purposes. Accurate statistics on illegally induced abortions are not available in the United States to support or disprove these con-

From the Children's Bureau, United States Department of Labor.

tentions. That the unsuccessful practice of birth control may result in an increased number of induced abortions was shown in a recent study by the Milbank Memorial Fund of 6,554 pregnancies occurring in more than 1,500 women in a Midwestern city.[1] In this group illegal abortion was ten times as frequent in the termination of accidental pregnancies as in the termination of pregnancies which occurred when no contraception was used.

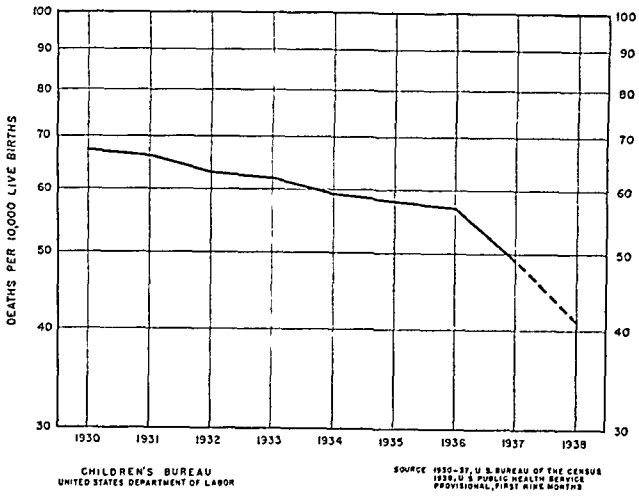

Fig. 1.—Trend of maternal mortality in the United States; 1930 to 1938.

The percentage of births in hospitals in the United States increased from 41 per cent in 1936 to 45 per cent in 1937. Better facilities for transportation and the rapid spread of group hospital insurance and lay education may have had something to do with this. If all women were delivered in properly equipped and administered maternity hospitals it would be ideal for both patient and physician, but unfortunately there are too few hospitals in the United States today that can be considered entirely satisfactory for the care of maternity patients.

Educators in the field of obstetrics have anticipated for many years that when a sufficient number of physicians trained in the past ten or fifteen years were in practice their appreciation of the value of prenatal care and the dangers of certain complications of pregnancy would result in better obstetric care. The constant efforts of the American Medical Association to raise the level of education in the medical schools and to improve and extend intern and resident services in hospitals have of course had far reaching effect in improving all phases of medical activities. Undoubtedly the improved education of medical graduates in recent years has been a definitely favorable factor. Postgraduate education in obstetrics provided in recent years for local medical groups in almost every state has resulted in a great increase in the professional interest in problems of maternal care. The demands by these practicing physicians for additional clinical postgraduate obstetric training and experience have been steadily increasing. The application of adequate, intelligent maternal care is spreading, and there is an increasing appreciation by general practitioners of the need for consultation with obstetric specialists for certain of the more serious complications of pregnancy and childbirth.

One of the most important factors in the recent reduction of the maternal death rate has been the nation-wide educational campaign, directed to present and future mothers. Newspapers, radio, magazines and even movies have bombarded the public with the benefits of proper medical and hospital care for the maternity patient. Some 20,000 public health nurses have relentlessly preached the gospel "See your doctor early in this pregnancy," have assisted the families they serve in carrying out the instructions of their physicians, have taught hygiene in the home, have helped prepare for the delivery and often have assisted the physician during labor. Dr. J. Whitridge Williams often used to say that when the women of America realize the value and need for adequate maternity care they will demand it, and only then will they get it. The women of America are demanding better care and more and more of them are receiving it each year.

The extension and improvement of state and local public services for maternal and child health made possible under the provisions of the Social Security Act, beginning early in 1936 and increasing in effect in subsequent years, have made possible additional postgraduate medical education and have stimulated a nationwide campaign of lay education. From these funds the states have provided medical, nursing and dental care to ever increasing numbers of maternity patients and have raised the standards of maternal care in all parts of the country. The states recently reported that 69 per cent of the 1,207 permanent antepartum clinical centers administered by state health agencies or by local health agencies under supervision of state health agencies have been established since social security appropriations for maternal and child health services became available. Thirty-eight per cent of the 1,984 counties with public health nursing services for mothers and children under the supervision of the state health agencies have established this service since the social security funds were made available.

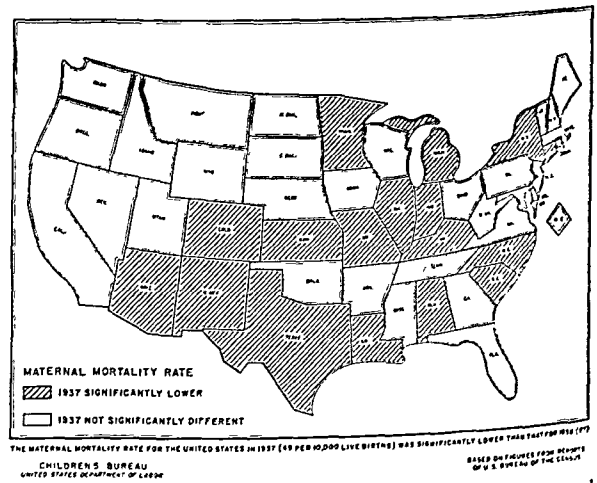

Fig. 2.—Significant changes in maternal mortality rates; 1937 compared with 1936.

The carefully conducted studies and surveys of maternal mortality which have been made in recent years have had a profound effect in every community undertaking them. Only the physicians who have given hours and days of their time each month to studying all the factors concerned with the maternal deaths in their communities and who have sought the best methods for preventing these deaths in the future can fully appreciate what their efforts have accomplished during

1. Milbank Memorial Fund Quarterly, January 1939, p. 69.

the past few years. The American Committee on Maternal Welfare, Inc., with its component organizations, and the state maternal welfare committees have been leaders in assisting the public health agencies and the medical profession in coordinating their efforts. The Children's Bureau has recently prepared a new simplified record form for community studies of maternal mortality.[2]

Though it is expected that the number of maternal deaths will continue to decrease in 1938 and 1939, the downward trend in maternal mortality as shown on statistical charts issued by the Bureau of the Census may not continue in the United States after 1939 for two reasons, which relate to the reporting and classification of causes of deaths and not to the results of maternal care.

The standard death certificate as revised for use in 1940 requires the physician to record on the death certificate all instances of pregnancy within three months prior to death. As a result, pregnancy will be mentioned in connection with a larger number of deaths than at the present time. There are at present about 14,000 deaths annually in the United States concerning which pregnancy is mentioned on the death certificate as a cause of death. These deaths are usually termed "deaths associated with pregnancy and childbirth."

Of the 14,296 deaths so certified in 1935, 87.7 per cent were assigned to puerperal causes, that is were classified as directly due to pregnancy and childbirth, and 12.3 per cent were assigned to nonpuerperal causes. The latter group included deaths due to criminal abortion and deaths due to some disease such as tuberculosis, diabetes, chronic nephritis or syphilis, which might or might not have proved fatal if the women had not become pregnant. The occurrence of pregnancy in a woman with active or recently arrested tuberculosis, chronic nephritis, heart disease and so forth is likely to exacerbate the underlying disease and so be responsible for a number of deaths among this group of women. The more complete information to be obtained in 1940 may result in the assignment of a larger number of deaths to the puerperal conditions.

The International List of Causes of Death as revised for use in 1940 will result in the assignment to puerperal causes of a larger proportion of the deaths associated with pregnancy and childbirth. At the meeting of the International Commission for the Decennial Revision of the International Nomenclature of Diseases held in Paris in October 1938, it was agreed by all countries represented that after 1940 criminal abortions would be classified as due to puerperal causes. Under the revision of the list now in use (the 1929 revision) criminal abortions are classified under homicide. There are only about 250 deaths annually in the United States which are stated to be due to criminal abortions. Several changes were made in the list and several definitions were adopted which will result in more satisfactory information on causes of maternal mortality. An abortion was defined as the termination of a uterine pregnancy at less than seven months (twenty-eight weeks) of gestation. Under the procedure of the 1929 revision of the list many deaths occurring at less than thirty-eight weeks of gestation have been classified as abortions.

It is expected for the following reasons that after 1940 far more information will be available to serve as a basis for understanding the causes of maternal mortality and for planning work directed toward the reduction of maternal deaths:

1. The requirement that physicians mention pregnancy on the death certificate of all women who were pregnant within three months prior to death will give a new view of the real importance of pregnancy as a factor in relation to death.

2. The 1940 revision of the International List of Causes of Death will afford more satisfactory information on the causes of death directly due to pregnancy and childbirth.

3. Another great forward step is the addition of a medical section to the standard stillbirth certificate and of the medical section to the live-birth certificate recommended by the American Committee on Maternal Welfare and the Children's Bureau.

The significant changes that have occurred in the maternal mortality rate in 1937 offer real encouragement for the future. The adequate body of statistical fact that will be afforded for the years after 1940 gives every hope that far greater forward steps may be taken than in the past.

[2] These record forms, with instructions for making such studies, may be obtained from the Children's Bureau.

SPONTANEOUS REMISSIONS IN SCHIZOPHRENIA

(CINCINNATI GENERAL HOSPITAL, 1933-1937)

JULES GELPERIN, M.D.
CINCINNATI

Spontaneous remissions occur with a certain frequency in cases diagnosed as schizophrenia. This is an important factor in evaluating results obtained from insulin and metrazol treatment. The present study was made in order to determine the incidence of this phenomenon at the Cincinnati General Hospital. Those patients who had been diagnosed as having schizophrenia in the Cincinnati General Hospital for a five year period (1933-1937) were investigated to obtain information regarding the duration of the hospital stay, the outcome of the episode and the duration of the remission in the improved patient.

The patients were first admitted to the Psychiatric Pavilion of the Cincinnati General Hospital and subsequently were either discharged from the Cincinnati General Hospital or transferred to the nearby State Psychiatric Hospital. This study was continued on the patients transferred to the state hospital. Patients who had been given metrazol or insulin therapy were not included in this study. The patients were divided into four groups according to the duration of their symptoms prior to admission to the hospital:

1. Symptoms of less than six months' duration.
2. Symptoms of from six to twenty-four months' duration.
3. Symptoms of more than twenty-four months' duration.
4. Symptoms for an indeterminate period.

Of 103 patients whose symptoms were of less than six months' duration prior to hospital admission, fifty-three were discharged from the hospital improved. Twenty-one were admitted for a period, then transferred to the State Hospital and subsequently discharged as improved. Three were admitted twice each; their first stay ranged from three to seven weeks and their second

From the Department of Psychiatry, University of Cincinnati College of Medicine.

admission resulted in transfer to the State Hospital, from which they were discharged as improved. The duration of hospital residence of these twenty-four patients was as follows: for periods ranging up to six months there were thirteen patients, from six to twelve months six patients and from twelve to twenty-four months five patients. In summary there were twenty-seven admissions for these twenty-four patients with a range of hospital stay, comprising that in the Cincinnati General Hospital and State Hospital, of from three and one-half months to four and one-half years, with an average hospital stay of 9.9 months per admission. Twenty-nine patients were discharged from the Cincinnati General Hospital improved after a hospital stay which ranged from one to twelve weeks and averaged 4.1 weeks. These twenty-nine patients are classed according to the duration of their hospital stay as follows: for periods ranging up to four weeks, twenty patients; from five to eight weeks, eight patients; one patient remained in the hospital for eleven weeks. The fifty-three patients who were finally discharged as improved had an average hospital stay of 5.4 months per admission.

There were fifty patients of this group who were unimproved. Two died in the Cincinnati General Hospital after an average hospital stay of less than four

The Outcome in 235 Cases of Schizophrenia Without Drastic Treatment

Duration of Symptoms Prior to Admission	Number of Cases	Number of Unimproved Patients	Number of Deaths	Number Improved	Per Cent Improved	Average Hospital Stay in Improved Cases
0 to 6 mo.....	103	43	7	53	51.4	5.4 mo.
8 to 24 mo.....	30	18	3	9	30.0	8.0 mo.
24 mo.+.....	90	59	4	27	30.0	12.9 mo.
Undetermined	12	7	0	5	41.6	4.6 mo.
Total.....	235	127	14	94	40.0	7.7 mo.

weeks and five died in the State Hospital subsequent to transfer after an average hospital stay of twenty-five months. Forty-three patients were transferred to the State Hospital and the length of their residence there to date (July 1, 1938) is as follows: from six to twelve months, four patients; from twelve to twenty-four months, nine patients; from twenty-four to thirty-six months, thirteen patients; from thirty-six to forty-eight months, five patients; and from forty-eight to sixty months, twelve patients. Seventeen patients were discharged from the Cincinnati General Hospital unimproved after an average hospital stay of less than four weeks. These could not be followed and the clinical outcome was therefore not determined.

Of thirty patients whose symptoms were present for from six to twenty-four months prior to hospital admission there were nine discharged as improved. One was discharged from the Cincinnati General Hospital after being there for five weeks. Eight were transferred to the State Hospital after hospital stays which ranged from five to sixty-four weeks, the average stay in the two hospitals being 8.9 months. Four of this group remained in hospitals less than six months and four for between six and twelve months.

There were twenty-one patients who did not improve. Eighteen were transferred to the State Hospital and are still there. Two of these patients have been confined to hospitals for less than six months, six from twelve to twenty-four months, one for twenty-eight months and nine from thirty-six to sixty months. Three others who did not improve were transferred to the State Hospital and died after an average stay of 11.3 months. Three patients were discharged from the Cincinnati General Hospital unimproved after an average stay of less than two weeks. Their subsequent clinical course could not be determined.

Of ninety patients whose symptoms were present for more than twenty-four months prior to hospital admission, twenty-seven were discharged improved. Twenty-four were transferred to the State Hospital and thence discharged improved. These twenty-four patients required hospital residence as follows: thirteen for less than six months, three for from six to twelve months, six for from twelve to thirty-six months, and the remaining two for thirty-nine and fifty-six months respectively. The combined hospital stays ranged from three to fifty-one months and averaged 14.1 months. Three patients were discharged from the Cincinnati General Hospital improved after from two to three weeks. The average hospital stay was 12.9 months for the twenty-seven patients.

There were sixty-three patients who were unimproved. Four were transferred to the State Hospital and died there after an average stay of thirty-one months. Fifty-nine patients were transferred to the State Hospital and are still there. These patients have been in the hospital for the following periods: nine for less than twelve months, twenty for from twelve to thirty-six months and thirty for from thirty-six to sixty months. Twenty-six patients were unimproved and were discharged from the Cincinnati General Hospital after an average stay of less than three weeks. Their subsequent clinical course could not be determined.

Of twelve patients whose symptoms were of undetermined duration, five were improved at the time of discharge from the hospital. Three were transferred to the State Hospital and later discharged improved after hospital stays ranging from two to eight months and averaging 5.3 months. Two patients were discharged from the Cincinnati General Hospital improved after hospital stays of one week and fifteen weeks.

Seven patients were unimproved. Seven were transferred to the State Hospital and are still there after periods ranging from four months to five years. Five patients were discharged from the Cincinnati General Hospital unimproved after an average stay of less than three weeks. Their subsequent course could not be determined.

SUBSEQUENT COURSE OF THE IMPROVED PATIENTS

Attempts were made to interview all of the ninety-four improved patients. They were traced by means of addresses given on admission to the Cincinnati General Hospital, and only twenty-one could be located in the community. Three had reentered the hospital because of recurrence of the psychosis, twelve months, twenty-two months and four years after the first discharge.

The eighteen patients (fourteen males and four females) who remained in the community with no return of the psychosis were interviewed. Eleven of the men were working full time and three part time. One female was working full time outside her home and three were carrying on their household duties. These improved patients had remained out of the hospital from one to fifty-five months. The average length

of remission for the eighteen patients was 25.9 months. No one of these eighteen had residuals of their psychotic episode and all could be classed as recoveries.

COMMENT

The validity of a survey of this type depends on several factors including the sampling of patients, the diagnostic criteria, the criteria of a remission and a follow-up study.

The Psychiatric Pavilion at the Cincinnati General Hospital is the only psychiatric hospital in Cincinnati to which the individuals from the lower income group may be directly admitted. Patients for commitment to the State Hospital from Cincinnati are first studied at the Cincinnati General Hospital and later transferred. Because of these facts many patients were observed suffering both acutely and chronically from schizophrenia.

During the five year period (1933-1937) the diagnostic standards were rather constant. The diagnosis of schizophrenia was made because of certain signs and symptoms and at no time during this period did the diagnosis depend on the ultimate result, for in the great majority of patients the outcome was not known to the physician who made the original diagnosis.

The ability to make a good adjustment outside an institution was the main factor in determining whether or not a patient had had a remission. The return of the patient to the level of adjustment which he enjoyed prior to the onset of his obvious difficulties, as far as this could be determined, was considered to be a reasonable and fair basis for judging remission. It is well known that the great majority of these individuals have certain personality difficulties, which might be said to be present prior to what appears to be the obvious onset of the schizophrenic episode. It is hardly to be expected that a complete cure will result in such a case by the waxing and waning of the psychosis.

SUMMARY

The results of this survey are summarized in the accompanying table.

1. The cases of schizophrenia admitted to the psychiatric service of the Cincinnati General Hospital over a five year period were analyzed to determine the percentage of spontaneous remissions.

2. Ninety-four patients of a total of 235 were discharged as improved, after no other treatment than superficial psychotherapy.

3. Of the ninety-four patients who improved, twenty-one could be found in the vicinity. They were interviewed at varying periods after their remission and eighteen were then classed as recoveries. The average period that this recovery was maintained was greater than two years.

4. Thirty-five of the ninety-four patients who had improved obtained the remission during their stay at the Cincinnati General Hospital and therefore did not require State Hospital care.

CONCLUSIONS

1. Spontaneous remission occurs with enough frequency in schizophrenia that its incidence may be favorably compared with the remissions obtained from the shock therapy (insulin, metrazol) of schizophrenia.

2. Those patients who enter the hospital soon after the onset of symptoms have an apparently better prognosis than those who enter late. This factor is not necessarily related to the treatment.

CHANGES IN SERUM POTASSIUM IN CERTAIN ALLERGIC STATES

HOWARD A. RUSK, M.D.
T. E. WEICHSELBAUM, PH.D.
AND
MICHAEL SOMOGYI, PH.D.
WITH THE TECHNICAL ASSISTANCE OF ERNEST SIMMS
ST. LOUIS

About a year ago one of us [1] reported six cases of chronic urticaria in which definite improvement was attained by the administration of a low sodium, high potassium, acid ash diet with the addition of from 4 to 6 Gm. of potassium chloride daily. Recently Bloom [2] has reported similar results in a variant group of allergic persons.

This clinical success in a small series of cases prompted a study of possible chemical changes involved. The first requisite in our work was information as to the normal potassium content of blood serum. The values reported in the literature, however, show too wide discrepancies and variations to be uncritically accepted, especially in view of the fact that most of them were obtained by the method of Kramer and Tisdall,[3] the unreliability of which (and of its modifications) has been clearly pointed out by Van Slyke and Peters.[4] By means of an improved micro method (which is based on the gasometric determinations of a well defined mixture of potassium-silver-cobaltinitrite compounds), we were able to obtain results that agreed ±1 per cent with control determinations done by the macro platinic chloride method. The details of the method are to be reported shortly.

TABLE 1.—*The Potassium Content of Blood Serum in Healthy Persons and in Some Allergic Patients*

No. of Patients	Condition of Subject	Mg. of Potassium per 100 Cc. of Serum		
		Lowest	Highest	Average
35	Healthy	17.9	20.6	19.5
20	Urticaria, acute and chronic	22.0	25.3	23.4
10	Bronchial asthma, asymptomatic period	21.3	25.1	23.6
7	Bronchial asthma, acute attack	24.0	25.5	24.4

The serum potassium values of thirty-five normal persons, determined by this procedure, are well in line with the normal values obtained by MacCallum,[5] who employed a classic platinic chloride method, and incidentally agree with the results of a few more recent investigators.[6] The maximum difference in the serum potassium of healthy persons, as shown in table 1, is less than 3 mg. per hundred cubic centimeters, in contrast to the wide range of variations reported by several other authors.[7]

With this orientation on hand we proceeded to study the serum potassium in allergic conditions. The first group comprised twenty patients with acute and chronic

urticaria, for whom repeated analyses were performed. As may be seen in table 1, every person in this group showed a definite elevation of the potassium content of the serum above the normal. It is noteworthy that with subsidence of the urticarial lesions the serum potassium recedes to appreciably lower levels and stays there until a subsequent attack.

The following three cases are illustrative of the phenomenon involved:

CASE 1.—A man aged 25 who had severe dermographism and urticaria had a fasting serum potassium content on three consecutive days of 22.2, 22.1 and 22.2 mg. per hundred cubic centimeters. On the morning of the third day he was rubbed down with a rough towel, with the production of urticarial wheals over the entire body. One hour after this procedure a rise in the serum potassium to 24 mg. was found.

CASE 2.—A man aged 50 had chronic urticaria of fifteen years' duration, with a serum potassium content of 23.8 mg. per hundred cubic centimeters. After two weeks of a diet low in sodium and high in potassium, with 4 Gm. of potassium chloride daily, he became symptom free and the serum potassium content dropped to 20.6 mg. He has remained symptom free since on a low sodium, high potassium regimen.

CASE 3.—A man aged 28 with severe urticaria of nine months' duration could be kept symptom free with large doses of potassium chloride, but the administration of potassium chloride had to be discontinued because of gastric distress. The urticaria was found to be the result of a sensitivity to acrylic aldehyde originating from the combustion of a glycerin-treated cigaret. When examined the patient showed mild urticaria, and a sample of blood obtained at this time had a serum potassium content of 21.8 mg. per hundred cubic centimeters. He then smoked six glycerin-treated cigarets; marked urticarial wheals developed on the face and hands, and one hour later the serum potassium content had risen to 25.3 mg.

The other patients in our series with urticaria have shown similar values.

As a second allergic condition we studied bronchial asthma. Hoffman and Jacobs [6] found in seven cases of this disease elevated serum potassium levels. Our studies made in ten cases during asymptomatic periods showed a definite increase in serum potassium. In seven cases observations were made in acute attacks.

TABLE 2.—*Summary of Experiment 1 (Case 4)*

Time	Blood Sugar (Whole Blood) (True Sugar) Mg. per 100 Cc.	Lactic Acid (Whole Blood) Mg. per 100 Cc.	Potassium (Serum) Mg. per 100 Cc.
Fasting	69	11.6	23.4
6 min. after exercise	72	59.1	23.7
30 min. after exercise	87	18.2	22.3
Immediately after exercise after 50 Gm. of dextrose.	69	55.3	22.5
30 min. after exercise	81		
25 min. after insulin	63	15.0	21.7
Immediately after exercise.	79	60.0	20.8

It may be noted in table 1 that, whereas the peak value in an acute attack was not appreciably higher than the maximum during remission, in an acute attack even the lowest value found was very high. It is not apparent from table 1 that four of the seven patients in an acute attack are also represented in the group of ten studied during asymptomatic periods. It may be stated that every one of these four, while showing increased potassium levels during remission, showed a further elevation in the acute attack.

Harrop and Benedict [8] and Briggs and his associates [9] reported in 1924 that insulin causes a drop in the serum potassium level of men, dogs and rabbits. A number of other workers have confirmed this finding. We were interested in the therapeutic significance of this phenomenon in certain allergic disorders in which elevated serum potassium levels are characteristic. The premise of our studies was the assumption that the increased potassium content of the serum indicated a depletion of tissue cells of their normal potassium content and, furthermore, that such factors as depress the level of the serum potassium accomplish this effect by driving potassium back into the cells, thereby helping to reestablish the electrolyte equilibrium. Among the agents we employed were insulin and dextrose, administered in conjunction with potassium salts. We have had patients with urticaria and a few with asthma who responded very favorably to this treatment.

TABLE 3.—*Summary of Experiment 2 (Case 4)*

Time	Blood Sugar (Whole Blood) (True Sugar) Mg. per 100 Cc.	Lactic Acid (Whole Blood) Mg. per 100 Cc.	Potassium (Serum) Mg. per 100 Cc.
Fasting	78	9.3	23.6
"	77	45.0	24.9
"	62	11.3	24.8
"	29	7.8	23.7
Immediately after exercise	60	45.6	23.9
35 min. after exercise	72	14.3	20.9

The following case is illustrative:

CASE 4.—A youth aged 16, who weighed 150 pounds (68 Kg.) and was 5 feet 11 inches (180 cm.) tall, had had severe asthma for fourteen years, requiring frequent injections of epinephrine for relief. For a few months he had needed four doses of epinephrine and morphine daily to gain any degree of comfort. At various times he had been tested cutaneously with innumerable pollens and other substances and showed sensitivity to a large group. He had a markedly dermagraphic skin. He had been subjected to various allergic regimens without any success. It was found from the history and experiments that he could bring on an attack of asthma by a short period of violent exercise.

EXPERIMENT 1.—October 15, with a resting potassium content of 23.4 mg. per hundred cubic centimeters, the patient ran up and down a steep flight of fourteen stairs for eight minutes. A rather severe attack of wheezing was brought on. Six minutes after exercise a blood sample was taken (table 2). In thirty minutes the wheezing was over. Fifty Gm. of dextrose was given by mouth, and fifteen minutes later the exercise was repeated. Very mild wheezing ensued, which was over in ten minutes. A blood sample was taken immediately after the exercise. Thirty minutes after the mild wheezing had stopped, 8 units of insulin was given intravenously and 50 Gm. of dextrose was given by mouth. Twenty-five minutes later the exercise was repeated; no wheezing resulted, and the patient volunteered the information that he did not suffer nearly the amount of muscular exhaustion and dyspnea as he had previously.

For some time it has been known that ammonium chloride increases the urinary excretion of potassium. We attempted to determine how this drug would affect this patient:

EXPERIMENT 2.—October 16 the patient was given 9.5 Gm. of ammonium chloride, and October 17 the dose was repeated. October 18 at 10 a. m. the patient was free from symptoms and was subjected to the same exercise as in experiment 1. He completed his period of exercise with great difficulty and at the end of this time was wheezing violently; he continued to wheeze for about one hour. At the end of this time he was given 8 units of insulin intravenously and 25 Gm. of dextrose; thirty minutes later he was given another 25 Gm. of dextrose, and the same period of exercise was repeated. There was little or no wheezing, and normal breathing was established fifteen minutes after exercise.

8. Harrop, G. A., Jr., and Benedict, E. M.: J. Biol. Chem. 59: 683 (April) 1924.
9. Briggs, A. P.; Kocchig, I.; Doisy, E. A., and Weber, C. J.: J. Biol. Chem. 58: 721 (Jan.) 1924.

In summarizing the experiments on this patient it is clearly demonstrated that the tolerance to exercise was markedly increased by the administration of dextrose and, to an even greater degree, by dextrose and insulin. The lowering effect on the serum potassium may be noted in the figures of both experiments. The serum potassium response of the patient to insulin, dextrose and epinephrine was determined, but detailed reports will not be given here, as there are insufficient data at present for a quantitative comparison with a normal subject. However, it might be stated that all these substances caused a marked fall in the serum potassium level.

November 30 the patient suffered a severe attack. When he entered the hospital at 6 p. m. he had a serum potassium content of 25.5 mg. per hundred cubic centimeters. He was given 25 units of insulin intravenously and 50 Gm. of dextrose by mouth. Fifty minutes later the symptoms were very much relieved, so much in fact that there was no need for epinephrine. He remained symptom free all night. The serum potassium content in the morning was 25.6 mg. On this date we decided to start giving him potassium and insulin daily. He was given 6 units of insulin subcutaneously thirty minutes before breakfast, with 20 grains (1.3 Gm.) of enteric-coated potassium chloride. He received during the day 50 grains (3.2 Gm.) more of potassium chloride, and thirty minutes before supper he received 6 units more of insulin. Before he retired another 20 grains of potassium chloride was administered. There was no restriction of diet except that he was advised to avoid fried foods and other high fat foods, which seemed to upset his digestion. This regimen was continued for ten weeks, and during this time the patient did not have an asthmatic attack. The longest previous period that he had been free from asthma in fourteen years, according to his history, was two weeks. Potassium balance studies are being carried out.

Keys[10] has recently reported the potassium-lowering effect of large doses of insulin. He ascribes the phenomenon not to insulin but to epinephrine, which is excreted in response to the hypoglycemia that follows the injection of insulin. To probe this concept we gave a patient 8 units of insulin intravenously but preceded it by the oral administration of 50 Gm. of dextrose in order to forestall the development of hypoglycemia. The results are shown in table 4.

The trivial drop in the blood sugar content can scarcely be regarded as hypoglycemia, yet the serum potassium showed a distinct decrease.

TABLE 4.—*Potassium-Lowering Effect of Insulin*

Time	Blood Sugar (Whole Blood) (True Sugar) Mg. per 100 Cc.	Potassium (Serum) Mg. per 100 Cc.
Before insulin	70	24.5
30 minutes after insulin	65	22.8

Since dextrose alone causes a drop in the serum potassium content of dogs,[11] we tried the effect of 100 Gm. of dextrose given orally on a human subject. The results are recorded in table 5.

It may be noted that the serum potassium content decreased from the initial 20.5 mg. per hundred cubic centimeters to 16.7 mg. in two hours after the ingestion of 100 Gm. of dextrose, a drop of 19 per cent. In the same interval the blood sugar content rose from 79 to 126 mg. per hundred cubic centimeters. There had been no hypoglycemia to cause an increased secretion of epinephrine. When, however, compensatory hypoglycemia did occur, four hours after the ingestion of dextrose, the serum potassium had risen by 17 per cent above the lowest level.

The studies have been extended to the quantitative relationship be[illegible] the dose of insulin and its [illegible]. In this place we wish only to mention the noteworthy phenomenon that this relationship is entirely different during acute attacks and in symptom-free periods in allergic persons. The following examples are illustrative of this fact:

TABLE 5.—*Potassium-Lowering Effect of Dextrose*

Time After Ingestion of Dextrose, Minutes	Blood Sugar (Whole Blood) (True Sugar) Mg. per 100 Cc.	Potassium (Serum) Mg. per 100 Cc.
0	79	20.5
30	120	20.9
60	118	19.0
90	127	18.0
120	126	16.7
180	107	19.0
240	53	19.6

A patient with severe asthma showed in an asymptomatic period a serum potassium content of 22 mg. per hundred cubic centimeters; forty minutes after the intravenous administration of 10 units of insulin the potassium content decreased to 16.6 mg., a drop of 25 per cent. In an asthmatic attack, on the other hand, when the serum potassium content was 24.5 mg. per hundred cubic centimeters, an identical dose of insulin effected only a drop to 23.7 mg., corresponding to a little over 3 per cent.

In a case of marked chronic urticaria of six months' duration, during an attack in which almost the entire body was covered with wheals, there was an initial serum potassium content of 23.7 mg. per hundred cubic centimeters, and fifty minutes after 20 units of insulin had been given intravenously the value was 21.7 mg., a drop of 9 per cent. During a relatively symptom free period, with a resting potassium content of 22.6 mg. per hundred cubic centimeters, forty minutes after 10 units of insulin had been given intravenously the value was 19.5 mg., a drop of 14 per cent.

We have studied the effect of dextrose, insulin and epinephrine on the blood potassium in several of our cases of urticaria and asthma during symptom-free periods and have found that all three substances cause substantial lowering of the serum potassium content. A discussion of the quantitative differences from the normal subject must await further work. When the patient is in an urticarial or asthmatic attack the potassium-lowering effect of insulin and epinephrine is markedly decreased.

The mechanisms involved in potassium metabolism are at present little understood, but it is an established fact that the bulk of body potassium is stored inside the cells, and the blood serum is primarily a medium of potassium transport. By providing an excess of potassium in the diet and by giving potassium chloride by mouth, one is making available a source of potassium replacement for the body cells, which we have postulated as being depleted of their potassium content. Experiments are now in progress to test the validity of this postulation.

SUMMARY

The results of our studies, to the present time, may be summarized as follows:

1. In patients with acute and chronic urticaria there is an increase in the serum potassium, and with the subsidence of clinical symptoms the blood potassium content falls.

10. Keys, Ancel: Am. J. Physiol. **123**: 608 (Sept.) 1938.
11. Flock, Eunice; Bollmann, J. L.; Mann, F. C., and Kendall, E. C.: J. Biol. Chem. **125**: 57 (Sept.) 1938.

2. The same phenomenon has been observed in patients with bronchial asthma.

3. In an urticarial or asthmatic attack the serum potassium-lowering effect of insulin and epinephrine is markedly decreased.

Certain allergic patients with urticarial and asthmatic manifestations show definite relief of symptoms with potassium chloride alone or potassium chloride and insulin, while other patients do not seem to be benefited by this regimen. At the present status of our investigation we have not been able to determine which allergic patients will show a therapeutic response; with further studies, now under way, we hope to determine criteria for selection.

HISTAMINASE IN THE TREATMENT OF SERUM SICKNESS

LEE FOSHAY, M.D.
CINCINNATI
AND
O. E. HAGEBUSCH, M.D.
ST. LOUIS

The recent studies of Roth and Horton [1] demonstrated that the oral administration of the enzyme histaminase would prevent the occurrence of local inflammation and edema in patients susceptible to cold allergy after their hands and forearms were plunged into cold water. After discussing their cases with Dr. Roth we decided to test the effect of the enzyme in controlling or preventing the local and general symptoms of serum sickness. For several years one of us (L. F.) has entertained the hypothesis that the major phenomena of serum sickness are due to a release of histamine, or a histamine-like substance, in the tissues and into the circulation consequent on the union of serum protein antigens and antibodies. The irregularity of appearance of the disturbance and the great variability of its clinical aspects in different persons might depend on different rates of production of antibodies to the separate fractional antigenic components and on the differential solubilities and adsorption capacities of the various tissues of the recipients for these different antigenic components of the serums. This in brief is the hypothesis that we thought might be tested for validity by giving histaminase to patients with serum sickness.

Best [2] first observed the presence of a histamine inactivating substance in tissues. With McHenry [3] he prepared a stable powder which contained the active substance in high concentration, and because of its enzyme-like action these workers proposed the name histaminase.

The producers of the compound state that it consists of ferments derived from the intestinal mucosa which are destructive to histamine and histamine-like substances.[4] It was furnished in enteric coated tablets, each containing 5 histamine detoxicating units, and in ampules for intramuscular injection, each dose representing 1 histamine detoxicating unit. One unit represents that quantity of the material which is capable of detoxicating 1 mg. of histamine hydrochloride during twenty-four hours at 37 C.

The tables show the essential data in condensed form. The first eight patients received only the enteric coated tablets by mouth before meals. The first patient had had serum sickness due to horse serum a few years previously. On the present occasion the eyes were closed, the lips were enormously edematous and the itching from universal urticaria was intense. All symptoms were relieved in about twenty-two hours. Patchy areas of erythema that did not itch continued for three days. Although this attack began as unusually severe serum sickness, the patient volunteered the statement that it was nothing compared with his previous attack. The second patient was not relieved. The third patient obtained complete relief from itching, fever, arthralgias and myalgias thirty-six hours after beginning to take the tablets. At this time the initial treatment of 30 cc. of horse serum was followed by the administration of 60 cc. of goat serum. No further serum sickness occurred.

The fourth patient was utterly wretched, with fever and universal urticaria with violent itching. Unlike the other patients she had had epinephrine, but it never gave complete relief. After starting to take the tablets, two immediately followed by one thrice daily, she slept all night but had a few scattered residual wheals the next morning. Two tablets thrice daily were then given, and the last trace of erythema disappeared in about six hours. This relief lasted for two days. To see whether this was a spontaneous recovery, administration of the tablets was stopped. Urticaria recurred in about twenty hours. This patient weighed well over 200 pounds (91 Kg.). The preliminary dose was obviously too small. The fifth patient obtained no relief whatever despite the relatively large dose. The amount of serum given and the apparent severity of the disturbance were the same as they were for the sixth patient, who obtained complete relief in thirty-six hours after taking three tablets at the first dose, and then one thrice daily, before meals, for the next two days. Again, in order to see whether this might be a spontaneous early cessation, the administration was stopped. Urticaria reappeared in fourteen hours, but arthralgias did not recur. At this time three tablets were given at once, followed in four hours by two more. The urticaria had disappeared again when the last dose was taken. It never recurred.

The seventh patient had had seven injections of a commercially prepared refined horse serum in eight days. On the eighth day bacteremia persisted, and both ophthalmic and intradermal tests with normal horse serum gave slight positive responses. Because of the gravity of the situation it was decided to risk giving 60 cc. of unrefined serum by vein. This was followed in half an hour by an anaphylactic reaction of moderate severity, consisting of universal erythema, dyspnea, hyperpnea, tachycardia, severe headache and chills. Relief was obtained with one subcutaneous injection of 0.5 cc. of epinephrine. Histaminase tablets were then given at the rate of one thrice daily. For the next nine consecutive days additional unrefined horse serum was given intramuscularly in daily or twice daily doses of

From the Department of Bacteriology, University of Cincinnati College of Medicine, and the Cincinnati General Hospital.

4. The supply of histaminase, called T: 360, was furnished by the Winthrop Chemical Company, Inc.

from 30 to 60 cc. The last tablet each day was given at about 5:15 p. m. Each morning at 7 a. m. there were moderate sized Arthus reactions at the sites of the intramuscular injections. The skin was red, indurated and thickened to approximately one half inch, with a central pale area about 1½ inches in diameter. The areas of induration were about 4 by 5 inches in diameter. The first daily tablet was given at 7 a. m. By 9 a. m. each day the skin at these sites was normal in color and in thickness, and no trace of the reactions remained save a brilliant red line about 1 mm. thick, which marked the peripheral boundary between the former areas and the uninvolved normal adjacent skin. It was thought by all who saw the patient that without the histaminase it would have been impossible to continue the daily injections of serum.

In the eighth patient severe serum sickness developed on the seventh day after injection of 60 cc. of serum. Treatment with histaminase was begun on the second day of symptoms. She received a total of twenty tablets at the rate of one three times a day. There was marked relief from the itching and malaise in twenty-four hours. Mild symptoms and signs persisted for another day, to the fourth day of the disorder.

recession of signs and symptoms, which finally disappeared completely and permanently at the seventy-second hour.

The fourth patient had unusually severe serum sickness, with universal giant urticaria, intolerable itching, fever and edema of the face, hands and feet. Hourly injections of epinephrine brought slight transient relief. The administration of histaminase was begun on the second day, the contents of two ampules being given in one injection. A similar dose was given twelve hours later. Marked relief was noted twelve hours after the first injection. At twenty-four hours after the first injection there were no symptoms or signs of serum sickness and there was no return of either. The disturbance was mild in the fifth patient, consisting of scattered urticaria and large diffuse patches of intense erythema. The first injection of histaminase was given eight hours after the onset. Marked relief and permanent, complete disappearance of the urticaria occurred within forty-eight hours. The last signs and symptoms had disappeared before the seventy-second hour.

The sixth patient had accelerated serum sickness of great severity, with the onset eight and one half hours after the administration of serum. There were gen-

TABLE 1.—*The Effect of Histaminase Administered Orally to Seven Patients with Severe Serum Sickness*

Case No.	Patient	Age	Sex	Dose of Serum, Cc.	Day After Injection of Serum the Serum Sickness Appeared	Severity	Day of Serum Sickness Use of Histaminase Was Begun	Administration of Tablets	Total Number of Tablets	Comment
1	W. M.	50	♂	30	5th	Very severe	2d	1 t.i.d.	12	Relief in less than 24 hr.; patchy erythema dispelled in 3 days
2	K. C.	25	♂	60	5th	Severe	1st	1 t.i.d.	10	No change; lasted from 5 to 6 days
3	D. O.	21	♀	90	3d	Severe	1st	1 t.i.d.	21	All signs and symptoms dispelled in 36 hr.

5	D. D.	16	♀	180	6th	Severe	2d	2 q.i.d.	30	No change; symptoms lasted from 4 to 5 days; hives from 8 to 9 days
6	C. C.	43	♂	180	8th	Severe	2d	See text	17	Complete relief in 36 hr.
7	S. S.	42	♀	440	9th	Very severe	1st	1 t.i.d.	40	Complete relief in 10 hr.; maintained despite 9 additional days of continued intramuscular injections of serum
8	C. M.	62	♀	60	7th	Severe	2d	1 t.i.d.	20	Marked relief in 24 hr.; mild symptoms persisted to the fourth day

The next group, of thirteen patients, received the injectable form of histaminase intramuscularly. Four also received the tablets orally. The first patient had universal erythema and urticaria, intolerable itching, edema of the glottis and marked difficulty in expiration. Epinephrine was given in doses of 1 cc. every fifteen to twenty minutes for more than ten hours, with only partial relief. The administration of histaminase was begun on the third day, with noticeable relief in twelve hours, complete relief in eighteen hours and permanent disappearance of all symptoms in forty-eight hours. The second patient had scattered urticaria, moderately intense itching, erythema about the mouth and swelling around the eyes and lids. Histaminase was injected soon after the onset. No other medication was given. There was no progression of the disturbance after the first ampule was injected, and complete and permanent relief, with disappearance of all visible signs, was obtained within forty-eight hours. The third patient had very severe serum sickness, with generalized urticaria, intense itching, severe arthralgias, vomiting, pain in the chest and edema of the glottis. Histaminase was given eight hours after the onset. There was marked relief in thirty-six hours, followed by a gradual, steady

eralized urticaria and erythema, intolerable itching, severe arthralgias, swelling of the face and so much edema of the glottis that it was feared a tracheotomy might become necessary. Large injections of epinephrine brought moderate relief from the dyspnea, but the drug caused severe nausea and persistent vomiting and seemed to add to the existing wretchedness. One hour after the onset the histaminase from two ampules was given intramuscularly in one injection, and the dose was repeated in four hours. The contents of additional single ampules were injected six, twelve and twenty hours after the first dose. Practically all symptoms and signs had disappeared by the twentieth hour and there was complete disappearance by the twenty-fourth hour. The contents of one ampule were given on each of the two following days. There was no recurrence. The seventh patient was only moderately ill, with urticaria, moderate arthralgias and edema of the face, hands and feet. The administration of histaminase was begun twelve hours after the onset. Both forms were employed. Three tablets three times a day were given until twenty had been taken. The contents of two ampules were given at the first injection, followed by those of one ampule night and morning until the con-

tents of five had been injected. Recession of symptoms and signs was noted at the eighteenth hour, and the patient was normal again by the thirty-sixth hour.

The eighth patient had only moderately severe serum sickness, chiefly urticaria. Histaminase was given on the first day. The dose was the contents of one ampule daily for five days. Moderate relief was obtained at the forty-eighth hour, and there was only an occasional hive after the ninety-sixth hour. The ninth patient had only moderate erythema and urticaria but unusually severe arthralgias involving all joints, including the mandibular. She was given the contents of two ampules of histaminase in a single injection night and morning for four doses and the contents of a single ampule the following day. She was also given three tablets three times a day for the first two days and two additional tablets on the third day. The response was prompt. Relief was almost complete by the thirty-sixth hour, and no signs or symptoms persisted beyond the forty-eighth hour. The tenth patient had severe generalized urticaria, arthralgias of the knees, ankles and wrists and edema of the eyelids. Histaminase was given almost twelve hours after the onset. The contents of four ampules were given the first day, of three the second day and of one the third day. He also received two tablets a day for three days. Relief was noted twenty minutes after the first injection. Serum sickness was entirely dispelled before the end of the third day.

The eleventh patient had the usual symptoms of severe serum sickness, with onset five days after the administration of 180 cc. of horse serum. Administration of tablets was begun on the second day of symptoms and continued for three days, the patient taking four, five and four tablets daily, a total of thirteen. During these three days the severity of the symptoms progressed steadily. On the night of the fourth day of serum sickness the contents of one ampule were given. This dose was continued morning and night for three additional injections. There was marked relief from itching by the morning of the fifth day, and urticaria disappeared permanently that evening. Arthralgias persisted for another twenty-four hours. The patient looked and felt normal forty-eight hours after the first injection. There was no recurrence of symptoms or signs.

The twelfth patient had serum sickness of mild to moderate severity on the tenth day after injection of 1,500 units of tetanus antitoxin. He was without fever but had universal erythema, diffusely scattered small urticarial wheals, with intense itching, and nausea. Treatment was begun on the first day of serum sickness and consisted of the injection of the contents of one ampule morning and night for five doses and the administration of one tablet three times a day until a total of seventeen had been taken. The itching was markedly relieved nine hours after the first injection but continued to a mild degree for two days, associated with persisting mild erythema without urticarial wheals. All symptoms had disappeared by the third day. This patient attributed some of his nausea and vomiting to the ingested tablets, but since nausea had been severe before histaminase was first given a causal relation could not be established.

A thirteenth patient, a girl aged 6 years, had severe serum sickness following serum treatment for scarlatina. She lived in a small outlying town. Histaminase was sent to her physician, who reported verbally that a very good result was obtained, but we do not have the detailed data on this case.

Except as noted, all patients received unconcentrated, unrefined horse serum.

TABLE 2.—*The Effect of Intramuscular Injections of Histaminase on Serum Sickness*

Case No.	Patient	Age	Sex	Dose of Serum, Cc.	Day After Injection of Serum the Serum Sickness Appeared	Severity	Day of Serum Sickness Use of Histaminase Was Begun	Administration of Ampules and Tablets	Total Dose	Comment
1	H. B.	25	♂	30	10th	Very severe	3d	1 b.i.d	6	Relief in 18 hrs.; began at 12th hr.; urticaria gone at 48th hr.

USE IN PROPHYLAXIS OF SERUM SICKNESS

We also tried to see whether histaminase could be used in prophylaxis. Not enough patients have been treated prophylactically to permit any feeling other than optimism concerning the results of further trials. We can report at present the results with only eight patients. Four received 60 cc. of an unrefined antibrucella horse serum, one received 90 cc. of the same serum, two others received 30 cc. of unrefined antitularense horse serum and the eighth received a total of 453,000 units of gas gangrene antitoxin. The dosage of histaminase was as follows: on the day preceding the administration of serum each patient received the contents of one ampule morning and night by intramuscular injection and three tablets, one before each meal. Each patient received the contents of one ampule on the day of serum administration and one each day for the two following days, a total of five ampules a patient. The oral administration of tablets was continued at the rate of one three times a day until a total of twenty tablets had been taken.

None of the first five patients showed any evidence whatever of serum sickness at any time after the administration of serum. The sixth patient, who had received 90 cc. of serum, showed very mild serum sickness on the eleventh day after the first injection of serum. The manifestations consisted only of urticaria limited to the arms and trunk. Since she was in an extremely critical situation because of her infection, irrational and then comatose, with a temperature of 107 F., it was not considered advisable to let the serum sickness run its course to observe how mild it might be as a result of the prophylactic measures. She was given the contents of one ampule at once. The urticaria disappeared in eight hours. The contents of another ampule was given on the following day to insure against the return of symptoms. No manifestations of serum sickness occurred.

The seventh patient, a bacteriologist, had had horse serum on two previous occasions, with very severe, almost fatal anaphylaxis at the time of the second administration. Horse serum was abandoned, and treatment was completed with goat serum. Seven months later he contracted moderately severe brucellosis. The administration of goat serum was selected as the treatment of choice. He received three histaminase tablets three times a day for one day prior to the administration of serum and continued with the same dose for the first day of the administration of serum. He took two more tablets the next morning, so that he had a total of twenty. Trial intradermal and subcutaneous injections of goat serum were made, with positive responses. He received 60 cc. of goat serum, by vein, in two equal doses on consecutive days. No immediate reactions occurred. On the seventh day urticarial wheals appeared at the sites of the previous test injections, but nowhere else. These wheals waxed and waned daily for seven days before they disappeared. There were no general signs or symptoms of serum sickness and, although additional histaminase tablets were in his possession, none were taken.

The eighth patient suffered four compound fractures from a fall down an elevator shaft. A prophylactic injection of combined tetanus and gas gangrene antitoxin was given on the day of the fall and repeated on the following day. On the fifth day after injury cultures of Welch's bacilli were obtained from a wound in the thigh. Administration of antitoxin was begun at once. On the next day these bacilli were isolated from a wound of the wrist. Antitoxin was administered for five days, from the fifth to the ninth after the injury and the initial prophylactic injection of serum. A total of 453,000 units of antitoxin was given. Administration of histaminase was begun on the seventh day after the injury, the second day of therapeutic administration, of antitoxin, and was continued for seven days. Ampules were used at the rate of one twice a day for five days and one once a day for two days, a total of twelve. Tablets were given at the rate of three twice a day for five days and three once a day for two days, a total of thirty-six. At no time was any difficulty encountered in administering serum, nor were there ever any signs or symptoms of serum sickness. An accurately recorded experience with 450 patients treated with antitularense serum shows that serum sickness occurred in 54 per cent. A similar experience with 200 patients treated for brucellosis shows that antibrucella horse serum caused an incidence of serum sickness of 73 per cent. Although the series must be extended considerably before any conclusion can be drawn, the probability is very small that any five consecutive patients can receive these serums in the quantities given and all escape serum sickness.

TABLE 3.—*Prophylactic Use of Histaminase*

Case No.	Amount of Serum, Cc.	Day Before Serum		Day of Serum and Thereafter		Totals		Comment
		Ampules	Tablets	Ampules	Tablets	Ampules	Tablets	
1	60	1 b.i.d.	1 t.i.d.	1 q.d. × 3	1 t.i.d.	5	20	No serum sickness occurred
2	30	1 b.i.d.	1 t.i.d.	1 q.d. × 3	1 t.i.d.	5	20	No serum sickness occurred
3	60	1 b.i.d.	1 t.i.d.	1 q.d. × 3	1 t.i.d.	5	20	No serum sickness occurred

COMMENT

There was no failure to obtain a striking therapeutic response in any of thirteen patients with serum sickness, selected at random, when the injectable form of the material was administered. There were two complete failures to obtain the anticipated effect when the

mode of administration was limited to the use of enteric coated tablets. Except as noted, no patient received any other form of treatment. We realize that when an active substance is administered only in the form of enteric coated tablets the expected response may not occur because of failures of digestion and absorption. Although other possible causes for failure of response have been considered, we believe that our two failures were most probably due to impermeability of the enteric coating.

Although every patient was examined carefully and questioned in great detail, no evidence of unpleasant or untoward effects could be elicited except in the few cases in which the contents of two ampules were administered in a single injection in the amount of saline diluent recommended for one ampule. In these cases there were smarting and transient pain at the sites of injection.

We cannot say that our hypothesis concerning the cause and nature of serum sickness has been verified by the present small experience, although certainly it has not been weakened.

We recommend that further trials be made of this substance in the treatment of serum sickness, so that additional knowledge can be had concerning its value in the hands of others. Our initial experience with it indicates to us that it is the only rational, genuinely effective and safe remedy known for this distressing condition.

With regard to dosage for future patients, we think that our most frequently used schedule for the injectable material is probably just about right in the usual cases of moderate to severe forms of the disorder. One ampule morning and night for five injections has seemed adequate. For unusually severe forms the dose should be increased, certainly for the first day and possibly for the second day. Since as many as five tablets three times a day has been used for patients with other conditions without provoking any recognizable untoward effects, it would seem sensible to increase the dose beyond the amounts we have recorded for patients who are to receive only tablets. Four or five tablets thrice daily, before meals, for the first day, followed by three or four tablets thrice daily for the next day or two, and if necessary one or two before meals for another day or two, ought to be a more satisfactory schedule for patients with severe serum sickness. Milder serum sickness should respond well to smaller doses, but in all cases it seems best to administer the majority of the tablets during the first twenty-four to forty-eight hours, continuing with diminished doses as the symptoms lessen.

SUMMARY

The administration of *histaminase*, either orally or intramuscularly, brought marked relief to twenty of twenty-two unselected patients with serum sickness, most of them with the severer forms of the disorder. Eighteen patients were treated on either the first or the second day of illness, and sixteen obtained marked relief in from eighteen to thirty-six hours. It is possible that the prophylactic use of the substance will prevent the occurrence of serum sickness in some instances and ameliorate the severity in others. The treatment appears to be rational, highly effective, safe and devoid of untoward by-effects or after-effects.

General Hospital, Cincinnati—303 Lister Building, St. Louis.

INTERMITTENT HYDRARTHROSIS WITH AN ALLERGIC BASIS

HERBERT BERGER, M.D.

TOTTENVILLE, STATEN ISLAND, N. Y.

The total number of reported instances of intermittent hydrarthrosis, including the first case described by Perrin [1] in 1845, seventy-seven collected or reported by Bierring [2] and the case presented at this time, is 106.[3]

The disease has occurred exclusively in the white race, with equal frequency in the male and the female and at an average age between 20 and 45. In some cases the condition has been familial, notably in Blanc's [4] case of a mother and daughter and the case of three sisters, a brother and a cousin reported by Schlesinger.[5] In the latter case there was also hemophilia and Quincke's edema in the family, and one person with hemophilia whom I have seen had irregularly recurrent serous effusions in the left wrist and right knee.

A complexity of apparently unrelated factors enters into the cause of intermittent hydrarthrosis, the most important being infection, endocrine disease and allergy. Trauma is considered by some authors, notably Krida,[6] to be an inciting agent in certain cases, but, in view of the numerous injuries that the knee joint sustains and the relative rarity of this condition, trauma is probably not a major cause.

The appearance of recurrent effusion following an infectious disease has been frequently reported, the infections including malaria,[1] rheumatic fever,[7] undulant fever [8] and lymphogranuloma.[9] Bierring [2] expressed the opinion that hydrarthrosis is an infectious disease and explained the large number of sterile cultures of synovial fluid on Poynton's statement that the microorganisms concerned in infections of the joints are commonly found in the subendothelial layer and are rarely seen in the fluid itself. Porter and Lonergan [10] reported a case in which marked amelioration of symp-

toms followed the use of autogenous vaccine prepared from the roots of several extracted infected teeth.

Among the cases in which an endocrine cause has been presented are several reported by Senator,[11] Krida,[6] Panas[12] and Rheindorf,[13] in which effusion and menstruation appeared simultaneously. The most interesting case is that reported by Rheindorf; hydrarthrosis occurred with the first menstruation. When the patient was 14½ years old the effusion and menstruation both disappeared, but they recurred several months later. Another patient treated by Rheindorf started to have effusions with each menstrual period at the age of 30. The cycle was interrupted during five pregnancies, after which the menstruation and hydrarthrosis recurred every twelve or fourteen days. The patient was eventually cured by a course of injections of estrogen. In eighteen cases reported by Schlesinger[14] there was a definite relationship between the effusions and ovarian dysfunction, evidenced by the fact that they either disappeared with the onset of the menopause or were successfully treated with ovarian extract, roentgen sterilization or placental extract. Not always, however, does the effusion disappear with the menopause, as Beveridge and Howe[15] encountered it in a 78 year old woman. Schmitza[16] cured one patient with lipoluteal substance (corpus luteum factor) to inhibit ovarian function, and Alzona[17] successfully treated a frigid man with intermittent hydrarthrosis with testicular extract. Vogl,[18] however, failed to relieve five patients with various types of endocrine therapy.

Many interruptions during pregnancy have been reported. Moore[19] described a woman who in three pregnancies was free from the condition from the third month to the termination of pregnancy. Pulawski[7] saw a pregnant woman who was free from effusions from the second month to the first postpartum period. In the seventh month of a subsequent pregnancy, during which the hydrarthrosis again temporarily disappeared, the patient miscarried and periodic hydrarthrosis was immediately reestablished. Paus[20] noted cessation of symptoms during a patient's first pregnancy and until the appearance of lactation and, six years later, during a second pregnancy and throughout lactation.

In a few cases the hydrarthrosis has seemed to be related to a disturbance in thyroid function. Ribierre[21] empirically treated two patients with thyroid extract and noted improvement. Lecene[22] too has achieved "brilliant and rapid results" with thyroid treatment.

That neuropathy is a factor in some cases has been demonstrated by improvement or complete disappearance of the cycle following hydrotherapy or psychotherapy.[23]

Finally, considerable literature has accumulated to show that intermittent hydrarthrosis is an intra-articular variation of angioneurotic edema and therefore allergic in origin.[24]

In support of this theory is offered the fact that the manifestations of allergic processes are frequently cyclic. The knee is the site of predilection because it has an especially large arteriolar circulation extraordinarily well supplied with medullated nerve fibers.[25]

In 1899 Schlesinger[26] compared the periodicity of intermittent hydrarthrosis and migraine. This is particularly interesting today in view of the fact that a form of therapy almost specific for the relief of migraine (ergotamine tartrate [gynergen] injected parenterally) has been used successfully in the treatment of intermittent hydrarthrosis.[27] In a case reported by Burchard,[28] migraine, urticaria and intermittent hydrarthrosis occurred together or separately at various times.

In the case herein reported, allergy to certain foods was apparently the cause of the hydrarthrosis, as shown by the fact that the symptoms completely cleared up after the elimination from the diet of offending allergens. Only one previous case has been reported[6] in which an allergic study was performed, and in that instance no specific allergens could be discovered.

DIAGNOSIS

Regularly recurring synovial effusion apparently without cause makes the diagnosis of intermittent hydrarthrosis obvious. In general the onset is abrupt and the cyclic recurrences appear at once. The cycle, although the interval may vary with different persons, is always the same for each individual, symptoms usually appearing every eight to thirteen days. In my case the interval was ten days and the appearance of the fluid was always preceded by stiffness of the affected joint (the left knee). In some cases anorexia and malaise accompany the effusion, but in the present instance headache and fatigue were the only concomitant complaints.

PATHOLOGY

Krummel[29] found that the aspirated fluid is an exudate containing 4 per cent of albumin and 400 cells per cubic millimeter and having a high specific gravity. As the fluid accumulates, a tap shows 27 per cent lymphocytes, 53 per cent large mononuclear cells and 27 per cent polymorphonuclear lymphocytes, with no evidence of phagocytosis. As the effusion subsides, the average count is 78 per cent lymphocytes, 2 per cent polymorphonuclear leukocytes and 15 per cent large mononuclear cells. Because these values coincide with the results of Risak's[30] studies of the cytology of effusions in traumatic arthritis, Krummel decided that the condition was due to "periodically recurring trauma of unknown type."

When Krida[6] performed a synovectomy at the height of effusion Dr. John E. MacWhorter reported on the removed specimen as follows:

The sections show that the synovial surface is arranged in the form of somewhat flattened villi. The villi are made up largely of rather recently formed granulation tissue which is characterized by many endothelial line blood spaces and young connective tissue cells of the fibroblastic type. The tissue as a whole is rather strikingly edematous. There is a diffuse and profuse infiltration with lymphocytes in the villi and in the tissue immediately below the synovial surface.

PROGNOSIS

The prognosis as regards general health is good but as regards the interruption of the effusion is poor. The condition in most of the reported cases continued indefinitely despite a wide variety of treatment. Occasionally it terminates spontaneously. Eradication of the cause, when it can be discovered, may break the cycle. The effusions disappear late in the course of arthritis because of the destruction of the synovial membrane.

TREATMENT

With so wide a divergence in theories as to cause, it might be expected that the therapeutic suggestions would be numerous. Physical therapy has proved useless. Psychotherapy[23] is occasionally valuable. Salicylates, cinchophen, quinine and related drugs have failed to break the cycle. Those forms of treatment which have been attended by some measure of success, in properly selected cases, include the use of endocrine products,[31] roentgen sterilization,[32] the injection of autogenious vaccines,[8] the use of ergotamine tartrate,[33] and the destruction of the synovial membrane by means of injected sclerosing solutions,[34] irradiation[35] or surgical measures.[36] The following case is the first instance of cure by allergic treatment:

REPORT OF A CASE

History.—A white woman aged 26, first examined Feb. 22, 1937, complained of a recurring swelling of the left knee. Her weight was 120 pounds (54 Kg.), her height 64 inches (162 cm.) and her blood pressure 120 systolic, 80 diastolic.

The patient had had numerous "colds in the nose," which appeared suddenly and disappeared with equal rapidity. They were not related to any season of the year. Her head would be "stopped up" when she swept floors or was in a smoke filled room. She had had rhus dermatitis almost every summer but no other serious or significant illness.

The mother was receiving treatment for diabetes, pernicious anemia and essential hypertension and had had sporadic attacks of bronchial asthma. The father had had one attack of precordial pain diagnosed as angina pectoris. The maternal grandmother had asthma. Two siblings were living and well.

Present Illness.—The patient first became aware of a disturbance in her left knee about one month prior to her first examination. At this time, with no apparent cause, she noted pain and stiffness. The discomfort was particularly marked over the calf. She continued her work, that of a stenographer, for the rest of the day and retired early that evening feeling that her leg would be better by morning. The next day her knee was very much swollen but somewhat less painful. She continued working, with the resolve that she would consult a physician the next day if the condition was no better. However, by the next morning the swelling began to disappear. By the evening of the third day it was no longer present. Ten days later the same series of symptoms appeared, and it continued to appear regularly at ten day intervals. The patient planned her engagements so that they would not fall on the date of the expected swelling. The only joint involved was the left knee. General symptoms such as malaise, headache and fatigue were present but not of sufficient intensity to occasion much discomfort.

The patient experienced periodic gastrointestinal upsets, with epigastric pain, nausea, flatulence, gaseous eructations and occasional colicky cramps. Certain foods did not seem to agree with her. Many fruits caused small wheals on the skin. This condition had been present for many years. There was no anorexia or melena. The history of other tracts was inconsequential.

Examination.—This gave essentially negative results aside from the examination of the left knee. The left patella was pushed forward and was easily ballotable. The fluid wave was definitely transmissible. This knee was 9 cm. greater in circumference than the right.

The synovial fluid was cloudy, with a specific gravity of 1.036 and 160 cells per cubic millimeter; a differential count done just prior to the apex of the cycle disclosed 34 per cent lymphocytes, 54 per cent large mononuclears and 12 per cent polymorphonuclears. The urine and blood were normal. X-ray examination of the knee gave normal results and of the teeth revealed one apical abscess. A series of gastrointestinal roentgenograms demonstrated marked visceroptosis. The Wassermann reaction of the blood was normal.

The diagnosis was (1) vasomotor rhinitis, (2) apical dental abscess, (3) visceroptosis and possible gastrointestinal allergy and (4) intermittent hydrarthrosis involving the left knee.

Course.—On completion of the diagnostic study it was assumed that there were present two separate conditions: (1) an allergic state, which caused the nasal and gastrointestinal symptoms, and (2) an infective process probably originating in the teeth, which was responsible for the joint manifestations. Accordingly the dead tooth was extracted, the apical abscess was drained and salicylates were administered orally. These measures, however, did not interrupt the course of the synovial effusions and did tend to aggravate considerably the gastrointestinal symptoms. Then an attempt was made to study the patient from the allergic point of view. Perhaps the intermittent hydrarthrosis, as well as the nose and stomach complaints, was a manifestation of an allergic state. A study was conducted by means of cutaneous testing, elimination diets (Rowe) and a dietary diary. Sensitivity was discovered to lamb, apples, pineapples, grapefruit, peaches (raw), tomatoes, string beans, corn, olives and grape jelly. A special diet was instituted May 15. The effusions, which had been appearing regularly, promptly disappeared. However, when the hydrarthrosis might have been expected, large wheals (Quincke's edema) appeared over the left knee, the left side of the chest and the left side of the neck. These persisted for three days. Ten days later they again erupted but were less severe and lasted only one day. After the diet was restricted the gastrointestinal symptoms diminished. For several months wheals appeared irregularly in various positions on the body, but by December 1937 even these had disappeared. There was no recurrence of the effusion. The gastrointestinal discomfort was alleviated but not entirely cured. A corrective support was ordered, the foot of the patient's bed was elevated and abdominal exercises were prescribed. The patient has been asymptomatic for the past five months. The nasal symptoms, which she felt were due to sinusitis, have disappeared.

SUMMARY AND CONCLUSIONS

A review of the incidence and etiology of intermittent hydrarthrosis gives rise to the conclusion that this symptom complex is not a disease but an articular manifestation of a variety of general and local conditions.

The case reported is the first in the literature in which the symptom complex was proved to be of allergic origin. The elimination of offending allergens from the diet not only brought about the definite improvement or cure of concomitant allergic manifestations, namely gastrointestinal disturbances and vasomotor rhinitis, but halted the intermittent hydrarthrosis and caused subsequent Quincke's edema entirely to disappear.

TUMORS OF THE SPERMATIC CORD

REPORT OF A CASE OF NEUROFIBROMA

T. L. SCHULTE, M.D.
Fellow in Urology, the Mayo Foundation
JOHN R. McDONALD, M.D.
AND
JAMES T. PRIESTLEY, M.D.
ROCHESTER, MINN.

Lésauvage [1] was the first to report and describe tumors of the spermatic cord. He contributed the first three authentic cases in 1845. Brossard [2] was the first to publish a comprehensive work on the subject. Patel and Chalier [3] collected and abstracted all the previous reports in a comprehensive study, which appeared as a series of publications. In their first article a list of tumors was given which did not correspond exactly with the tumors mentioned in the abstracts which appeared in their last four articles. Nevertheless their contribution is one of the most nearly complete, and their articles included three photographs which gave an excellent idea of the huge size that these tumors can attain. One of the photographs is of the largest tumor recorded, which was a fibroma weighing 15 Kg., reported by Rhenter and Villard.[4]

Hinman and Gibson [5] were the first to classify tumors of the spermatic cord. Their review of the literature was exceedingly thorough and they added a report of another fibroma. Rubaschow [6] compiled a list from previous reports and presented another classification, which varied slightly from that of Hinman and Gibson. MacKenzie [7] listed the cases previously reported and added a case of fibromyxosarcoma. Burr [8] again listed the cases and added reports of one fibroma and one sarcoma. Thompson [9] summarized previous reports and added the greatest number of new cases. He reported twenty-one lipomas and one each of fibroma, hemangioma, cystadenoma, fibrosarcoma and myosarcoma.

Since Thompson's report, the following tumors have been recorded: lipoma by Isnardi,[10] leiomyoma (benign) by Lapeyre and O'Daly,[11] dermoid by Delannoy and Demarez,[12] fibroma and lipoma by Podetti,[13] lipofibromyxoma and fibrosarcoma by Quinby [14] and myxofibroma by Wolbarst.[15] There was some divergence of opinion among several pathologists in Wolbarst's case concerning the possible neurogenic origin of the tumor.

Tumors of the spermatic cord are rare. To the present, including our case, 247 cases have been reported, as listed in the accompanying table. The following is presented as the only case of neurofibroma of the spermatic cord as yet recorded.

REPORT OF CASE

A man aged 49 had been injured thirty-five years previously, when a steel spike had lacerated and penetrated the right side of his scrotum. The laceration had been closed with clips and recovery had been uneventful. Six years before his admission to the clinic he had noticed a painless firm mass attached to the right testis. Three years later the mass had begun to increase in size and had caused discomfort, manifested by a heavy, dragging sensation in the right inguinal region, but still there had been no pain.

In the right side of the scrotum was found a mass larger than the fist of an adult, extending superiorly to just past

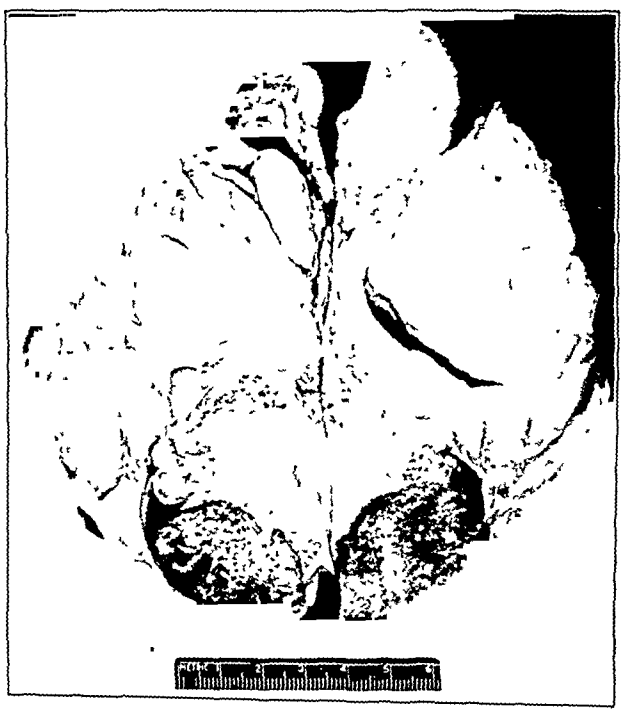

Fig. 1.—Neurofibroma of the epididymis and spermatic cord. The multilobular nature of the tumor is evident. The testis is not involved.

the external inguinal ring, in the inguinal canal. It was hard, irregular and slightly tender but a normal, soft right testis was easily palpable below it. The mass was not translucent. On the left side of the scrotum was a spermatocele about a third the size of the original mass.

From the Section on Surgical Pathology (Dr. McDonald) and the Division of Surgery (Dr. Priestley), the Mayo Clinic.

15. Wolbarst, A. L.: Myxofibroma of the Spermatic Cord, Possibly Neurogenic. Report of a Case, J. A. M. A. **109**: 1623-1625 (Nov. 13) 1937.

An orchidectomy on the right was performed, and at the same time the large irregular mass in the right side of the scrotum was completely excised. After the scrotum was opened it appeared as though the lesion arose from the spermatic cord, because the testis itself was not grossly involved. It was impossible to preserve the testis, however, as excision of the mass necessitated ligation of the vessels of the spermatic cord. This was done just below the level of the external inguinal ring. The tumor did not appear to be malignant.

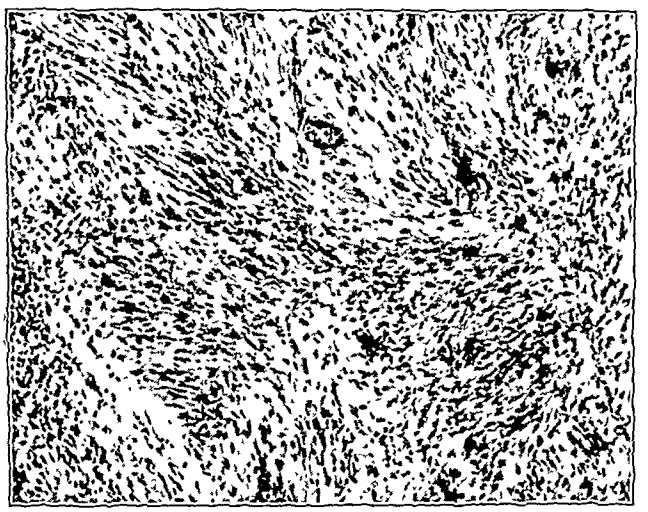

Fig. 2.—Neurofibroma of the epididymis and spermatic cord. There is a suggestion of palisading. (Hematoxylin and eosin stain; reduced from a photomicrograph with a magnification of 95 diameters.)

The specimen weighed 370 Gm. On cut section (fig. 1) a white tumor measuring 13 by 10 by 8 cm. was found attached to the epididymis, the mediastinum, testis and 11.5 cm. of the spermatic cord. It consisted of connected lobules of varying size. A small portion of the spermatic cord proximal to the tumor was attached to the mass but was not otherwise involved in the process. The testis appeared to be normal.

Microscopically (fig. 2) the tumor was seen to be composed of spindle cells and a loose meshwork of intercellular fibrils. These fibrils were stained a faint pink by van Gieson's method, showing the presence of young collagen fibrils. Some portions of the tumor were more cellular than others. An occasional mitotic figure could be demonstrated. In places there was a suggestion of palisading. In some portions the intercellular substance was basophilic, resembling in this respect the neuroglial tissue of the brain. Neurofibrils were not present, since there was no precipitation of silver by either Bielschowsky's or Orlandi's method. The absence of neurofibrils does not eliminate the possibility of neurogenic tumor, because neurofibromas arise from the sheath of Schwann; consequently they usually do not contain neurofibrils. Furthermore, it is not infrequent for neurofibromas to contain collagen fibrils. The histologic diagnosis of neurofibroma was confirmed by Dr. A. C. Broders.

Tumors of the Spermatic Cord Reported in the Literature, Including the Present Case of Neurofibroma

Benign		Malignant	
Lipoma	90	Fibrosarcoma	15
Fibroma	34	Leiomyosarcoma	2
Leiomyoma	3	Rhabdomyosarcoma	2
Myoma	4	Sarcoma	39
Dermoid	14	Reticulosarcoma	1
Teratoma	1	Lymphosarcoma	1
Lymphangioma	5	Myxochondrosarcoma	2
Hemangioma	4	Carcinoma	3
Myxoma	1		65
Myxofibroma (possibly neurogenic)	1		
Neurofibroma	1		
Cystadenoma	1	Unclassified	6
	159	Other mesodermal tumors	17
		Total tumors	247

Benign tumors, approximately ..... 71 per cent
Malignant tumors, approximately ..... 29 per cent

SUMMARY

Two hundred and forty-seven tumors of the spermatic cord have been reported; of these approximately 70 per cent were benign and 30 per cent malignant. The tumors found most frequently were lipomas, and then, in decreasing frequency, were sarcomas including fibrosarcomas, fibromas, mesodermal tumors, dermoids, angiomas and myomas. In our case a neurofibroma of the spermatic cord and testis was removed thirty-five years after a lacerating and penetrating injury of the scrotum. This is the first case of neurofibroma of the spermatic cord to be reported so far as we know.

LIPOID PNEUMONIA

REPORT OF A CASE

ANNA M. YOUNG, M.D.
H. S. APPLEBAUM, M.D.
AND
P. B. WASSERMAN, M.D.
CLEVELAND

Lipoid pneumonia (referred to by various authors as oil pneumonia, oil aspiration pneumonia, oil inspiration pneumonia, paraffinoma, paraffin oil tumor and pneumonolipoidosis) occurs most commonly in infants and in the debilitated old, resulting most frequently from the administration of laxative oils or the therapeutic instillation of oils into the nasopharynx with subsequent aspiration of the oily or fatty substance into the lung. Less frequently this lesion has been reported in adults not necessarily debilitated. The lesion was first described by Laughlen[1] in 1925 in one infant, two children and one adult. Pinkerton[2] in 1927 reported six cases in infants and children and the following year[3] reported the results of intratracheal injection of vegetable, animal and mineral oil in rabbits and dogs. The human cases, 106 in number, reported up to April 1936, are reviewed by Ikeda.[4] He adds five cases of his own. More recently[5] there have been four additional reports referring to cases of lipoid pneumonia. The aspiration of animal fats (milk, cod liver oil) is the most frequent cause in infants and children, while the adult type of lipoid pneumonia is practically limited to mineral oil and its medicated forms. According to Ikeda the infantile type is characterized by interstitial proliferative inflammation not infrequently combined with exudative pneumonia which may be due to chemical irritation alone, and the adult type by organized and granulomatous lesions. A better classification based on the nature of the irritant would be (1) animal oil or animal fat type, (2) mineral oil type and (3) mixed type.

The case reported here is one of the adult type of lipoid pneumonia following repeated aspirations of

animal oil, probably cod liver oil taken by mouth. In addition to the conditions found in the lungs by others, metastatic deposits of lipoid material were observed, principally in the kidneys and spleen, together with an associated necrotizing arteritis and periarteritis. In the kidneys the lesion was most striking and was associated with a diffuse glomerular nephritis, apparently a contributory cause of death of the patient. As in

Fig. 1.—Right lung, showing a large area of lipoid pneumonia (red and gray hepatization).

some of the cases reported by others, both clinically and on gross inspection at autopsy, certain of the pulmonary lesions suggested metastatic carcinoma.

REPORT OF CASE

History.—A white woman aged 42 suffered from an infection of the upper respiratory tract in May 1933. X-ray examination at that time showed no pathologic changes in the lungs. The patient was first admitted to Mount Sinai Hospital in July 1934 with a complaint of a painless mass in the left breast which she had noticed three months prior to admission. A radical mastectomy was performed at this time. The surgical pathologic diagnosis was comedo duct carcinoma of the breast, 2.5 cm. in diameter without metastases to the axillary lymph nodes. She had an uneventful postoperative recovery.

About the first of September 1937 pain developed in the left side of the chest and the patient consulted her surgeon for fear of a possible recurrence of the malignant condition. She was admitted again to Mount Sinai Hospital October 10, with the complaint of cough and fever of two weeks' duration.

September 26 acute pain developed in the left side of the chest with cough and expectoration of a small amount of rusty sputum. Since that time she had had fever, weakness, anorexia, malaise and a mild cough productive of about 1 ounce (30 cc.) of mucoid sputum daily. Subsequent to the patient's death it was learned from her husband that for the preceding few months she had tired more easily than formerly, had a mild cough and was short of breath and that she had taken liquid petrolatum as a laxative for three or four years and two pint bottles of cod liver oil the year previous to her death.

Examination.—October 10 the left lung field was dull to percussion below the scapular angle posteriorly. Coarse breath sounds, bronchovesicular in character with soft crepitant rales, were heard. The right lung field was clear. Except for the scar of the previous mastectomy, and conditions in the lung, physical examination was essentially negative. The patient had a moderate elevation of temperature and cough with very little expectoration. The signs of pneumonia slowly and steadily progressed. The right lung soon became involved. Chills and sweats were frequent. There was increasing dyspnea and cyanosis, and the patient became progressively more lethargic. The sputum became blood stained and two days before her death was of the nature of frank hemoptysis. The temperature continually fluctuated between 100 and 103 F., the pulse between 100 and 110. The course was progressively downhill and the patient died November 3 with signs of pulmonary edema.

The sputum on repeated examination showed no acid-fast organisms, spirochetes or pneumococci. Examination of the urine and blood chemistry determinations performed on admission to the hospital showed nothing abnormal. The white blood cell count on admission was 10,200; one week later it was 15,300 and four days later 17,400 per cubic millimeter. The blood cultures were negative. X-ray examination October 10 revealed a large area of dense infiltration extending from the fourth to the seventh rib posteriorly, with no definite cavitation. The lung fields otherwise were clear. It was the impression that there was pneumonia of the superior division of the left lower lobe. The second x-ray examination, October 22, showed that infiltration in the base of the left upper lobe had increased somewhat in amount and extent, although the apex was still clear. There was moderate infiltration of the base of the right upper lobe. The lateral view showed that the infiltration was anterior. No definite cavity could be made out.

The clinical impression at the time of death was bronchopneumonia with possible metastases to the lung from the primary comedo duct carcinoma of the breast removed three years previously.

The pertinent observations made at autopsy were as follows: The patient was well developed and fairly well nourished. The left breast was absent. There were no nodules in the old surgical scar or in the axilla. The lungs presented a striking picture. All lobes were more voluminous than the average. The right lung (fig. 1) was in great part consolidated; in places it was dark red suggesting hemorrhage, recent infarction or red hepatization; in other areas there was consolidation suggesting gray hepatization. The lesions in the left lung were of a very different character. In the lower lobe there was a roughly circumscribed firm area about 10 cm. in diameter (fig. 2). Here the tissue was gray with areas of yellow flecking suggesting areas of necrosis. The normal markings of the lung were still recognizable. In the same lobe there was a small hard circumscribed nodule about 2 cm. in diameter which was elevated above the general surface level. The normal lung markings were not recognizable here. The lesion grossly suggested metastatic carcinoma. The hilar lymph nodes were slightly enlarged, were fleshy in consistency and showed no evidence of tumor metastases.

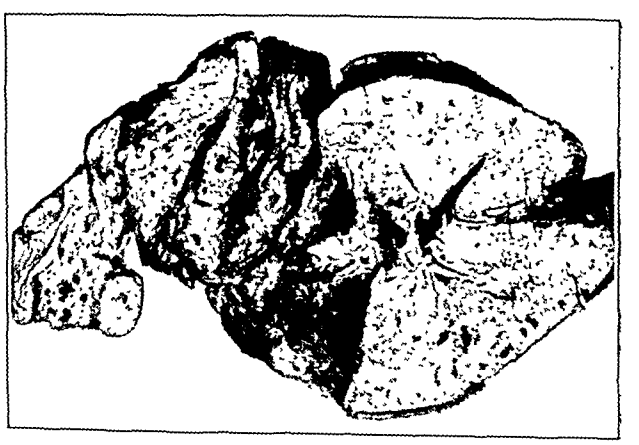

Fig. 2.—Left lung, showing areas of lipoid pneumonia, the smaller suggesting a metastatic carcinomatous nodule.

The lungs on microscopic examination showed a variety of changes of early to late lesions. In the recently involved areas there was extensive parenchymatous hemorrhage. In places there was some fibrin deposit. In quite a number of alveoli also there were a few macrophages containing small globules of oil. Elsewhere there were a few extracellular oil droplets. In the areas which grossly suggested gray hepatization the

alveoli contained many pus cells and occasional macrophages and a moderate amount of fibrin deposit. The changes microscopically were indistinguishable from those of bacterial pneumonia (fig. 3). Careful examination of Gram-stained sections of these areas showed no observable bacteria. Frozen sections stained with scarlet red showed abundant finely emulsified orange stained lipoid material especially within the alveolar walls and at the regional alveolar border. Other sections showed an intervening stage with many macrophages and a considerable infiltration by fibroblasts. These areas stained with scarlet red showed many lipoid granules within macrophages and regional to fibroblasts. The portions which in the gross specimen were firm and gray with flecking and those which grossly suggested metastatic tumor tissue histologically appeared to be fully developed granulomatous lesions with central necrosis, macrophages and fibroblasts and at the periphery scattered multinucleated giant cells of foreign body type (fig. 4). Sections of these areas stained with scarlet red showed abundant lipoid material within giant cells and macrophages and also in extracellular locations. Preparations stained with osmic acid also showed the stained lipoid material. Scrapings from these areas of the lungs treated with a saponification reagent (equal parts of concentrated ammonium hydroxide and 50 per cent sodium hydroxide) showed saponification of the lipoid material. Sections stained by the Ziehl-Neelsen method showed no observable bacilli.

The kidneys together weighed 410 Gm. The capsules stripped with some difficulty, exposing a stippled red surface with a "flea bitten" appearance. On section the cortex was swollen; the striations appeared blurred. There were numerous red flecks in the cortex. Grossly the lesion in the kidney suggested a subacute glomerular nephritis.

Microscopically the most striking changes in the kidney were in the small arteries (fig. 5). There were marked degenerative and necrotic changes of the vessel walls with a considerable infiltration of polymorphonuclear neutrophils and of lymphocytes in the vessel walls and in perivascular location resembling the picture in periarteritis nodosa. The finely granular orange

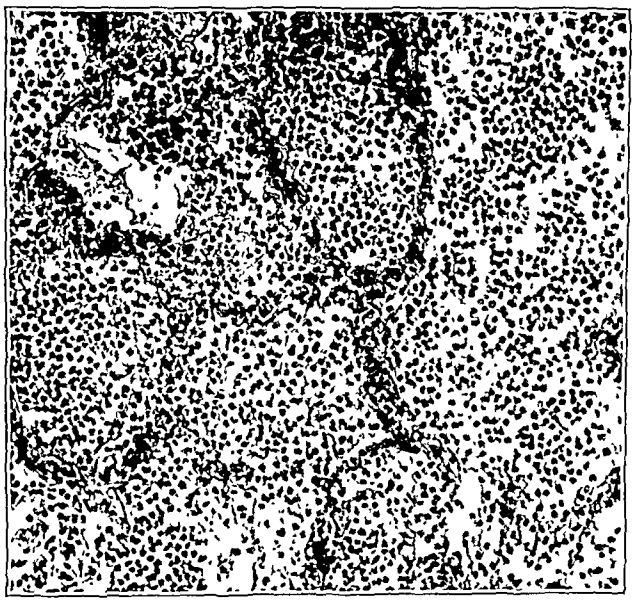

Fig. 3.—Section of right lung under low magnification showing exudative reaction of relatively recent lipoid pneumonia (hematoxylin and eosin stain). Adjacent sections stained by Gram method show no organisms; frozen sections from regional tissue stained with scarlet red show numerous small globules of oil.

stained lipoid material was especially abundant in the vessels of the glomerular tufts in the frozen section (fig. 6). This lipoid material also stained with osmotic acid. In the hematoxylin-eosin stained sections the majority of the glomeruli showed degenerative changes of varying degree, including complete necrosis and considerable round cell infiltration. There were adhesions between the glomerular tufts and between the tufts and capsule. The renal tubules were dilated; some were filled with red blood cells. There was also orange stained lipoid material within the lumens of some of the tubules. In addition, the tubular epithelium in many places showed orange stained lipoid material in the cytoplasm toward the basement membrane of the cells characteristic of fatty degeneration.

The spleen weighed 210 Gm. On section the tissue was coherent, with an increase in the red and gray elements. Microscopically, sections of the spleen also showed necrotizing

Fig. 4.—Section of left lung (hematoxylin and eosin stained under low magnification) showing granulomatous inflammation in old lipoid pneumonia (necrosis, fibrosis and marked giant cell reaction). (Intracellular and extracellular oil droplets are abundant in frozen sections of tissue from this area stained with scarlet red.)

lesions in the walls of small arteries with a considerable infiltration of polymorphonuclear leukocytes, many of which were fragmented. Sections stained with scarlet red and with osmic acid showed scattered fine lipoid droplets in the wall and in the lumen of the affected vessels.

Microscopically similar vascular lesions were present in the capsule of the adrenal and in the ovaries. In the hilar lymph nodes of the lungs intracellular lipoid droplets were present. The only other interesting microscopic observation was the presence of numerous mitotic figures in the parenchymatous cells of the liver.

The anatomic diagnosis was lipoid pneumonia involving all lobes of the lungs; metastatic lipoid deposits in the blood vessels and perivascular areas with regional acute and organizing inflammation of the lungs, kidneys, spleen, adrenals and ovaries, and hilar lymph nodes of the lungs; cloudy swelling and fatty change of the parenchymatous organs most marked in the liver; chronic cholecystitis (slight); cholelithiasis; hemangiomas of the liver, the largest 5 cm. in diameter; healed surgical incision for radical mastectomy for comedo duct carcinoma of the breast 2.5 cm. in diameter, and terminal cardiac dilatation.

COMMENT

The fact that the lipoid material present in the tissues in this case, in part at least, stained with osmic acid and was saponifiable showed that it was animal fat rather than liquid petrolatum because the latter is non-saponifiable and stains with scarlet red but not with osmic acid. This agrees with the finding of Pinkerton [3] and others that animal oil and animal fat (milk, cream, cod liver oil, rabbit fat and lard oil) produce more severe lesions than do mineral oils. The case differs from the cases previously reported in that metastatic lipoid deposits were found in and about blood vessels in the kidneys, adrenals and ovaries in addition to those in the usual location in the lungs, in the hilar

lymph nodes and less frequently in the spleen. Microscopic examination of the lungs shows the aspirated lipoid material lining the alveoli and within the lumens of the capillaries in the alveolar septums. From this primary source the lipoid material apparently gained access to the circulation and produced severe vascular and perivascular lesions in the locations mentioned.

The kidneys showed the most striking involvement, and the lesions here apparently contributed to the patient's death. In the kidneys and spleen the lesions involving the medium sized arteries resembled the picture in periarteritis nodosa. The apparent cause of the change was the presence of finely emulsified lipoid material in the vasa vasorum. The similarity of this picture with that of periarteritis nodosa suggests the possibility that the latter lesion itself may be the end result of the lodgment of a variety of granular materials in the vasa vasorum of arteries.

Clinically, lipoid pneumonia represents a chronic recurrent inflammation of the upper respiratory tract with unproductive cough and pain in the chest. The periodic recurrence and exacerbation depend on repeated inhalations of the irritating oil or oils. The oil in the lung gets there by involuntary aspiration without exciting reflex inhibition when oil is taken nasally or orally for many years. Part of this oil may be expectorated and part removed by phagocytosis, but the residual portion sets up a chronic proliferative inflammation of the lung. The x-ray examination in the case reported did not show evidence of increased linear markings (fibrosis) or a perihilar shadow, which is the characteristic picture of lipoid pneumonia, but it did show a dense shadow which was interpreted as

Fig. 5.—Section of kidney under low magnification showing a small arterial lesion strongly suggestive of periarteritis nodosa. There are marked degenerattive change and necrosis of the walls, infiltration of polymorphonuclear neutrophils and lymphocytes in the wall and in perivascular locations.

ordinary pneumonia. Had the history of the ingestion of oil been obtained earlier and been associated with the history of pain in the chest, the occasional cough and the asthenia, the diagnosis might have been suspected ante mortem. This case as well as the others reported show that even a supposedly bland agent such as animal oil may be harmful if accidentally aspirated into the lungs and that the treatment of disorders of the upper respiratory tract with various medicated oils is not free from danger. An x-ray check-up in such cases over a long period of time may furnish valuable information.

SUMMARY

A case of lipoid pneumonia occurred in an otherwise healthy woman aged 46 following repeated aspiration of animal oil (probably cod liver oil) taken by mouth. In addition to the changes in the lung similar to those reported by others, metastatic deposits of lipoid material were observed in the kidney, adrenals and ovaries, together with an associated arteritis and periarteritis. The lesions in the kidneys were most striking (a diffuse glomerular nephritis) and apparently contributed to the death of the patient.

1800 East One Hundred Fifth Street.

The Discovery of Paragonimus.—About this time a lucky chance presented him with the discovery of an entirely new human parasite, and, as had happened before, it came to him in a peculiarly unrehearsed manner. One day a very self-possessed and important Chinese Mandarin entered his consulting room, and very insultingly spat on the floor at Manson's feet, ignoring completely the numerous sawdust-filled cuspidors which were arranged around the walls. Although blushing with indignation, Manson's scientific enthusiasm was satisfied by seeing that the sputum was tinged and streaked with blood, so seizing some with the forceps which he held in his hand, and placing it under the microscope, he discovered the eggs of a hitherto unknown worm, which turned out to be those of the lung fluke Paragonimus. . . . Then collecting some more of this sputum, he placed it in a glass bottle upon his desk, and added tap water. In the rush of other work, he forgot about making further observations on the eggs, until some six weeks afterward, he noticed an offensive smell that emanated from this particular bottle; he bethought himself of examining the sediment still further under the microscope before throwing it away. Once again by the most fortunate chance, he observed the small ciliated embryo, or miracidium, trying to force its way out of the egg, and manifestly also on its way to a new host. Thus was initiated the first steps of the wonderful life history of this fluke.—Power, Sir D'Arcy: British Masters of Medicine, Baltimore, William Wood & Co., 1936.

Clinical Notes, Suggestions and New Instruments

NEW SUTURE SCISSORS

MICHAEL DEBAKEY, M.D., NEW ORLEANS

There are two essential differences in the technical use of silk and of catgut suture material. With the former it is important to employ interrupted sutures throughout and desirable to sever the suture close to the knot. The significance of employing interrupted sutures is twofold: 1. Silk sutures in the presence of secondary infection may act as an irritant or foreign body, and if continuous sutures have been used the

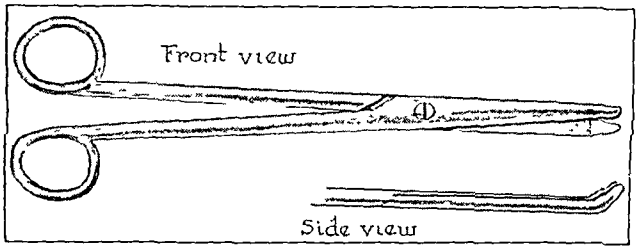

Fig. 1.—Front and side views of suture scissors; the distal ends of the blades form an angle of approximately 135 degrees.

suture produces a pathway for the further extension of this infection. The infection (particularly the chronic, relatively avirulent type) and irritant factors may produce insidiously a granulomatous type of lesion. Silk and, more recently, cotton are employed as a routine in the Tulane Surgical Service. Although at present interrupted sutures are used entirely, with no complications, continuous sutures were used very early in the adoption of the all silk technic. During this period several cases were observed in which granulomatous lesions, as described, developed. These were completely excised and the wounds closed with interrupted silk sutures without drainage and with primary healing. 2. A very fine silk can be used with relatively greater and more secure tensile strength. Because silk does not become edematous, as does catgut, the

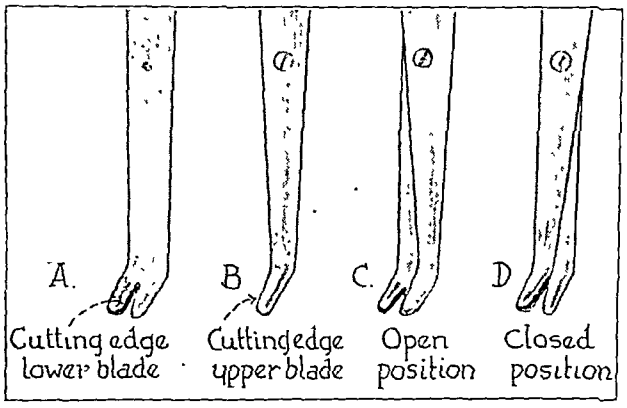

Fig. 2.—Construction of the blades: *A*, lower blade; the angled part is provided with a V-shaped opening, one side of which has a cutting edge. *B*, upper blade; the angled part of the blade has a cutting edge which opposes that of the lower blade. *C*, upper and lower blades assembled in a completely open position. *D*, upper and lower blades assembled in a completely closed position.

knot is less likely to slip. For this reason it is not only unnecessary but undesirable to cut silk sutures as long as catgut sutures. Actually the suture should be severed as close to the knot as possible. Any part of the suture distal to the knot is simply excess foreign body. Thus it becomes obvious in using an all silk technic that the cutting of sutures is an important factor. In an attempt to simplify and facilitate the performance of this technical procedure, new suture scissors have been devised.

The scissors are similar to the conventional type, differing only in construction of the blades, which form an angle of approximately 135 degrees near the distal end (fig. 1). Only the angled part of the blades has a cutting edge. The lower blade is provided with a V-shaped opening at its end, one side of which has a cutting edge (fig. 2 *A*). The upper blade has a narrowed tapering end and is provided with a cutting edge which opposes that of the lower blade (fig. 2 *B*). Thus when the two blades are assembled and in the open position the angled part of the upper blade is above the noncutting side of the lower blade (fig. 2 *C*). In this position the cutting edges of the respective blades oppose each other. A lock arrangement prevents wider opening of the blades. As the scissors are closed the upper blade moves across the V-shaped opening, the cutting edges passing each other until the completely closed position is assumed (fig. 2 *D*).

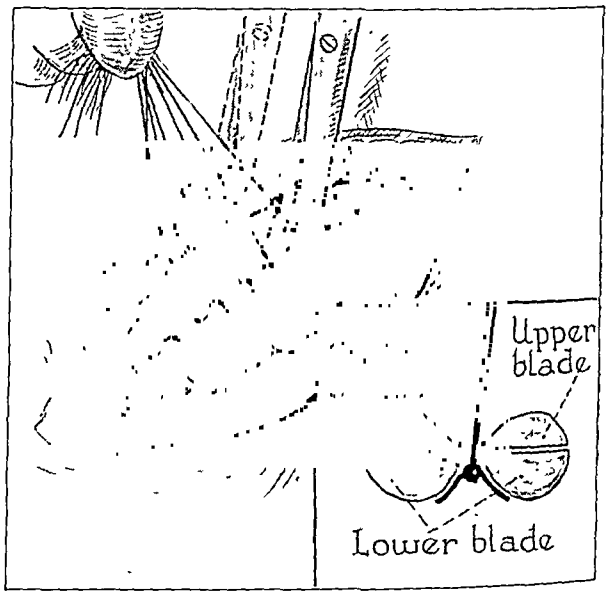

Fig. 3.—Method of operating the scissors: As the ends of the tied suture are held taut, the V-shaped end of the open scissors is brought against them so that the suture lies in the apex of the wedge, and then the scissors are slid down the suture until stopped by the knot. The inset represents diagrammatically the cross section of the upper and lower blades and the position of the suture, to show how the desired site of cutting the suture is automatically found.

The operation of the scissors is extremely simple. The ends of the tied sutures are held taut as the V-shaped end of the open scissors is brought against them so that the suture lies in the apex of the wedge (fig. 3). The scissors are then slid down the suture until they are stopped as the knot impinges against the wedge (fig. 3, inset). Thus the desired site of cutting the suture is automatically found. In this position the blades are closed and the suture is severed.

Whereas with the conventional type of suture scissors considerable practice is necessary in cutting silk sutures at the desired site, with the scissors herein described this site is quickly and automatically found even by the tyro and the time required for the proper performance of this technical procedure is diminished considerably. The angled character of the scissors permits convenience and facility in severing sutures in relatively inaccessible or deeper areas of the wound. For this purpose also the scissors are made in several lengths. Because the cutting edges are relatively small (about 0.5 cm. in length) and because of the protection afforded by the construction of the blades, the danger of inadvertently cutting tissue is minimized.

From the Department of Surgery, Tulane University of Louisiana School of Medicine.

CORPUS LUTEUM CYSTOMA

HOMER WHEFLON, M.D., AND GALE WILSON, M.D., SEATTLE

Cystic tumors of the ovary arising from the graafian follicle are common. Small cystic degenerations of the corpus luteum are not uncommon, but a single cyst of any appreciable size is very unusual, although cysts "the size of a child's head" have been described.[1] Hertzler[2] states that these cysts develop because of the failure of the luteal cells to form fibrous tissue and the resultant corpus albicans—"at any rate the luteal cysts must be due to some disturbance in the physiology of ovulation. The result is a cyst seldom larger than a walnut, usually not larger than a hazelnut. Having attained this size, they may remain unchanged and symptomless, or hemorrhages may take place in them."

REPORT OF CASE

History.—Miss R. G., a white American office worker aged 34, was perfectly healthy until February 1938, when bilateral tubal abscesses developed and drained through the vagina. There was an uneventful recovery from the pelvic infection, and in September 1938 the patient returned, complaining of insomnia, "hardiness of the abdominal muscles" and enlargement of the lower part of the abdomen. Pelvic examination at this time revealed a mass the size of a grapefruit in the left broad ligament, with the uterus small and pushed to the right. The patient stated that she first noticed the mass about a month previous to entry and that for the past several years her periods had been irregular, usually with a six to eight week interval and a three day flow, and that since February 1938 they had occurred more regularly, at a monthly interval, but with a very scanty flow.

Operation.—An operation performed by Dr. H. J. Davidson at the Columbus Hospital September 21 disclosed a large tense mass adherent to the left broad ligament, bilateral hydrosalpingitis and two small fibroids in the anterior surface of the uterus. The right ovary appeared normal. The mass, the tubes and the two small fibroids were removed. The abdomen

Fig. 1.—External surface of cyst, showing pedicle.

was closed without drainage. The wound healed by primary union and convalescence was uneventful. Menstruation began the day following operation.

Pathologic Examination.—The specimen consisted of a smooth tense grayish mass, 11 cm. in diameter, to which was attached a uterine tube measuring 9 by 3 cm. On section the dilated tubal lumen was filled with a thick viscid mixture of what appeared to be blood and pus. On section of the tumor mass, thick, bloody and purulent appearing material under marked pressure was seen to fill a cyst cavity, the walls of which were tough and fibrous, gray and about 1 cm. in average thickness. The inner lining of the cyst was bosselated and yellowish, and it stripped fairly readily from the underlying tissue. Microscopic study of the wall of the cyst revealed no true ovarian structure. The wall was thick and fibrous, with small areas of round cell infiltration. The lining showed small round cells

Fig. 2.—Cyst opened and evacuated, showing thick, bosselated, yellowish wall.

arranged more or less in strands, with a matrix of vascular fibrous tissue. There were indefinite columns of cells, not unlike normal lutein cells but interspersed with frequent signet ring shapes and many mitotic figures. There was no definite epithelial edge and no indication of invasion of the capsule.

COMMENT

The case is presented because of the rarity of a large unilocular corpus luteum cyst. The growth of this cyst was rapid; the wall was thick, and in spite of the mitotic figures and the origin from ovarian tissue the growth was benign as long as encapsulated. The hormonal effect has heretofore apparently not been recognized, but an excess of lutein hormone will cause amenorrhea (relative or complete) and the condition is readily remediable by surgical removal of the cyst.

PHOTOSENSITIZING AGENTS

A BRIEF REVIEW OF THE LITERATURE

I. LEWIS SANDLER, M.D., WASHINGTON, D. C.
Assistant Professor of Dermatology and Syphilology, Georgetown University School of Medicine

My purpose in this paper is to report two cases of pigmentation—one resulting from a photosensitizing dye and the other from a toilet water—and to discuss briefly the parenteral and ingested photosensitizing substances as well as the topical photosensitizers.

Pigmentation of the skin may follow the topical application of a number of photosensitizers, e. g. eosin and eosin compounds, oil of bergamot, oil of lavender, oil of cedar, vanillin oil, perfume, eau de cologne, mercury bichloride, dyes and Dictamnus albus (gas plant).

Substances such as sulfanilamide, gold, silver, hematoporphyrin, acriflavine, eosin, rose bengal, erythrosin (fluorescein) and chlorophyll, when injected into the body, possess the property of sensitizing the skin to light.

Photosensitization in animals has been associated with the eating of buckwheat, clover and sudan grass.

REPORT OF CASES

CASE 1.—Miss A. P., aged 30, a brunette, consulted me March 18, 1938, for three dark gray, flat, superficial, pigmented areas on her lower lip. Each area was not more than 0.5 cm. in circumference and irregular in outline and had been present since the past summer. The patient had been using one brand

of lipstick for a number of years until the past summer, at which time she changed to a different brand (Louis Philippe). I considered this pigmentation as resulting from photosensitization to one of the ingredients of this lipstick.

July 22 the patient consulted me for an irregular grayish pigmentation of the webs of the fingers of her right hand. She had recently been applying an eau de cologne (Arly) to these areas. I considered this pigmentation as resulting from one of the ingredients of this particular eau de cologne.

Perfumes are complex products; the better ones may contain as many as twenty-five ingredients and consist of (*a*) a coloring, (*b*) a fixative, (*c*) a solvent, (*d*) essential oils and (*e*) an odor —animal, vegetable or synthetic.

August 17 the patient consulted me for a linear grayish pigmentation extending from the outer surface of the left thigh to the ankle (figs. 1 and 2). The pigmentation was approximately 3 cm. at the upper part of the thigh and gradually narrowed toward the ankle. The patient noticed this pigmentation in the evening after swimming. She had worn the same bathing suit four times previously while swimming in an indoor pool but on this particular afternoon in August she decided to sun herself. After swimming in the pool she squeezed the water from the left side of the pants of the bathing suit and sat in the sun an hour, developing a mild generalized erythema. The same evening the pigmentation was noted. It had occurred where the expressed water "ran down" her thigh. When examined three months later the pigmentation was still present but fading.

The pants of the rayon bathing suit were red, while the outer part (skirt) was red with a white polka dot. Most of the red dyes used in bathing suit manufacture fall within the eosin group. In reviewing the literature I have been unable to find a case of pigmentation from a photosensitizing dye as described in this case.

I performed patch tests with various portions of the bathing suit; I wet the pants and skirt, squeezed the water out, applied the water to the skin and then exposed the area to an erythema dose of ultraviolet rays; I used chlorinated water (for chlorine was used in the pool) and repeated the tests, but with negative results. Unfortunately I could not persuade the patient to go swimming and repeat the same procedure that precipitated the pigmentation.

Since the experiment could not be reproduced by ultraviolet rays I am of the opinion that summer sunshine is necessary for this type of reaction. Goodman [1] considered three factors essential: (1) sensitivity of the person, (2) some ingredient of the perfume or substance and (3) natural summer sunlight. It should be remembered that no source of artificial light closely resembles noonday summer sunshine and that experiments performed with the artificial sunlight cannot be completely accepted as equivalent to natural noonday summer sun.

It appears that certain wavelengths of light are concerned in precipitating these photosensitizing reactions, and it is believed that the violet and ultraviolet rays of the spectrum are most important.

The patient stated that she was not unduly susceptible to the sun, and although on several occasions she had exposed herself for an hour or more, only a mild erythema had developed followed by a slight tanning.

CASE 2.—Mrs. A. S., aged 25, a brunette, was seen in consultation at Emergency Hospital in July 1935 for a slate-colored pigmentation of the face, anterior portion of the neck, the chest, the flexor surfaces of the forearms and the left leg and thigh. The patient had fractured her right leg, which had been placed in a plaster cast. The first of July the patient was permitted sunbaths on the roof of the hospital and the first few days after exposure to the sun a generalized erythema developed; several days later a discoloration of the skin appeared which became progressively more marked. The history revealed that each day before exposure to the sun the patient had applied an eau de cologne (No. 4711, manufactured by Ferd. Mulhens, Inc.) to the areas that became discolored. This discoloration disappeared in four months.

Many toilet waters, perfumes and cosmetics contain oil of bergamot, which is a definite photosensitizing agent. The application of oil of bergamot in alcohol plus ultraviolet rays will in many persons produce a dermatitis followed by pigmentation. Some authors report the production of pigment in depigmented (vitiliginous) areas following its use. In one experiment I applied (1) an eau de cologne (4711), (2) 10 per cent oil of bergamot in 70 per cent alcohol, (3) eau de cologne

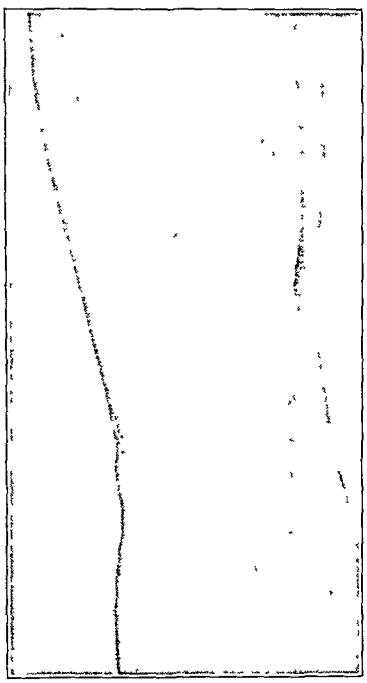

Fig 1 (case 1).—Linear pigmentation of the thigh and leg.

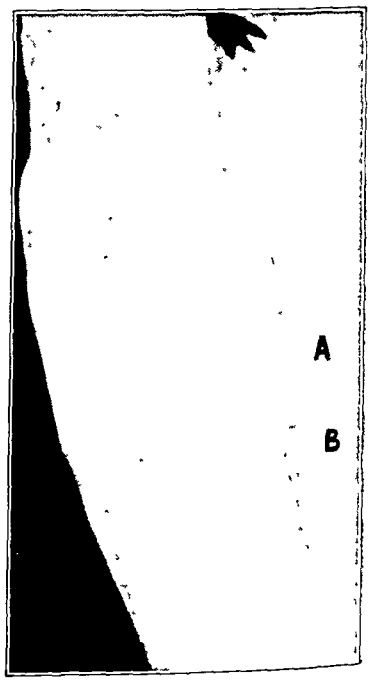

Fig 3 (case 1).—Linear (*A*) which followed application of 10 per cent oil of bergamot in 70 per cent alcohol plus ultraviolet rays and (*B*) which followed application of eau de cologne (Arly) plus ultraviolet rays

1. Goodman, Herman: Perfume Dermatitis: Case Report with a Review of the Literature and Bibliography, Brit. J. Dermat. & Syph. 43: 177 (April) 1931.

(Arly) daily to the forearm and followed by alpine ultraviolet erythema doses and on the sixth day definite pigmentation was noted at the sites of the application of oil of bergamot and eau de cologne (Arly) (fig 3).

COMMENT

Gross and Robinson[2] reported the first cases in the United States of dermatitis and pigmentation following the use of perfume. Their five patients used imported perfumes. The authors produced pigmentation, preceded by erythema, by the application of a drop of perfume followed by a suberythema dose of ultraviolet rays. "This dermatitis has definite characteristics. It is usually found in the neck and chest. . . . The shape of such an area is usually similar to that of an area covered by a small drop of flowing fluid."

Freund[3] in 1916 originally described this curious pigmentation and was successful in reproducing the pigmentation by exposure to the sun after applying eau de cologne and oil of bergamot.

Goodman[1] in 1931 reported a case of perfume dermatitis and described the pigmentation as giving the appearance of being caused by a dark colored fluid running down. The patient stroked the moist glass stopper of the perfume bottle behind her ear and down her neck. This site of pigmentation is not uncommon.

Hellier[4] reported a case of lipstick dermatitis resulting from the eosin and stated that the majority of lipsticks contain eosin.

Silver, when applied locally or ingested, may produce the characteristic slate color of argyria in the skin and adjacent mucous membrane of the exposed portions of the body.

Discoloration of the nails due to mercuric sulfide activated by rays of light has been reported by Callaway.[5]

Conspicuous pigmentation preceded by bullae and erythema has followed contact with Dictamnus albus[6] (gas plant) when exposed to the sun's rays. The toxic substance is a photosensitizer for dermatitis, and pigmentation was produced only after exposure to the sun.

Cutaneous pigmentation has followed injections of gold salts. Cardis and Conte[7] have reported chrysocyanosis in thirty-four tuberculous patients following treatment with gold salts. The pigmentation, which is persistent and occurs only on portions of the skin exposed to light, such as around the eyes, forehead, back of the hands and forearms, may not appear for two or three years.

Persistent hypersensitivity to light after intravenous injections of acriflavine hydrochloride has been reported by Haxthausen.[8] After injections of acriflavine hydrochloride, edema and erythema of her face and hands would develop when exposed to diffuse daylight and sunshine. Bright sunlight did not have any effect on the patient when the windows were shut.

Hematoporphyrin hydrochloride[9] has produced intense pigmentation at the point of injection. This pigmentation appeared on exposure to sunlight two months after the use of the drug.

Quin[10] produced sensitization to light in sheep and goats by injecting 0.5 Gm. of hematoporphyrin intravenously and exposing them to direct sunlight. Ten minutes after exposure to sunlight there was pruritus followed by edematous swelling of the ears and face, dry gangrene and finally opacity of the cornea with blindness.

Jodlbauer and Busck[11] produced the same reactions by injecting eosin, fluorescein, erythrosin and rose bengal into rabbits, rats, mice and guinea pigs and exposing the animals to direct sunlight.

Meyer-Betz[12] received an intravenous injection of hematoporphyrin and when he was exposed to direct sunlight of short duration there resulted pronounced edema of the hands and face followed by superficial necrosis in a few areas.

Photosensitization in animals has followed the ingestion of certain substances. Hertwig[13] in 1833 observed fagopyrism (buckwheat poisoning) in a herd of swine, associated with the eating of buckwheat and exposure to direct sunlight.

Trifolosis, or clover disease, and similarly photosensitization from Sudan grass have been reported.[14]

Sulfanilamide is also a photosensitizing agent. Brusting[15] and Neuman and Sharlit[16] have discussed this peculiar property. The outstanding characteristic was its limitation to the regions of the skin which had been exposed to direct sunlight. The skin became erythematous, edematous and urticarial. The presence of certain concentrations of sulfanilamide in the skin of susceptible persons may produce a state of photosensitivity, and therefore patients receiving this drug should be shielded from direct exposure to the sun or to ultraviolet rays.

Abnormal hypersensitivity to light is a determining factor of several cutaneous diseases, particularly hydroa aestivale, eczema solare, xeroderma pigmentosum, lupus erythematosus and pellagra. Hydroa aestivale[17] has been accepted as a photodynamic phenomenon in which hematoporphyrin acts as a sensitizer.

Recently avitaminosis in relationship to pigmentation has received serious consideration. Smith and Ruffin,[18] by keeping pellagrins on a deficient diet, has succeeded in causing the dermatitis to reappear in thirteen of thirty-five patients by exposing them to the sun. Hoff[19] has found that many pathologic pigmentations of the skin are due to a deficiency of vitamin C. Cornbleet[20] states that the clinical condition of increased pigmentation occurring in scurvy is quickly eradicated by administration of vitamin C, while hyperpigmentation in Addison's disease is reduced to normal by the administration of vitamin C.

In the light of these facts it is possible that patients in whom pigmentation develops after exposure to sunlight may have an absence or diminution of certain vitamins, particularly vitamin A or C or both.

Very little is known of the mechanism of sensitiveness to light. Ellinger[21] worked out a method for studying the problem of the relationship between light sensitivity and cutaneous capillarization by determining the number of visible capillaries per unit of surface and concluded that in many cases of high degree of sensitivity to light he found an increase in the number of capillaries of the skin.

A TUBE FOR USE IN THE POSTOPERATIVE CARE OF GASTRO-ENTEROSTOMY PATIENTS—A CORRECTION

W. OSLER ABBOTT, M.D.
Associate in Medicine and F. M. Kirby Fellow in Surgical Physiology, University of Pennsylvania School of Medicine
AND
ARTHUR J. RAWSON, M.E.
Associate in Medical Physics
PHILADELPHIA

In the May 29, 1937, issue of THE JOURNAL a tube was described for use in the postoperative care of patients undergoing gastric operations. It had the twofold function of keeping the stomach constantly empty and yet of allowing jejunal feeding at regular intervals. This was accomplished by the insertion into a duodenal tube of a silver outlet valve at the tip for jejunal feeding and of a silver inlet valve 30 cm. proximal to the tip for the aspiration of the contents of the stomach. Although a large double lumen tube had once been used for the same purpose it was felt that the use of a single tube with valves was preferable because of the larger lumen that would be obtained for a given outside diameter.

In the light of subsequent experience this proves to have been an error. Though the standard 16 F. duodenal tube has a lumen which is 7 sq. mm. in cross section as compared with 4 sq. mm. for the larger lumen of our 16 F. double lumen tube, it is the latter which is less easily occluded by mucus and blood clots. This is because the lumen of the two lumen tube has a flat side (fig. 2) which sags when suction is applied and bulges in response to pressure. The wide changes in the

cross sectional area thus produced allow one to dislodge a mucous plug very readily by injecting water with a syringe, while the practically fixed cross sectional area of the round lumen tube, though actually larger, greatly reduces the chance of clearing the passage once it has become occluded. In addition, the valves proved too difficult to keep in order for practical purposes.

From the Gastro-Intestinal Section (Kinsey-Thomas Foundation) of the Medical Clinic and the Johnson Foundation of Medical Physics, Hospital of the University of Pennsylvania.

For these reasons we have abandoned the use of the valved single lumen tubes and now rely entirely on a double lumen tube to accomplish the purpose originally described. The tube (fig. 1) is introduced through the nose, the end drawn out at the mouth and a Lyon duodenal bucket attached. The patient then swallows the tube to the first mark, which is placed 75 cm. above the tip. This permits the portion of the tube in the stomach to be slack and the aspirating holes to lie within the cardia. When a gastro-enterostomy is then performed the surgeon on completion of the anastomosis slips the tip of the tube through the stoma and for 30 cm. down into the distal portion of the jejunal loop with his thumb and fingers. The tube meanwhile is advanced through the nose until the second mark (85 cm.) reaches the external nares, and it is retained in that position. Not less than six hours after operation, nutrient solutions may be injected through the smaller lumen into the jejunum, while to the larger lumen of the tube constant suction may be applied to draw off the gastric contents.

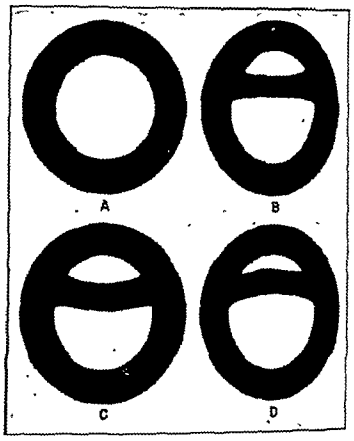

Fig. 2.—Cross sections of single and double lumen tubes: *A*, the proportion of inside to outside diameter of a 16 F. tube; *B*, the position of the septum in a 16 F. double lumen tube; *C*, the degree to which the septum sags when a negative pressure of 150 cm. of water is applied to the larger lumen; *D*, the degree of bulge occurring when water is injected with a syringe.

Either type of tube gives one the ability to feed a partially starved patient, even on the day of operation, by a means that is more physiologic than is intravenous infusion, but the flat sided lumen and the lack of moving parts makes the double lumen tube unquestionably the better one for the purpose.

A NOTE ON THE USE OF VITAMIN B_6 IN HUMAN NUTRITION

TOM D. SPIES, M.D.
WILLIAM B. BEAN, M.D.
AND
WILLIAM F. ASHE, M.D.
BIRMINGHAM, ALA.

Since vitamin B_6 (2-methyl, 3-hydroxy, 4,5-di-[hydroxymethyl] pyridine), one of the water-soluble compounds of the vitamin B complex, is a component of yeast and of liver extract, both of which are effective antipellagric substances, it was thought that perhaps this vitamin also might be important in human nutrition. Clinical studies of the effect of vitamin B_6 on nutritional deficiency diseases were made possible by the recent synthesis [1] of this substance.

We [2] described recently the study of a large series of undernourished persons who had clinical evidence of pellagra and beriberi and certain symptoms which are corrected by the administration of riboflavin. Such persons are greatly benefited by the addition of nicotinic acid, thiamin chloride and riboflavin as supplements to their usual inadequate diets. Some of them regain sufficient strength to return to work, thus enabling them to afford a better diet and thereby be restored to good health. Those whose diets remain unchanged develop symptoms which are not corrected by the addition of these synthetic chemical

substances. Such symptoms include extreme nervousness, insomnia, irritability, abdominal pain, weakness and difficulty in walking.

Four persons who had been treated successfully for pellagra and beriberi, but who remained on their deficient diets and were now complaining of these symptoms, were selected for study. Within four hours after the administration of 50 mg. of pure synthetic vitamin B_6[3] in sterile physiologic solution of sodium chloride, all patients experienced dramatic relief of these symptoms and increased strength. Within twenty-four hours these symptoms had disappeared. One of these persons who had been unable to walk more than a few steps walked 2 miles within twenty-four hours after the injection of 50 mg. of vitamin B_6.

These observations indicate that vitamin B_6 is important in human nutrition and support the hypothesis that the deficiency diseases are often multiple in nature.

Special Article

CONFERENCES ON THERAPY

EVALUATION OF DRUGS USED IN THE TREATMENT OF SYPHILIS

NOTE.—These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.

DR. JANET TRAVELL: The drugs with specific curative effects in syphilis are the compounds of arsenic, bismuth and mercury. Some of the questions relating to their use, on which syphilologists do not all agree at present, are: Which metal to use at any given stage of the disease? What preparation of the metal to select? How much of it to give? By what route? What plan of treatment to follow, whether continuous or interrupted or combined, and so on? And if toxic reactions or resistance to therapy develops, what other course to follow? If no reactions develop, when to stop treatment?

What are the objectives of antisyphilitic therapy? This is one instance in which therapy is aimed directly at the cause of the disease. So the goal is the complete cure of the disease. Treatment should accomplish a rapid disappearance of the spirochete from the mucocutaneous lesions in order to prevent contagion and to prevent the spread of the infection to organs commonly involved in late syphilis. Second, in chronic or late syphilis treatment should effect an arrest of the various pathologic changes which have already taken place. Third, whatever the stage of the disease, a permanent cure should be effected with complete sterilization of the patient with respect to the spirochete. Finally, treatment should not cause injury to the tissues of the host. Elimination of reactions is an important phase of the problem of therapy.

What methods are used for comparing the relative therapeutic potency or efficiency of specific antisyphilitic drugs and of their numerous preparations and of the various plans of administration?

First, there are in vitro experiments measuring directly the effect of the drugs on spirochetes and trypanosomes which are susceptible to the action of these metals. The in vitro experiments do not yield any decisive information regarding effectiveness in man because the arsenobenzenes (except mapharsen) and the complex organic derivatives of bismuth and mercury do not exert a prompt spirocheticidal action in vitro in the low concentrations which are comparable to those obtaining in the body after their administration. Some spirocheticidal action may be noted in low concentrations, but only after considerable periods of time have elapsed during which it may be shown that decomposition products of the compound may have been formed, as for instance arsenoxide from the arsphenamines. The mode of action on the spirochetes is not known but it is likely that it is not due to a direct spirocheticidal action of the complex molecule itself. It is rather due to some decomposition product found in the body and circulating in the blood stream in low concentration exerting its effect over a prolonged period of time. The in vitro experiments do not take into account the role played by the tissues of the host, and for this reason they are not a satisfactory means of comparing efficiency in the treatment of syphilis.

As for the animal experiments used for measuring the curative action of drugs in experimental syphilis: Syphilis has been transferred to the mouse, the rabbit, the monkey and the chimpanzee. The trouble is that in none of these species does the spirochete produce the pathologic lesions which are characteristic of late syphilis in man. In mice this organism produces an innocuous symptomless infection without pathologic lesions of any sort. The mouse, however, harbors the organisms, which may be recovered from the brain as long as about a year and a half after infection, a long time in the life of a mouse, without their having produced any symptoms or any apparent pathologic changes in the brain. In experimental syphilis in the rabbit, inoculation with the spirochete produces a primary lesion followed by secondary generalized involvement of the testis, lymph nodes, skin, eye and bone. But again no pathologic lesions are noted in the liver or other viscera or in the central nervous system, nor does the pregnant rabbit transmit syphilis to the fetus in utero. In view of the fact that preparations are frequently judged by their effects in rabbit syphilis, the extreme variability of its course under very slightly different experimental conditions is important. In some rabbits a symptomless infection similar to that seen in mice may even be produced, and these variations may be responsible for some of the conflicting reports in the literature. In monkeys and apes the disease is similar to that in rabbits. In all these species, infection, even when symptomless, usually persists for the life of the animal unless treatment is given.

All of this means that animals may be used to evaluate drugs with respect to a limited number of our objectives. They may be used to study the rapidity of disappearance of the spirochete and the rate of regression of lesions in early syphilis and also to some extent to study toxicity. On the other hand, the permanent curative action or effectiveness in preventing the vascular and hepatic and nervous system lesions of late syphilis and the healing action on these already developed lesions cannot now be studied in animals but only in man, in carefully mapped out long range studies extending over a period of several years in order to be 100 per cent sure that a permanent cure has actually been obtained.

Regarding the experiments in man, several criteria are used in judging the therapeutic efficiency of a compound: First the symptomatology, or the clinical course

[3] Furnished through the courtesy of Merck and Company, Rahway, N. J.

of the disease. Second the serologic reaction, especially of the blood and spinal fluid. Third the daily urinary excretion of the metal in the case of bismuth and mercury. The basis for this last is that the amount of metal appearing in the urine is believed proportional to the amount of metal circulating in the blood stream. Since the circulating metal rather than that stored in the tissues is responsible for its therapeutic effects, urinary excretion serves indirectly as an index of therapeutic efficiency. That is the theory. Urinary excretion has been widely studied with this in view. Sollmann and his co-workers found that, when the amount of mercury in the urine after four weeks of treatment approached 1 mg. a day, minor toxic symptoms appeared, salivation, stomatitis and albuminuria. When the amount of mercury approached 2 mg. a day signs of more severe poisoning resulted, and all forms of treatment which yielded less than 0.5 mg. a day of mercury in the urine after four weeks of administration were found to be clinically ineffective in early syphilis. Bismuth is less toxic than mercury and Sollmann found that the amount of bismuth in the urine must be maintained at a minimum of about 3 mg. a day to obtain satisfactory effects in early syphilis.

At present it is generally believed that better results are obtained when there is a continuous low level of excretion of the metal in the urine, as produced by the injection of insoluble or slowly absorbed salts, than when high peaks of concentration for a short period of time are produced, as after injection of the more soluble and rapidly absorbed compounds. Sollmann has recently recommended the simultaneous use of a soluble and an insoluble salt of bismuth at the beginning of treatment with the idea of producing promptly an initial high peak while at the same time building up more slowly the lower concentration. Such high peaks of concentration in the urine can be maintained for only short periods of course without producing toxic symptoms. The significance of figures on urinary excretion has rather limited practical application, however. Urinary excretion does not directly measure any single factor but rather it represents a composite of several factors, such as the rate of absorption of the metal, the rate of release from the depots in the body, the rate of elimination by the kidneys, and I wonder whether it is in all instances a faithful measure of clinical efficiency.

Is arsphenamine really more effective than neoarsphenamine, as is commonly stated in the textbooks? There is no way to obtain an answer to this question except by testing their relative efficiency in man, and the conclusions as to the superiority of arsphenamine over neoarsphenamine are based largely on the results of the American Cooperative Clinical Group. They studied a series of about 2,500 patients treated with arsphenamine in five clinics and a series of 355 cases of neoarsphenamine treated by private practitioners before the patients were admitted to the clinics. Various plans of treatment were used in conjunction with both the heavy metals. When the results were broken down according to the plan of treatment, it was found that with the so-called continuous method ultimately satisfactory results were obtained after arsphenamine in about 36 per cent of the cases and after neoarsphenamine in about 20 per cent, and that relapses occurred in about 12 per cent after arsphenamine and in 16 per cent after neoarsphenamine. These are the figures that are commonly quoted in favor of the superiority of arsphenamine, and I might say that in splitting up the whole series the total number of cases treated by the continuous method was 550 for arsphenamine and only 79 for neoarsphenamine. When all schemes of treatment were grouped together it was found that ultimately satisfactory results were obtained in 21 per cent of the cases after arsphenamine and 18 per cent after neoarsphenamine, that relapses occurred in 27 per cent after arsphenamine and 27 per cent after neoarsphenamine and that a reversal of the Wassermann reaction was secured in 76 per cent after arsphenamine as compared with 71 per cent after neoarsphenamine. When the two drugs were examined for serious reactions it was found that 22 per cent of the cases showed serious reactions after arsphenamine and only 13 per cent after neoarsphenamine. It should be noted, however, that ultimately there were one and one half times as many Wassermann fast cases in the neoarsphenamine treated as in the arsphenamine treated group. These statistics do not seem to show any tremendous superiority of arsphenamine over neoarsphenamine. The Cooperative Clinical Group also adds that, since the neoarsphenamine was given under the care of the private physician, treatment was presumably more irregular than in the clinic, and "the less favorable conditions under which neoarsphenamine has been administered should be taken into account in comparing the results."

I want to call attention to the relative dosage of these two compounds. The usual doses of arsphenamine are about two thirds those of neoarsphenamine. Doses of 0.6 Gm. of arsphenamine and 0.9 Gm. of neoarsphenamine are said to be equivalent because the arsenic content is approximately the same in the two instances. On the other hand, the arsenic content is only one factor which determines therapeutic efficiency and there are many other factors, such as the solubility of the compound, the rate of penetration into the tissues, the rate of decomposition in the body and the rate of elimination from the body. The arsenic content may actually be one of the less important factors. For instance, the dose of mapharsen is 0.06 Gm., which contains 0.017 Gm. of arsenic; the customary dose of arsphenamine, 0.6 Gm., contains 0.19 Gm. of arsenic, or approximately ten times as much, and yet these doses have been found in experimental syphilis to be equivalent in therapeutic potency; in the case of tryparsamide, I might add, the usual dose, 3 Gm., contains 0.75 Gm. of arsenic in pentavalent form and in spite of the much larger arsenic content this compound is relatively ineffective in the treatment of early syphilis. The latest bulletin of the U. S. Public Health Service on syphilis (No. 6) recommends that 0.1 Gm. of arsphenamine be given for each 0.2 Gm. of neoarsphenamine, a ratio of 1:2 instead of 2:3. If these relative amounts are used it may very well be that neoarsphenamine will prove to be at least as effective as arsphenamine.

In the Oslo clinic from the years 1891 to 1910 prior to the introduction of arsphenamine it was not believed worth while to treat patients with syphilis. The clinic had a fairly large control series of 309 untreated patients, who were alive and reexamined from ten to twenty years after the primary infection, and these may be compared with the similar group of treated patients of the Cooperative Clinical Group observed for a corresponding period. It is interesting that from ten to twenty years after infection in the untreated group 50 per cent were symptom free, 36 per cent with a negative Wassermann reaction and 14 per cent with a positive Wassermann reaction, and of the treated

patients of the Cooperative Clinical Group 79 per cent were symptom free, 63 per cent with a negative Wassermann reaction as compared with 36 per cent in the control series, and 16 per cent with a positive Wassermann reaction. Now these figures do not tell the whole story because many of the lesions of late syphilis do not give any signs and cannot be detected on careful examination, and yet the untreated patient is nevertheless probably a poorer risk and may have on the average a shorter span of life than the adequately treated patient. Specific therapy in syphilis is definitely effective, it is a valuable procedure, and the difficulty with it is that so many patients discontinue or interrupt treatment. I have read that as high as from 70 to 80 per cent of all patients with syphilis discontinue treatment.

THE CLINICAL STANDPOINT

DR. BRUCE WEBSTER: Syphilis, unlike many other conditions, has to be treated for a long time and any scheme of treatment falls down unless the patient is kept under observation. One fundamental in planning this therapy is to have as good a contact with the patient as you can possibly have at the outset of treatment. We follow the plan of telling the patients during the first or second visit what the plan of treatment is so that they will not expect to stop each week. We tell them just a little about the reactions of treatment so that they can recognize them if they occur and we tell them the prognosis very early in the disease and try to point out the relationship between regular attendance and their prognosis.

Dr. Stokes has said, as Dr. Travell has just mentioned, that something like only 30 per cent of the patients starting antisyphilitic treatment go on to completion. We have a rather better record than that so far. Actually we are losing at the present time only about 3 per cent of the patients who come in. Some of them lapse, but 80 per cent of them have a regular attendance. The other 17 per cent are brought in with the follow-up system.

Any plan of treatment has to take into account the patient's age, his reaction to other infections and his sensitivity to other drugs, because we know that certain individuals, for instance, people with exophthalmic goiter, are notoriously sensitive to a variety of chemicals.

Lastly we must consider the condition of the patient's general health. It is important that a very careful physical examination be made and that we evaluate renal function, the condition of the teeth and a great many other things before treatment is started.

We have in the Formulary of the New York Hospital a relatively simple list of antisyphilitic drugs, namely arsphenamine, potassium iodide, neoarsphenamine, bismuth and tryparsamide. The Department of Pediatrics uses sulfarsphenamine in addition. Before discussing these drugs, I think it might be wise to say a word about the various categories in which the types of cases fall. We divide them into early syphilis, that is primary and secondary syphilis; latent syphilis, in which the condition is recognized on the basis of a blood Wassermann reaction alone; cardiovascular syphilis; central nervous system syphilis with its various subdivisions, and lastly the smaller group of visceral syphilis and syphilis of the bone, the liver and so on. Now each type of necessity has a different plan of treatment and these drugs are varied accordingly.

In early syphilis we believe, contrary to Dr. Travell, that arsphenamine is the drug of choice. I think Dr. Moore has a good discussion of that in his textbook. We were surprised yesterday when Dr. Travell and I were going over these figures, in looking at the breakdown of them, to see what a relatively small number of cases the neoarsphenamine data are based on. However, if one discusses this problem with the majority of the authorities on the treatment of syphilis, men who have had tremendous clinical experience, I think they all feel very strongly that in their experience arsphenamine has been much more effective. Perhaps they are wrong. One of the objections to arsphenamine has, of course, always been the technical difficulties involved in its administration. As you know, it has to be neutralized at the time of injection. This has been met, I think, fairly successfully.

Whatever the plan of treatment of syphilis, I think it is now generally agreed that treatment has to be continuous. The older method of intermittent treatment has, I think, been shown by the Cooperative Clinical Group to be not as effective. So, once treatment is started, it must be carried on continuously without rest periods until the end.

The question which I am sorry Dr. Travell did not have time to discuss, that of drug fastness, comes in here. It has long been known that, if therapy is carried on with arsphenamine or with the heavy metals over long periods, it loses its effectiveness and occasionally, after prolonged arsphenamine treatment, cutaneous lesions will actually recur. This phenomenon is not entirely understood but we have to take it into practical account and therefore these drugs are given in alternate courses, a certain number of injections of the arsenical followed by a certain number of injections of heavy metal. We make one exception to that, and that is in early syphilis. As Dr. Travell has said, the arsenic is excreted fairly rapidly. If a patient with primary or secondary syphilis is started on arsphenamine, the maximum amount is excreted at the end of the second or third day and the patient is left relatively without protection against the spirochete. So for the first four injections we combine arsphenamine and the heavy metal, the idea being that the heavy metal is absorbed more slowly and is in the patient's body as the chemotherapeutic agent when the blood level of arsenic is at its lowest. For that small period it does not produce drug fastness. Thus in early syphilis our plan is alternating courses of arsphenamine and bismuth, the courses of arsphenamine being longer at the beginning, with the courses of bismuth relatively short, and as the treatment progresses the arsphenamine courses are shortened and the bismuth courses are lengthened.

Bismuth, introduced in 1922 by Levaditi, is used in preference to mercury for a number of reasons. First of all, the local reactions from injections are very much less. Given intramuscularly, there is no great trouble from the point of view of pain at the site of injection. A certain amount of stomatitis occurs. It is a very mild form and there again, with proper dental cooperation by having scaling of the teeth at the beginning of every course of bismuth, very little trouble is obtained from that source. The other danger is, of course, renal damage and the urine must be followed at regular intervals of at least every two weeks during the period of bismuth injections. Fortunately, there is a tendency to recover from the renal damage caused by the bismuth.

In latent syphilis, the next type, we use arsphenamine and bismuth in this clinic. The patient is started on a course of heavy metal rather than on a course of arsenicals, so as to prevent the so-called Herxheimer reaction. In other places neoarsphenamine is often

used in latent syphilis. I think it probably makes very little difference. The courses of treatment are much the same as in early syphilis.

In cardiovascular syphilis the problem is a little different. Until a few years ago I think it was the custom to make the diagnosis of an aortitis or aneurysm and watch the patient. Active treatment with arsenicals or with bismuth was generally frowned on. As the result of the efforts of Drs. Moore, Morgan and others I think there is an increasing tendency to use the arsenicals and bismuth for the active treatment of cardiovascular syphilis. They have been able to show that first of all relief of symptoms occurs. And secondly, they believe that a good deal of healing occurs in aortitis. In cardiovascular syphilis the type of treatment depends largely on the stage of the disease. The patient with asymptomatic aortitis is handled very much as one with latent syphilis with the exception that we believe that arsphenamine should never be given in cardiovascular syphilis, although there may be a certain amount of mythology in this because we have coming to us constantly patients from other clinics who have been treated with arsphenamine and who have never had roentgenograms of the heart and the aorta. They have been taking arsphenamine for months, and when they come here we find that they have an aortitis. We stop this drug, but as I said before its dangers may be overrated. In any event it is the approved practice to restrict these patients to heavy metals and neoarsphenamine. If aortic insufficiency is present, the arsenical is started only after prolonged treatment with bismuth, and it is started in very small doses and gradually increased. If decompensation is present, arsenicals are never given until compensation is restored. Our plan is usually to treat these cases of cardiovascular syphilis for at least two years.

In central nervous system syphilis the problem is again different. There the mainstay of the treatment is arsphenamine and a heavy metal. All patients with early syphilis of the central nervous system, the asymptomatic group, we put on what we call an intensified arsphenamine regimen. That is, they are given injections every five days rather than at weekly intervals. They are given larger doses of arsphenamine than the other patients and are given shorter courses of heavy metal in between. If the disease is progressing or if there are physical signs of central nervous system syphilis, the question of tryparsamide therapy is taken into consideration. Tryparsamide was developed at the Rockefeller Institute in 1919 and has been shown to have a selective value in central nervous system syphilis. It is a dangerous drug because of its tendency to produce optic atrophy, and the visual fields have to be observed with great regularity during the administration of this drug. We begin with small doses and gradually increase the dose of tryparsamide. There seems to be less danger of visual field damage if it is done in that way. Fortunately, after the patient has received four or five injections of this drug he usually is out of danger so far as reaction is concerned. It should be remembered that tryparsamide is a very poor drug from the point of view of destroying spirochetes in the blood stream or in cutaneous lesions and so it has to be supplemented very often with arsphenamine or with heavy metals.

In visceral syphilis, again slight modifications are made. Since time immemorial potassium iodide has been given in visceral syphilis. I think it is generally agreed at the present time that its spirocheticidal activity is not very great and that its action depends primarily on preparing the tissues for absorption and producing healing in that way. It is given in large doses as an adjunct to arsphenamine and heavy metal therapy in visceral syphilis, but we give it only as an adjunct. We give iodides also in acute syphilitic meningitis with increased cell count in the spinal fluid on the basis of tradition only, because I happened to read this morning that practically none of the potassium iodide reaches the spinal fluid.

Of the other drugs mercury, of course, is a time honored agent in the treatment of syphilis. It has been used for something like 450 years. Probably you all are aware of how it first came into use. It was used in the treatment of scabies. The resemblance of secondary syphilis to scabies suggested its use and it has proved to be a valuable therapeutic agent. At the present time, as I said previously, bismuth has less tendency to cause pain at the site of injection and from the point of view of intramuscular therapy seems to be superior. At a recent conference on antisyphilitic therapy it was agreed that mercury inunction or mercury rubs still had a place in the treatment of syphilis but that place was only when no physician was available to give intramuscular injections. I think it is now generally felt that the so-called mixed treatment by mouth, which formerly had a standing, has no place in the modern treatment of syphilis.

Just a word about reactions. There is danger in antisyphilitic treatment. Actually approximately one in 12,000 injections of arsphenamine is fatal. That is based on a relatively large series. However, the risk of the disease is very much greater, as demonstrated in the Oslo series. Using the greatest amount of care both in the technic of administration and in watching for reactions, this danger of treatment can be reduced. It is very important that before every injection is given the patient be very carefully questioned for signs of reaction from the previous treatment. Fortunately, most of the complications of treatment come on gradually rather than suddenly, so that by careful questioning one can avoid them.

One of the accidents of treatment, of course, is the so-called Herxheimer effect, that is, the killing of the spirochetes in the tissues produces a local reaction which may be characterized by fever and other severe symptoms. Another one, the so-called ninth day erythema effect, occurs relatively commonly with the administration of arsenicals. The mechanism of this is not known. There are accidents of healing, as for instance scarring in the region of the coronary orifices and the consequent production of severe symptoms in cardiovascular syphilis. The dermatitis of arsenic is another serious treatment reaction. I should like to say only this about the treatment of this condition. Since time immemorial has been administered, I think on very scanty pharmacologic evidence. Now the tendency is not to administer that drug in the treatment of arsenical reactions. Apparently the recovery rate is just as good as when it is given. Jaundice, due to the liver attempting to put into play its detoxifying function and becoming damaged by the arsenicals, is another reaction which, fortunately, if the drug is stopped, usually does not cause too much damage. The important thing is to remember that if these reactions do occur the whole plan of treatment has to be altered and the patient shifted to another one of the antisyphilitic drugs.

Another important thing in this whole question of the treatment of syphilis is to know when to stop treatment. I recently saw a man who had been treated for congenital syphilis for eleven years at weekly intervals, having reactions almost every week. Based on the statistical studies of the Cooperative Clinical Group, it is now customary to terminate treatment more or less in an empirical way. We know that, if a patient has had a certain number of injections, the mathematical chances of his having any of the late manifestations are very slight. So, even if the Wassermann reaction should remain fast, as it unfortunately does in a few cases, we know now that we are justified in terminating treatment after a certain minimal number of injections.

DR. EUGENE F. DU BOIS: Those of you who spend most of your time in the wards may get an exaggerated idea of the dangers of antisyphilitic treatment. In the wards we see the bad results and not the good ones.

DISCUSSION

DR. MCKEEN CATTELL: I should like to ask Dr. Webster whether he ever employs the heavy metals by the mouth? I am thinking of the bismuth preparations.

DR. WEBSTER: No, we do not. I know but little about that.

DR. TRAVELL: I wish Dr. Webster would tell us to what extent mapharsen is used in the clinic here and whether reactions to it are seen and, if so, what type of reactions. I have read that there have been no deaths from mapharsen in several million injections up to the present time. This compares very favorable with the figures for arsphenamine which he has given us.

DR. WEBSTER: I think the important thing about mapharsen is the fact that, whereas it is apparently a very good drug from the point of view of killing spirochetes in superficial lesions, no one knows its biologic curative value. We shall not know that until groups of patients started on that form of therapy are followed for a number of years. It is important, I think, when any new drug of that sort is introduced, to know its value in preventing cardiovascular and central nervous system syphilis. We therefore are limiting its use in this clinic to patients with early syphilis who acquire the disease in the older age periods, that is, above 55, so that we are not worried about the biologic curative value in those older people. We are also giving it to patients who show reactions to the other drugs. It would appear that there is very much less tendency to produce reactions, with one exception: it does produce pain at the site of injection. It has to be given very quickly and in spite of that patients very often complain of a stinging pain along the course of the vein. It does not seem to produce thrombosis of that vein, but the pain is very often marked for some time.

STUDENT: In treating cardiovascular syphilis, what schedule do you use?

DR. WEBSTER: I had two slides that I omitted for lack of time, that bear on the question. They are compilations of the various tables in Dr. Moore's "Modern Treatment of Syphilis" and give the outline of treatment for the various types of cardiovascular syphilis according to the categories which I have already outlined: (*a*) uncomplicated aortitis, (*b*) aortitis with aneurysm or aortic regurgitation, without congestive failure, and (*c*) either of these conditions in the presence of congestive failure. The details of treatment are rather elaborate, and for them I refer you to Dr. Moore's book.

DR. WALTER MODELL: Silver arsphenamine has not been mentioned and I wondered what special value it might have.

DR. WEBSTER: I think it is generally in disrepute owing to its high reaction qualities.

DR. TRAVELL: I recall a report in which it is said that it has produced argyria in 4 per cent of the cases. There have not been any deaths from arsphenamine in the clinic here, have there?

DR. WEBSTER: No.

DR. TRAVELL: How about severe arsenical reactions?

DR. WEBSTER: We have had in all five cases of arsenical dermatitis during our clinic's existence, and we have had, I think, three cases of jaundice or hepatitis during the same period.

STUDENT: What is the argument for sulfarsphenamine?

DR. WEBSTER: The Department of Pediatrics uses it because it can be given intramuscularly in small children when they cannot get into the veins. I think that is the only argument for its use. The incidence of reactions is moderately high from it and in adult syphilis it is generally not considered a favorable drug.

DR. HARRY GOLD: Do you pursue the plan of treating known cases of cardiovascular syphilis with arsenicals?

DR. WEBSTER: Not arsphenamine.

DR. GOLD: But you do treat them with neoarsphenamine?

DR. WEBSTER: Yes.

DR. GOLD: How large a dose?

DR. WEBSTER: It depends on the category again. The decompensated group is given arsenicals only after compensation is restored. The aortic insufficiency group is given a long course of heavy metals, followed by increasing doses of neoarsphenamine. The asymptomatic group is treated very much as are the patients with latent syphilis, beginning on bismuth and giving full doses of neoarsphenamine. It is all summarized in the tables in Dr. Moore's book, referred to a minute ago.

STUDENT: Do you use arsphenamine or neoarsphenamine for visceral syphilis?

DR. WEBSTER: We use arsphenamine if there is no contraindication in the way of cardiovascular syphilis. We use arsphenamine in the clinic entirely with the exception of cardiovascular syphilis, patients who show reactions to it and, of course, the other cases in which tryparsamide is used. We also employ it as the drug of choice in syphilis in pregnancy.

DR. DU BOIS: In conclusion I should like to remind you that about thirty years ago word was spread around that a new drug, 606, would cure syphilis with one dose.

DR. WEBSTER: You might be interested to know that we have at the moment three men in the clinic who were "cured" in that way. One of them was treated just at the time that Ehrlich produced the drug, either by Ehrlich or by one of his associates.

DR. TRAVELL: For how long were they "cured"?

DR. WEBSTER: They are all being treated for neurosyphilis now.

DR. DU BOIS: The point is that even after thirty years of study of this drug we are still learning a great deal about it, and that is chiefly due to the chronic nature of syphilis.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

THE NONPROPRIETARY NAME "CEVITAMIC ACID" ABANDONED FOR "ASCORBIC ACID"

It is one of the cardinal principles of the Council on Pharmacy and Chemistry not to accept products having therapeutically suggestive names. The Official Rules of the Council provide that "names which carry the suggestion of a therapeutic indication, pathologic condition, disease, or organism causing a disease shall be considered therapeutically suggestive. Articles bearing such names will not be accepted for New and Nonofficial Remedies, because they are likely to lead physicians into prescribing names instead of remedies, and because they tend to encourage unwarranted self medication by the laity. Even if the name is at first apparently meaningless to the public, its meaning will soon be understood because patients soon learn the technical names applied to their diseases and symptoms."

The Council's function in reference to nomenclature is simply an outgrowth of its purpose: to pass on drugs. In doing so it must have a set of rules, one of which is that cited above. The Council would prefer that the discoverer of a substance coined its name; but when men who are working with products in which their interest is largely therapeutic forget or ignore the rule against therapeutically suggestive names, the Council finds itself in a position of being forced to coin a suitable nonproprietary name. Such an instance is that of crystalline vitamin C isolated by Szent-Györgyi and introduced as "ascorbic acid." Because the substance was not subject to product patent it was necessary to have a nonproprietary designation which would not conflict with the rules of the Council against therapeutically suggestive names. Although the term "ascorbic acid" had been used in the literature, the Council felt that it could not recognize this term because it conflicted with its rules. It is not as objectionable in degree as some other therapeutically suggestive terms; however, the acceptance of such a term presented the problem that it would serve as a precedent which would be embarrassing to the Council in future decisions on such names. The Council, therefore, coined the name "cevitamic acid" at the time when Merck & Company submitted the product. Announcement of this appeared in THE JOURNAL, Jan. 12, 1935, page 121.

After the publication of this announcement, objections to the term "cevitamic acid" were received from several biochemists, the two chief criticisms being the perpetuation of the term vitamin and the fact that the word "cevitamic acid" may connote nitrogen when, in reality, no nitrogen is present. In accordance with its usual procedure, the Council considered these protests and as a result it voted to reconsider the name "cevitamic acid" and directed the Secretary to consult a number of the outstanding biochemists whose opinion would be considered valuable for suggestions as to a suitable name for this preparation. From the replies that were received, it appeared that the correspondents prefer the name "ascorbic acid" and that the sentiment of a number of them is strongly against "cevitamic acid." As to the suggestion of adopting another name acceptable to all the interested parties, many of the biochemists believed that the term "ascorbic acid" has attained so much of a start that it would not be practicable to abolish it.

Consequently, at the 1938 annual meeting of the Council on Pharmacy and Chemistry the status of the nomenclature was reviewed. As a result of the discussion that ensued the Council voted that communications be addressed to the American Society of Biological Chemists and the American Chemical Society asking these organizations whether they would be willing to adopt the suggestion of the Council to recognize the term "ascorbic acid" with the distinct understanding that this is not to be considered a precedent so far as therapeutically suggestive names are concerned and that this is to be considered a concession on the part of the Council, made because it is apparent that the members of the societies did not understand at that time the fundamental reason of the Council's rule against therapeutically suggestive names. The nomenclature groups of both the American Society of Biological Chemists and the American Chemical Society have indicated their approval of the conditions under which the Council consents to revert to the term "ascorbic acid." The Council, therefore, voted to abandon the use of the term "cevitamic acid" as the official N. N. R. term in favor of "ascorbic acid," with the understanding that the term cevitamic acid is to be included as a synonym to follow ascorbic acid, and with the distinct understanding that this action is not to be a precedent so far as therapeutically suggestive names are concerned.

Council on Foods

IN AUTHORIZING PUBLICATION OF THE FOLLOWING REPORT, THE COUNCIL WISHES TO EXPRESS ITS APPRECIATION TO DR. H. J. FISHER OF THE CONNECTICUT AGRICULTURAL EXPERIMENT STATION, NEW HAVEN, WHO PERFORMED THE ANALYSES.

FRANKLIN C. BING, Secretary.

THE LOSS OF VITAMIN C IN ORANGE JUICE ON STANDING

In connection with the consideration of the product known as V-C-B (THE JOURNAL, this issue, page 2421) the Council found it necessary to evaluate evidence in support of the common assumption that orange juice may lose considerable vitamin C on standing in the refrigerator. The claim has been made that orange juice diluted with V-C-B solution retains its vitamin C concentration much better than orange juice diluted with water. In support of this contention the firm provided results of tests of the vitamin C content as determined by chemical titration of a number of solutions at different intervals of time. These experiments purported to show that fresh orange juice lost 23 per cent of its vitamin C potency on standing in the refrigerator for twenty-four hours and 34 per cent on standing at room temperature for the same length of time. A mixture of fresh orange juice with an equal volume of tap water lost more than 50 per cent of its vitamin C potency on standing in a refrigerator for twenty-four hours, whereas a mixture of equal parts of fresh orange juice and vitamin C Beverage retained more than 90 per cent of its potency when kept in the refrigerator. These results are interpreted as evidence in favor of the claim that V-C-B is an aid in preventing the oxidation of the vitamin C of natural fruit juices.

Experiments performed at the Connecticut Agricultural Experiment Station at the request of the Council do not support this claim. To test the effect of time on the vitamin C content of orange juice and other beverages in question, several solutions were prepared. Fresh orange juice was prepared from Florida oranges by reaming and straining through cheese cloth. Titration of the fresh juice showed 0.37 mg. of ascorbic acid per cubic centimeter. A V-C-B solution was prepared with a concentration of 10.49 Gm. of the dry base per hundred cubic centimeters of solution, which is equivalent to 3½ ounces of the powder per quart, the concentration suggested by the firm. Dilutions of equal parts of orange juice and the V-C-B solution, orange juice and water, and V-C-B solution and water were titrated immediately with 2-6 dichlorophenolindophenol, according to the method of Bessey and King,[1] and then divided into two parts, one of which was placed in the refrigerator and the other allowed to stand at room temperature, in stoppered flasks. At hourly intervals each solution was titrated. All titrations were made in duplicate. The average values are recorded in the table. From the values recorded in the table it may be seen that there was a slight increase in the apparent vitamin C activity as determined by titration of fresh orange juice on standing for a short time. This phenomenon has been observed

1. Bessey, O. A., and King, C. G.: The Distribution of Vitamin C in Plant and Animal Tissues and Its Determination, J. Biol. Chem. 103: 687 (Dec.) 1933.

by others and has been explained by the hypothesis that there is an initial liberation of vitamin C from some inactive precursor when foods are allowed to stand.

These experiments show that fresh orange juice, under the conditions of the experiment, retained 97.6 per cent of its vitamin C activity after twenty-four hours in the refrigerator. It is possible, of course, that if the juice should be permitted to have greater access to the air, as would be done by leaving it in an unstoppered container, a greater loss of vitamin C activity would occur. Daniel, Kennedy and Munsell [2] found that orange juice which had stood about six hours lost approximately 10 per cent of its ascorbic acid. They also found a diminution in the ascorbic acid concentration of tomato juice on standing, amounting to a loss of about 40 per cent on standing from three to four days. Mack, Fellers, Maclinn and Bean [3] found that reconstituted orange beverages rapidly lost vitamin C on standing at room temperature and lost from 15 to 30 per cent of their vitamin C on standing in the refrigerator for about one day. In the present experiments it was found that V-C-B solution diluted with an equal volume of water lost nearly all of its activity when standing at room temperature and lost considerable vitamin C potency on standing in the refrigerator. When mixed with an equal volume of orange juice, the mixture retained its activity fairly well. The results show conclusively that the only mutual effect of fresh orange juice and V-C-B solution on each other is that the orange juice retards the loss of vitamin C in V-C-B.

Destruction of Vitamin C in Different Solutions on Standing

Time, Hours	Fresh Orange Juice Ascorbic Acid, Mg. per Cc.	Orange Juice Diluted with Equal Volume of Distilled Water Ascorbic Acid, Mg. per Cc.	V-C-B Solution Diluted with Equal Volume of Water Ascorbic Acid, Mg. per Cc.	Orange Juice plus V-C-B Solution, 1:1 Ascorbic Acid, Mg. per Cc.

The chemists of Hilker and Bletsch found that only 76.5 per cent of the original vitamin C activity was left after the orange juice had stood for twenty-four hours in a refrigerator. The greater rate of decomposition of orange juice-water mixtures as obtained by the Hilker and Bletsch chemists may be explained by the fact that they used Cincinnati tap water for purposes of dilution. The well known catalytic effect of copper on the destruction of vitamin C might account for the difference, on the assumption that the tap water contained traces of the metal and that distilled water did not. The evidence, however, does not support the firm's original contention that V-C-B solution "stabilizes" the vitamin C of fruit juices but, on the contrary, indicates that the reverse is true.

It may be concluded from available evidence that fresh orange juice loses very little vitamin C potency on standing in the refrigerator, especially if protected from the air. It is also clear that solutions prepared from crystalline ascorbic acid may lose considerable vitamin C potency under the same conditions.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

V-C-B (VITAMIN C BEVERAGE BASE)

Manufacturer.—Hilker & Bletsch Company, Cincinnati and Chicago.

Description.—Powdered mixture of sucrose, dextrose, concentrated orange juice, citric acid, ascorbic acid, oil of orange and certified color.

Manufacture.—Dextrose is dehydrated; concentrated orange juice, oil of orange and citric acid are added. This material in the form of a dry powder is then mixed with the bulk of the sucrose. To the remainder of the sucrose are added ascorbic acid and certified color. The two mixtures are combined, tested for equal distribution of ascorbic acid and color, packed in airtight cans and labeled.

Analysis (submitted by manufacturer).—Moisture 2.0%, total solids 98.0%, ash 0.1%, protein (N × 6.25) 0.1%, crude fiber 0.03%, carbohydrates (by difference) 97.8%, acidity 2.04%, ascorbic acid 0.36%.

Calories.—3.9 per gram; 111 per ounce.

Vitamins.—3,000 mg. of ascorbic acid (63,000 international units of vitamin C) added for every 28 ounces of powdered mixture.

CRADLE BABY BRAND STRAINED AND SEEDLESS PRUNE JAM

Manufacturer.—Glaser, Crandell Company, Chicago.

Description.—Canned strained prune jam sweetened with sucrose. The jam may contain small amounts of added acid or pectin or both.

Manufacture.—The same as that described for Cradle Baby Brand Strained and Seedless Fig Jam (THE JOURNAL, March 18, 1939, p. 1071).

Analysis (submitted by manufacturer).—Moisture 30.0%, total solids 70.0%, water insoluble solids 1.7%, water soluble solids 68.3%, ash 0.7%, protein (N × 6.25) 0.7%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 67.5%, acidity 0.6%.

Calories.—2.73 per gram; 78 per ounce.

CELLU BRAND APPLE JUICE

Distributor.—Chicago Dietetic Supply House, Inc., Chicago.

Description.—Canned apple juice packed without added sugar.

Manufacture.—The juice is expressed from that portion of the apple which is not used for the preparation of Cellu Brand canned Apple Rings (THE JOURNAL, Sept. 17, 1938, p. 1101). The juice is strained and filled into cans; the cans are vacuum sealed and heat processed. The spray residue on the apples used is kept within the federal tolerance.

Analysis (submitted by manufacturer).—Moisture 88.5%, total solids 11.5%, ash 0.1%, fat (ether extract) 0.2%, protein (N × 6.25) 0.04%, reducing sugar as invert 6.2%, sucrose (by copper reduction) 3.6%, crude fiber 0.0%, carbohydrates (by difference) 11.2%.

Calories.—0.47 per gram; 13 per ounce.

MILLER'S BRAND EGG NOODLES

Manufacturer.—Miller's Food Products, Inc., Los Angeles.

Description.—Egg noodles prepared from hard wheat flour, water, egg yolks and salt.

Manufacture.—The ingredients in formula proportions are mixed, mechanically kneaded, rolled and cut. The cut noodles are dried and packed.

Analysis (submitted by manufacturer).—Moisture 11.8%, total solids 88.2%, ash 1.6%, fat (ether extract) 4.3%, protein (N × 6.25) 13.5%, crude fiber 0.4%, carbohydrates other than crude fiber (by difference) 68.4%, lipoid phosphoric acid anhydrous (P_2O_5) (dry basis) 0.153%, total phosphoric acid anhydrous (P_2O_5) (dry basis) 0.443%, estimated egg solids (dry basis) 8.3%.

Calories.—3.66 per gram; 104 per ounce.

SUBDURAL HEMATOMA

In 1925 Putnam and Cushing [1] called attention to the striking differences between the mechanism of production and process of organization of the posttraumatic extradural hemorrhage and subsequent clot and the same factors in the subdural hematoma. The rare occurrence of subdural hematoma after skull fractures or after intracranial osteoplastic explorations, as well as its delayed reaction to trauma, suggests to them some individual predisposition of the meninges favorable to the subdural seepage of the blood. Kunkel and Dandy [2] have recently stressed certain peculiarities in the pathology of subdural hematoma. The clot does not organize evenly throughout. There may be a large collection of dark fluid blood with a few soft brownish yellow clots. The fluid blood when left standing in a test tube will not clot. The outer membrane is always thick and is attached to the dura. New vascular channels from the dura connect with newly formed blood spaces in the membrane. The inner membrane is thin, transparent and avascular and lies loosely on the pia-arachnoid. The clot has frequently a laminated appearance. Putnam believes that neither the laminated appearance nor the presence of well preserved red blood cells in the clot constitutes an argument for successive hemorrhages. The more or less uniform localization of the hematoma and the absence of any signs of injury to the underlying brain are among other characteristic features. The source of hemorrhage is probably a torn pial vein or a torn sinus. Kunkel and Dandy were not able to ascertain the source of hemorrhage in any of their cases.

While the microscopic appearance of the membrane in pachymeningitis haemorrhagica interna of Virchow and in traumatic subdural hematoma is similar, Kunkel and Dandy point out that both the etiology and the gross appearance are at variance. Virchow's pachymeningitis haemorrhagica is a condition seen at necropsies on elderly decrepit persons with histories of insanity, chronic alcoholism or syphilis. Virchow put forth the theory that in these cases the dura becomes chronically inflamed, as a result of which there is a pouring out of fibrin and blood-tinged fluid. The lesion itself is a solid thick membrane with little or no blood, whereas a subdural hematoma possesses thin membranes and a large volume of blood.

Subdural hematoma is important because it is not nearly as infrequent as was formerly held. It can be diagnosed early, and timely surgical intervention almost invariably results in a cure. The traumatic origin of the lesion is now generally accepted. In cases without such a history it is felt that trauma may be trivial and therefore forgotten by the patient. The clinical and operative observations in such cases are identical with those in which there is a definite history of trauma. Spontaneous disappearance of a subdural hematoma is highly improbable. Unless relieved by operative intervention the patient would succumb to the effects of increased intracranial pressure long before there could be much absorption of the blood.

In Kunkel and Dandy's series of surgical cases at the Johns Hopkins Hospital between 1914 and 1935 there were forty adults, six minors and two infants. The symptoms are essentially those of increased intracranial pressure. On the basis of an analysis of forty-four cases Jelsma [3] lists, as most important and constant, latent period, lucid interval, headaches, mental changes, drowsiness, motor disturbances, change in reflexes, disturbances of the cranial nerves, remission of symptoms and coma. Among less important symptoms are vomiting, nystagmus, sensory disturbances, variation in temperature, pulse and respiration, abnormal fundi, xanthochromic spinal fluid and leukocytosis. The latent period may last from a few days to several years. The average duration is about twenty-five days, while the average for the lucid interval is probably ten days longer. Kunkel and Dandy state that in 53.2 per cent of their cases there were no positive localizing neurologic signs, that 40.3 per cent possessed them in part, and that 6.7 per cent had neurologic signs referable to the uninvolved hemisphere. A presumptve diagnosis of subdural hematoma was made in their series in only twelve cases (23.3 per cent). The diagnosis is difficult because symptoms in no way differ from those produced by any intracranial space occupying lesion. In the presence of history of trauma to the head followed by symptoms suggestive of hematoma, trephining or making burr holes, preferably on both sides, are indicated for diagnostic purposes. Kunkel and Dandy would add ventriculographic study in cases yielding negative results. The choice of operation seems to be the reflection of a small osteoplastic flap with the removal of the hematoma. Of the forty-eight patients operated on, forty-six cures are reported. Here clinical research again demonstrates its value for medical progress.

WHAT'S IN A NAME?

Ask the advertiser—he knows! The scientific discoverer who is not primarily interested in advertising sometimes finds a name for his discovery that packs an unintended punch. Indeed, the genius who invents a substance sometimes is more baffled by the problem of inventing a name than by the intricacies of discovery. For substances with therapeutic actions, a name that designates this action or use seems to be a convenient short cut out of the difficulty. Unfortunately this path has been taken by nostrum makers and quacks so long and so often that it has become a highway of quackery. The inventor who takes this path may come to be classed with the company that he keeps. The intention may be different, but the effects do not depend on the intentions. "Pink Pills for Pale People" is more obvious to people than "Hematogen," but only for a while. Certainly doctors soon realize the significance of such names as "ascorbic acid," "calciferol," "aneurin," "vasopressin," "klotogen" or even "ergometrine." Not all of these preparations are likely to be used for indiscriminate self medication, but physicians may easily be misled by the overemphasis on the one action and use which the name suggests, to the neglect of the limitations of that action.

Another "easy way" of misusing names is the use of numbers or the letters of the alphabet. This method was popular for "Thompsonian number —" and "Humphrey's Homeopathic Specific, numbers — and —" and also in many catalogues of drug houses and in old hospital dispensaries. Most physicians now realize that such designations are dangerous, first because they are easily confused and second because they tend to schematization and thus to obstruct scientifically critical thinking.

There are a few exceptions to these objections, conspicuously in the case of specific serums and vaccines, just because they are truly specific. In the case of an endocrine organ which includes several principles with different actions it may be advisable to differentiate by designating the actions until other properties may be utilized. In the case of vitamins the alphabetical designations were introduced and tolerated as a temporary expedient. Now they have become so entrenched that it will take years to displace them, though a determined effort is being made to substitute the chemical names as the pure substances become available. These seemingly justified exceptions illustrate the difficulty of temporary compromises. It is difficult to kill a name once it has struck root. If it is displaced, confusion follows and the scientific literature is encumbered for many years. Much better and much easier is avoidance of a false start. The Council on Pharmacy and Chemistry has no wish to invent names, although it must sometimes do so. It is glad to be of help, to give an opinion about contemplated names in their relation to its rules. It has established contact with the nomenclature committees of the American Society of Biological Chemists and the American Chemical Society. The Council may be addressed in care of Secretary, Council on Pharmacy and Chemistry, American Medical Association, 535 North Dearborn Street, Chicago. It is suggested that the best time to initiate consultation is before the name is finally adopted.

THE CASE OF BRUNSON V. FISHBEIN

On Friday June 2 in the Federal Court at El Paso, Texas, Judge Boynton instructed a jury which was hearing the case of *Brunson* v. *Fishbein* to bring in a verdict in behalf of the defendant. In this case the plaintiff, Dr. Asa Brunson, who was treating tuberculosis with inhalations of a secret preparation, felt that he had been damaged because of a telegram sent by Dr. Fishbein to DeWitt Wallace, editor of the *Reader's Digest*. In January 1938 Mary Rose Bradford, wife of Roark Bradford, well known author, sent DeWitt Wallace a telegram asking whether or not he would be interested in an article dealing with the work of Asa Brunson, claiming that Brunson had cured more than 3,000 cases of tuberculosis and that he may be a second Pasteur. Mr. Wallace forwarded the inquiry to Dr. Fishbein, who telegraphed in reply that Dr. Hruby of the Chicago Municipal Tuberculosis Sanitarium had investigated the Holderness-Brunson treatment in 1921 and quoted from an article bearing Dr. Hruby's name which appeared in the Chicago *Herald and Examiner* stating that the method was a dangerous fake. To this quotation Dr. Fishbein added the statement that similar treatments tried elsewhere have also failed.

In defense of the case the American Medical Association produced testimony by three chemists, Schoeffel of the American Medical Association's Chemical Laboratory, Harris of the University of Oklahoma at Norman, Okla., and Muehlberger, chemist and toxicologist for the coroner's office and the Cook County Hospital, all of whom stated that an analysis of the product used by Brunson revealed that it contained approximately 95 per cent liquid petrolatum, 3 per cent oil of eucalyptus, 1.5 per cent mint camphor or menthol, and traces of pine oil and thymol. The American Medical Association also produced in evidence death certificates of a considerable number of persons whose testimonials were being circulated by Brunson as being cured of the disease by his treatment, the death certificates indicating in each instance that the patients had died of tuberculosis. Moreover, testimony relative to the nature of the disease and methods of treatment was supplied by Drs. Allan J. Hruby, Chicago; L. J. Moorman, Oklahoma City; Samuel H. Watson, Tucson, Ariz.; H. J. Corper, Denver, and O. E. Egbert, El Paso, Texas. In addition the Association was prepared to offer Dr. H. S. Randolph of Phoenix, Ariz., and Dr. R. B. Homan of El Paso and a vast number of depositions. There appeared also on

the stand on behalf of the American Medical Association Drs. Felix P. Miller of El Paso and Dr. Morris Fishbein. In behalf of the plaintiff, Asa Brunson, there appeared only himself.

Because of the great educational value of the testimony in this case and particularly because of the tremendous interest aroused by the publication of the testimony in the case of *Brinkley* v. *Fishbein*, it is proposed within the next few weeks to publish also an abstract of the testimony in the Brunson case. The decision was not only a victory for the American Medical Association in its campaign to protect the public against nostrums and unestablished remedies for serious diseases but also a notable victory for scientific medicine in relationship to the diagnosis and treatment of tuberculosis. The educational value of the trial was incalculably great. Many persons attended the various sessions; the testimony itself will be widely quoted because of its concise presentation of the present status of our knowledge of tuberculosis.

Current Comment

LOCAL INTESTINAL IMMUNITY

In order to test the possibility of an acquired local intestinal immunity, Torikata and Imaizumi [1] administered daily doses of heat-killed colon bacilli to guinea pigs, with control immunizations of other groups by routine subcutaneous methods. Ten days after the final administration of this vaccine, serums were withdrawn from each group of animals and expressed tissue juices (presssäfte) prepared from the intestinal walls. Control serums and tissue juices were prepared from nonvaccinated guinea pigs. Titrations of the serums and tissue juices thus obtained showed an 80 to 100 per cent increase in the opsonic titer of the intestinal tissues as a result of the oral vaccine but only a 10 to 20 per cent increase in the opsonic titer of the blood serum. Animals immunized by the routine subcutaneous method showed in contrast a 76 to 100 per cent increase in the opsonic index of the blood stream, with less than half of that percentage increase in the intestinal tissues. The Japanese immunologists conclude from these data that oral immunization with heat-killed B. coli is effective in rendering the intestinal tract refractory to homologous infections long before an effective humoral or somatic immunity is produced. Previous investigators have concluded from clinical evidence that, even though nonviable oral vaccines may not be demonstrably effective in producing specific agglutinins in the blood serum, they do produce a "tissue preparedness" for subsequent immunization. While most professional immunologists are skeptical of conclusions drawn from opsonic titrations owing to the numerous sources of error in such tests, the data reported by Torikata and Imaizumi encourage the continued examination of evidence relative to the route of administration of vaccines.

STUDIES ON RHEUMATIC FEVER

Recent studies on rheumatic fever by Schultz and Rose [1] have yielded facts with suggestive diagnostic implications. Determination of the glutathione content of erythrocytes and of the catalytic potency of the blood in rheumatic fever as well as an investigation of the dextrose tolerance curves of persons with this disease did not yield particularly striking results. An investigation of the novel formol-gel reaction of Gaté and Papacostas [2] in a number of febrile diseases with particular reference to rheumatic fever, however, led to interesting observations. In patients with various febrile diseases it was found that, in general, a parallel was demonstrable between the erythrocyte sedimentation rate and the results of the formol-gel reaction, the incidence of positive gel reactions varying directly with acceleration of the sedimentation rate. In patients with rheumatic carditis, however, negative formol-gel reactions were often observed early in the disease, although at the same time the sedimentation rate was rapid. Later, on development of active carditis, a positive gel reaction was frequently observed even in cases in which the initially high erythrocyte sedimentation rate had declined. The experimental observations on a number of patients with rheumatic fever indicate that a strongly positive gelation reaction in children, or in adults in the absence of arthritis, is suggestive of active carditis. Persistently negative reactions, however, although associated with an accelerated erythrocyte sedimentation rate, indicate that severe carditis probably is not present. From these observations it would appear that the formol-gel reaction may be a valuable additional aid in the diagnosis of active rheumatic carditis in patients suffering from rheumatic fever.

HEARINGS ON THE WAGNER HEALTH BILL

In this issue of THE JOURNAL appear abstracts and condensations of hearings on the Wagner Health Bill held before the subcommittee of the Committee on Education and Labor of the United States Senate on Thursday, May 25. In THE JOURNAL for next week and subsequently thereto will be published further abstracts and condensations of such hearings. The facts brought out appear to be of the utmost importance to the medical profession and indeed to all the people of this country. About June 1, Senator Murray of Montana, who is chairman of the subcommittee, is reported to have said officially that the hearings on this bill will continue throughout the present session of Congress and that it was not likely that either the Wagner bill or any modification of the Wagner bill would be reported out of the committee during the present session. The subcommittee of the United States Senate appeared greatly impressed with the data presented by the American Medical Association and requested much additional material, which should certainly have considerable effect in determining the attitude of the Senate toward this legislation.

ORGANIZATION SECTION

ABSTRACT OF HEARINGS ON THE WAGNER HEALTH BILL

The subcommittee of the Committee on Education and Labor of the United States Senate met, pursuant to adjournment, in room 357 of the Senate Office Building, Washington, D. C., at 10 a. m., May 25, Senator James E. Murray presiding. Present were Senators Murray (chairman), Ellender, Taft and Holt. Also present were Senators Wagner and Holman.

STATEMENT BY DR. ROCK SLEYSTER

Dr. Rock Sleyster:—Mr. Chairman, and members of the committee:

I am speaking as the President of the American Medical Association. This organization now includes in its membership 113,113 practicing physicians out of a possible 145,000 practicing physicians in the United States.

We come to you with a statement relative to legislation that you have under consideration. This statement was adopted at St. Louis last week at our annual session of our House of Delegates, a session which was attended by 7,500 members of our organization. The House of Delegates of the American Medical Association is the policy-forming body of our Association. It is democratically elected by the Houses of Delegates of the various state medical associations, and they in turn are elected by the delegates of some 2,000 county medical societies.

The American Medical Association has a headquarters building in Chicago with some 600 employees.

Among the various activities, there is a Bureau of Medical Economics that has been busy for some years assembling factual data on everything that pertains to the care of the sick. We have there the largest amount of information on physicians, hospitals, medical schools, laboratories, in fact, any institution which pertains to sickness, that is available anywhere; in fact, at the time of the World War the Medical Department of the United States Army came to us for assistance, which we very gladly and willingly gave, and it resulted in 45,000 medical physicians entering the service in the army, the navy, the United States Public Health Service, the selective draft boards, and so on.

The Association has constantly offered to governmental agencies our full cooperation in everything that we might do in meeting these problems and has offered freely of its facilities at all times. I do not think that anybody would be more interested at this time in helping with preventive medicine where need can be shown and where need is available.

We come to you today offering our cooperation and all of our facilities and our advice.

At this point, Mr. Chairman, I would like to introduce to you Dr. Edward Cary, Past President of our organization and chairman of our legislative committee.

STATEMENT BY DR. WALTER DONALDSON

Dr. Edward Cary, Chairman of the Legislative Committee of the American Medical Association:—Following the National Health Conference in July 1938 the House of Delegates of the American Medical Association met in special session in Chicago Dec. 15, 1938. At that time the Interdepartmental Committee Report was taken up and was referred to various committees. The chairman of the committee which had this report in hand is here. At the last meeting of our Association at St. Louis, the Wagner bill was taken up and referred also to the committee of which he was chairman. I take great pleasure, Mr. Chairman, in presenting Dr. Walter Donaldson.

Dr. Walter Donaldson, Secretary, Pennsylvania State Medical Society, Pittsburgh:—This report was adopted by our House of Delegates after hearings for the consideration of the Wagner bill conducted just about as you are conducting hearings here on this subject, for the purpose of obtaining opinions, information and advice from our members and the House of Delegates. Throughout the two days and nights that we were in session, our committee was constantly receiving the advice and help of scores of these delegates.

Senator Ellender:—Doctor, was any opposition expressed by members of your Association?

Dr. Donaldson:—Do you mean—

Senator Ellender (interposing):—I mean was anybody favorable to it?

Dr. Donaldson:—To the Wagner bill?

Senator Ellender:—Yes.

Dr. Donaldson:—There were people that were favorable to certain features of it, yes, sir; and they appeared as witnesses before the committee.

Dr. Donaldson presented the report adopted by the House of Delegates May 17, 1939, without dissenting vote (See THE JOURNAL, June 3, p. 2295).

Senator Ellender:—Dr. Donaldson, you said that before the House of Delegates in St. Louis you heard witnesses just the same as we are now hearing before this committee. I would like to know who were those witnesses. Were they all members of the American Medical Association?

Dr. Donaldson:—There were three witnesses who appeared representing hospital associations.

Senator Ellender:—Was any opposition expressed before the House of Delegates? I mean was anybody in favor of the bill that appeared before the House of Delegates?

Dr. Donaldson:—There were, yes.

Senator Ellender:—As I understand, the resolutions adopted were unanimous?

Dr. Donaldson:—Yes, there was no objection against it.

Senator Ellender:—I would be interested, Doctor, if you could tell the committee how it would be possible for the states to receive aid under the proposition which you advanced on page 8 of your statement, which says "Any state in actual need of financial aid from the federal government for the prevention of disease, for the promotion of health, and the care of the sick, should be able to obtain aid in a medical emergency without stipulating every other state to seek and to accept similar aid and thus to have imposed on it the burden of federal control." *How would you do that?*

Dr. Donaldson:—Well, I would say that those who advised and discussed that feature at our hearing had in mind some such agency as now exists in the federal system here for obtaining loans or grants for approved activities. Perhaps they had in mind the Reconstruction Finance Corporation, the RFC.

Senator Wagner:—You mentioned the restriction of financial grants. Just how did you consider that a state which needed aid would proceed or what legislation would be necessary to provide it?

Dr. Donaldson:—I should think that the state represented by its health officer would come here accompanied by others who were interested in the health problems of the state and make their proposal to an agency already set up, and having administration—

Senator Wagner (interposing):—What agency, for instance?

Dr. Donaldson:—A new agency which I would describe as being similar to this Reconstruction Finance Corporation.

Senator Wagner:—You mean to borrow money from the federal government?

Dr. Donaldson:—Borrow money or receive a grant. As I understand it, federal money has been given in instances where there have been great disasters, without any expectation of its being returned or getting it back.

Senator Wagner:—Then you are not opposed to federal aid, are you, to the states, to help preserve the life of the people within the state?

Dr. Donaldson:—If it has been properly presented by the local representatives.

Senator Ellender:—Well, from the testimony so far adduced before this committee, it was the idea of all, as I understood it, to have the bill apply only to the poor and the indigent, those who really could not provide adequate medical aid. That, as I understand it, is the purpose of this bill. If the language is not clear on that, I want to have it clarified, and if you or anybody else of the witnesses who will testify will point out that the well off as well as the poor are to be treated alike, I would like to have that pointed out.

Dr. Donaldson:—I can assure you that it will be pointed out, and I think that you will find it in the text of some of the manuscripts that have been laid on your desk.

Senator Wagner:—I do not see anything in the report which suggests any amendment to the act. I understood you to say,

and the reports say that you are in sympathy with the general objectives of the bill, although you disapprove of the methods. Do you know whether you or some other witness will present proposed amendments to the act?

Dr. Donaldson:—I believe no amendments will be proposed.

STATEMENT BY DR. R. G. LELAND

Dr. Cary:—Mr. Chairman, since the organization of the American Medical Association in 1847, the underlying motive has been the education of its membership and of doctors generally throughout this country, and of the public health, and it was only in 1931 that the American Medical Association felt the need of the bureau which we call the Bureau of Medical Economics. I have here present a gentleman who is the head of the Bureau of Medical Economics, which was established in 1931. I present Dr. R. G. Leland.

Dr. R. G. Leland, Director of the Bureau of Medical Economics of the American Medical Association:—In order that there may be greater facility in understanding some of my statement, unless you already have copies of this booklet entitled "Factual Data on Medical Economics, 1939, Bureau of Medical Economics, American Medical Association of Chicago," I should like to present them to you.

Senator Murray:—We will be glad to have the copies.

Dr. Leland:—The bill now pending before your committee is obviously based on the report of the Interdepartmental Committee, and that report in turn is based on the report of its Technical Committee. The report of the Technical Committee seems to be based on figures assembled by that committee that the committee itself seems to regard as supporting the thesis that death and sickness rates in the United States are excessive; that this excess depends not on economic conditions but on inadequate medical service, and that by expending a vast sum of money under federal supervision the sickness and the mortality rates can be substantially reduced. The figures relied on by the Technical Committee to support its thesis are believed to be incomplete and the deductions drawn from them are believed to be unwarranted by any available evidence. The conclusion that the reduction of sickness and mortality rates awaits only large federal and state appropriations, expended under federal supervision and control, is believed to be without foundation.

The constant improvement in the health of the people of the United States that has been in progress many years, as shown by official vital statistics, has been made under the prevailing system of medical and hospital care. No evidence has been advanced to show that the rate of improvement would be accelerated by the revolutionary changes proposed in the pending bill.

The death rates from some causes are approaching the vanishing point; the death rates from other causes are far more favorable than has been represented by the advocates of this legislation. More knowledge is needed before a reduction in the number of deaths from still other causes can be expected or predicted.

Statistics of the nature and amount of prevailing illnesses at any given time are not sufficiently complete or accurate to justify positive conclusions based on them, but so far as they are available in the United States they show a trend toward a general improvement except with respect to cancer, diabetes and diseases of the heart and blood vessels. These diseases are the accompaniments of advancing years and their increasing prevalence is associated with a greater concentration of the population in the ages above 45 years. This greater concentration above 45 years of age has occurred under the present system of medical care.

The Technical Committee of the Interdepartmental Committee seems to have drawn its conclusions largely from data assembled in connection with the activities of the Committee on the Costs of Medical Care and the National Health Survey conducted by the United States Public Health Service. Data assembled by the Committee on the Costs of Medical Care, however, were not assembled in such a manner and form as to permit the conclusions of that committee in respect to the costs of medical care to be weighed in relation to the costs of the other necessities of life, nor did the conclusions of that committee point out with any degree of exactness the elements that have entered into the increase in the costs of medical care in such a way as to suggest a method of reducing those costs. The basic data assembled by the National Health Survey, distinguished chiefly by its massiveness rather than by the validity of its conclusion, was necessarily collected by persons not adequately trained for the purpose, and the conclusions drawn from the data so assembled were based on more or less arbitrarily established standards. Unless your committee bears these facts in mind, it may be misled by the recommendations of the Interdepartmental Committee based on the work of its Technical Committee.

Time will not permit a detailed explanation of all the charts that have already been placed in your hands. However, I should like to point out the general features of a few of them. [Dr. Leland then emphasized many of the points brought out in the publication "Factual Data on Medical Economics."] The distribution of physicians is governed largely by general economic conditions over which the medical profession has no control. The average annual change in the number of physicians has varied from an increase of 5,485 in 1898 to a decrease of 385 in 1920-1921. The present average annual net increase in the number of licensed physicians in the United States is about 1,500.

In 1938 there was an average daily census of 132,454 empty beds in general hospitals. During the period 1928-1938 there was a net increase of 61,987 beds in general hospitals. During the same period the unoccupied beds increased by 8,919.

In 1929 the number of beds in general hospitals registered by the American Medical Association was 293,301, or 2.35 beds per thousand of estimated population. In 1937 there were 412,091 beds in the registered general hospitals, or 3.19 beds per thousand of estimated population. During the period 1925-1937 the expansion of general hospitals amounted to 118,790 beds, a net gain of 40.5 per cent. In the same period the population increased (according to population estimates) by 12.5 per cent.

The maximum occupancy of general hospital beds during 1938 was at some point between four and five beds per thousand of population, with of course marked differences at each end where the beds per thousand of population were one or two, or at the other end where they were between five and six or more. It is impossible to predict what the occupancy would be if the beds per thousand of population were increased to seven or more. There are areas where as yet hospital facilities have not been provided largely because of sparsity of population, the lack of competent personnel to staff the hospitals and the inability of these communities to support such hospitals. There was in 1938 a low bed occupancy in most states which had a low number of beds per thousand of population. The general death rate for the United States when compared with the standardized annual death rate for the industrial policy holders of the Metropolitan Life Insurance Company, meaning the persons who pay their premiums on a weekly or monthly basis (some 17,700,000 people), show that the trend of the decline of death rates among the low income wage earners employed in a variety of occupations compares favorably with the trend for the general population. The death rate from cancer is often mentioned with great alarm. The mortality from cancer does show an increase, but it must be understood that a greater portion of the population than in previous years is now living beyond the age of 45 years where cancer is more prevalent as a cause of death. The percentage of change in maternal mortality varies from an increase of 1.5 per cent in one state to a decline of 38 per cent. The problems pertaining to maternal mortality are to be found more largely in urban areas and among other races than in rural areas and the white race. The decline in infant mortality has varied from 38 per cent for Maine to 62.2 per cent for Connecticut. The recorded infant mortality rates for the original registration states declined 53.1 per cent from 1915 to 1937. For the expanding birth registration area the decline has been 45.6 per cent.

The present lowering of the death rates from many causes is a primary result of the present system of medical practice. If any group of countries having comparable racial stock has at any time been able to produce better results than those in the United States, we shall be glad to receive such a list of countries in order that we may examine the evidence.

Senator Murray:—Doctor, notwithstanding the record that you described, it is true, nevertheless, that in some sections of the country there is a possibility of making great improvements in the care of the sick and those who are unable to pay for medical attention?

Dr. Leland:—Granted.

Senator Murray:—Have you gathered any statistics on the extent of that condition in this country? Have you made any exploration of that?

Dr. Leland:—We have, sir.

Senator Murray:—You know that in many sections of the agricultural states there is a serious deficiency of medical care and attention for the people who need medical care, do you not?

Dr. Leland:—I am not prepared to say exactly the extent to which the need exists.

Senator Ellender:—Doctor, I notice on page 2 of your testimony the statement "In 1938 there was an average daily census of 132,454 empty beds in general hospitals."

Dr. Leland:—Yes, sir.

Senator Ellender:—Those, of course, refer to all hospitals?

Dr. Leland:—No; general hospitals.

Senator Ellender:—What do you mean by a general hospital?

Dr. Leland:—A hospital to which the general population goes for its ordinary illnesses, not special hospitals such as nervous and mental diseases or tuberculosis.

Senator Ellender:—Those are pay hospitals, are they not?

Dr. Leland:—Most of them. There are a number of general hospitals that are now being maintained by some governmental units.

Senator Ellender:—By that statement you would not indicate that those beds could have been filled if there was a need for them? That there could have been sick people who could have occupied them but because of their lack of money they were not able to be taken in?

Dr. Leland:—We have called attention in the past to the fact that there may be in the United States in various sections people who, because of economic barriers, are unable to obtain necessary treatment, but the extent to which that exists is still somewhat questionable in exact terms.

Senator Ellender:—Has the Association made any effort to determine to what extent it is necessary?

Dr. Leland:—The Association has made a study.

Senator Ellender:—Is that available to the committee?

Dr. Leland:—That statement is now under process of being put together.

Senator Ellender:—Would you be able to make it available for the committee?

Dr. Leland:—I should be glad to, yes, sir.

Senator Wagner:—Doctor, I want you to believe me when I say that any questions that I ask you are for the purpose of being enlightened if I can by the medical profession.

Dr. Leland:—Certainly.

Senator Wagner:—And also, I am hopeful of their cooperation rather than their resistance.

Dr. Leland:—That is right.

Senator Wagner:—On the question of the need for medical care, I read in the papers that there was a report submitted to your convention which stated that there were only 44,000 people in the United States, the survey showed, that were really in need of medical care who did not receive such care. Do you remember that report?

Dr. Leland:—I was not in the House of Delegates when that report was given. My attention has been called to the fact that that report was made, and I should say that I have read the transcript of the report that is to appear in THE JOURNAL. However, that report was not based on a complete study. We have only issued a preliminary statement of certain outstanding facts, and this report of the 40,000 stands much in contrast to the 40,000,000 and is not intended at this time to be interpreted as an exact figure.

Senator Wagner:—I notice here in this book that you have submitted, which is very interesting and has some very interesting charts, that on the last page you have a chart of medical service and economic status.

Dr. Leland:—Yes, sir.

Senator Wagner:—I will ask you if I can get a little more light as to the meaning of this chart. You have there "above $3,000—self sustaining, no special arrangements needed." Then "$3,000 to $1,500—for the most part self sustaining, largely self sustaining but sometimes needing help." When you say "for the most part self sustaining" I suppose that means for medical care?

Dr. Leland:—It means as to the necessities of life and everything.

Senator Wagner:—Including medical care?

Dr. Leland:—Yes.

Senator Wagner:—Then you have "below $1,500—variable needs for economic and medical assistance."

Dr. Leland:—Yes, sir.

Senator Wagner:—Then there is a need that at this time you mean is not supplied?

Dr. Leland:—I think you will find sir, in the explanation on the opposite page, that those amounts that are stated on the chart are not intended to be rigid and fixed amounts, because we realize, as I believe you do, that in various sections of the country $1,500 would mean that the man or the family would be living on the fat of the land, and therefore those parts of the country cannot be compared with other parts in which $1,500 is inadequate.

Senator Wagner:—I understand; I do not mean to hold you down to anything but an approximation. I believe it has been shown that about one third of our people, which would be about 40,000,000, have an income of $750 a year or less. If there is a lack of medical care in that very small group comprising about 40,000,000 people, would you think that your survey was reasonable when you say that only 44,000 out of that 40,000,000 have sufficient medical care?

Dr. Leland:—I will be glad to give you the answer to that, Senator, when I get the complete returns.

Senator Wagner:—Are you in sympathy with the general objectives of the legislation?

Dr. Leland:—I see no objections to the general objectives. I think every one of us wants to help people who are in need of medical care.

Senator Wagner:—I have always said that about the medical profession, that they render a great and an unselfish service, but we are all going to try with you and with your guidance and your cooperation, I hope, to bring about even a better and more helpful life. Is your Association ready to propose any amendments to this legislation that will bring it more in harmony with your views?

Dr. Leland:—Of course it would not be proper for me to speak for the rest of those who are to make statements before you, but from my observation of the consideration that has been given this bill, I believe it is the consensus of opinion that in order to do that would require so many changes that the House of Delegates took the action that Dr. Donaldson presented to you. I believe that they have not offered or are not bringing to your committee any suggestions for amendments. We did however suggest a little different approach, as was contained in the report of the House of Delegates. That is the offer that we have instead of amendments.

Senator Wagner:—You are generally acquainted with the workmen's compensation laws of the different states?

Dr. Leland:—Yes, sir.

Senator Wagner:—Do you know that those laws provide for cash benefit payments for injuries and also for payments for medical care?

Dr. Leland:—Yes, sir.

Senator Wagner:—The doctors are great advocates of the workmen's compensation law, first because it is a humane law, and secondly because I believe 9 per cent of it is for medical care, and the doctors receive compensation in that way, and I wonder how you could reconcile that advocacy with your statement here that you are mixing medical payments with loss of wage payments; I just wondered why you oppose it in one instance and favor it in another?

Dr. Leland:—There is a statement that will be presented if the committee likes, but, if the committee desired, there is an opportunity there to enter into a very interesting discussion of the initial theory on which the workmen's compensation law was based. I might say that it began with paying very little and in some cases almost no attention to medical care, which was brought in later on because it was found necessary in order to conserve the funds.

Senator Wagner:—I do not think that you are speaking of the law in New York, because it so happens that I introduced the law in New York in 1913, and we coupled them right together.

Dr. Leland:—It is my understanding of the workmen's compensation laws that the laws were intended to place the responsibility for injuries due to employment on the employer, to spread it perhaps over the general population by including the cost of the insurance in the cost of the product. It has been found necessary to add more and more medical services, but in many instances it has been done very badly and the medical profession has objected to the kind of medical care and, even under workmen's compensation, has been doing as much as it could to improve those conditions.

Senator Wagner:—You try to repeal the New York workmen's compensation, and the doctors would be one of the groups that would oppose it, and rightly so.

Dr. Leland:—I am not suggesting that.

Senator Taft:—In this question of the fundamental difference between what these figures meant of the 40,000,000 and the 40,000 which should be at least contrasted before the comparison as to what they mean is resolved, the 40,000 would mean, I assume, only the people who are not within reach of doctors and hospitals and has no relation to their economic status? Is that correct or not?

Dr. Leland:—That is partly correct. On the other hand, the information that has been given out has left the impression, or the implication, that these 40,000,000 people that are so frequently referred to are sick all the time, 40,000,000 of them every day. Obviously I hope no one believes that, because there is only 2 per cent of the population as found by the Committee

on the Costs of Medical Care that can be considered as ill on any given day, although the National Health Survey did find 4.5 per cent ill on any one day or, rather, on the day of the survey. Of course, one needs to correct many of the characteristics that enter into figures. Figures are means of expressing facts, and sometimes they give impressions that are not exactly facts. The National Health Survey was made during the time of the year when the sick rate was the heaviest, between November and March, and of course the 4.5 per cent would be more than twice as much as reported by the Committee on the Costs of Medical Care or that has been generally accepted as the ratio of the amount of sickness. But, now, as you have intimated, one needs to understand what these figures mean. I would prefer that the committee do not consider the 40,000 to which reference has been made as an exact figure.

Senator Taft:—I understand that, but what I want to get is, when you get the exact figure, what does it mean? What is it supposed to mean?

Dr. Leland:—Supposedly the 40,000,000 people are people in the very low income classes. The 40,000 to which reference was made are also in the low income classes.

Senator Taft:—That means 40,000 people what; what category do they come into, people that cannot get medical service?

Dr. Leland:—As reported to the House of Delegates, it was 40,000 who were denied medical care. Now, there is quite a difference between the word "denied" and the inability to get medical care. Some people do not want medical care, they do not desire it.

Senator Taft:—They would rather go to chiropractors?

Dr. Leland:—Exactly. They would rather go to the drug store and treat themselves. The statement that was made was to the effect that the figure would be more likely to be 40,000 than 40,000,000 who would be denied medical care, meaning the people who sought medical care and who had been turned away—refused it.

Senator Taft:—It is different from the number who might have lack of means and not be in touch with a hospital.

Dr. Leland:—Very different.

Senator Taft:—So really there is no comparison whatsoever between the 40,000,000 and the 40,000

Dr. Leland:—No comparison at all.

Senator Murray:—And there are a great many people, of course, who are unable to pay for medical care themselves, and the only way they are able to secure it is through some charitable organization or through the representatives of such agencies or the help of friends or neighbors?

Dr. Leland:—That is right.

Senator Murray:—And that amounts to a considerable number, does it not?

Dr. Leland:—I think that when our study has been finally put together we can show you a very large volume of illness that is cared for through those voluntary services of physicians, hospitals, nurses, health departments, official and voluntary health agencies and many other organizations that are now carrying a tremendous load without complaint.

Senator Ellender:—Doctor, with further regard to this report that we asked you to submit and which you said you would, I notice on page 2 of your statment you have criticized the methods applied by the National Health Survey. How did you proceed to obtain the data on which you expect to make this report?

Dr. Leland:—You are referring to our report?

Senator Ellender:—Yes.

Dr. Leland:—The American Medical Association study of medical care was a study quite different from any other that has ever been made to my knowledge. I have investigated and collected information pertaining to some 4.000 surveys of various kinds. The Committee on the Costs of Medical Care brought in very properly the cost of medical care, the duration of illness and many other factors on which to base different information. The National Health Survey had a little different approach to find out how much chronic illness was prevalent in the country. They developed, however, something more than just a chronic disease. It was our desire to know to what exent the people of the country were actually utilizing the services and facilities that are now available. That is quite a different matter, from telling us how many days a person is sick and how many people are sick on a given day. That study was made by dealing not only with physicians but with nurses, dentists, hospitals, health departments, pharmacists, with the voluntary and official welfare agencies, with various mutual associations and organizations in the community such as trade unions, who have mutual benefit plans.

Senator Wagner:—One other question I would like to ask you: Your association, I take it from the report, did recognize that there was need for federal aid or that there may be need for it, for federal aid based on needs, I think was the language used.

Dr. Leland:—We recognize that there is need for assistance to a great many people in time of illness. Now, whether that is federal aid or local aid or state aid is a matter we believe largely for local determination. Where the local people do not have the money with which to help these people they have to get help, perhaps from the state. If the state is unable, we conceive it to be desirable that the federal government listen to their needs and allow them to show, to prove their financial ability as a state as a need which actually exists, to consider it and to give them either a grant or a loan.

Senator Taft:—Let me see, Doctor—do I understand that the American Medical Association would submit an alternative plan if requested to do so?

Dr. Leland:—I think this also is something that will be discussed by some other speakers, but in answer to that question I believe it is the disposition of the American Medical Association if such legislation were to be drafted along lines suggested in the report which Dr. Donaldson read that the American Medical Association would, as it always has, offer its facilities to the government in order to be of some service in its conception of that kind of legislation, but we are not in the business of drafting laws ourselves.

Senator Taft:—I do not quite understand the distinction. Of course, we could not pass a law permitting federal assistance to one state unless the law also permitted federal assistance to every state. That is all that this law does. It is in the alternative, and no state has to take it unless it wishes to do so. I think it is important that the American Medical Association make clear a distinction which I do not understand. If the distinction is that this plan gives too much power to the federal government, that is a conceivable distinction, but I do not quite understand this idea of preferring the RFC to the Social Security Board or purely on a needed basis. That could be taken care of by the distribution of funds provided in the bill, and while I do not ask you to do so I think the decision ought to try to make it clear so that I can get it in my mind what the distinction between the program is of the Association and that proposed in the Wagner Health Bill.

Dr. Leland:—I may say that the other speakers will elaborate on that more fully.

Senator Murray:—Doctor, do I understand that you devote your time exclusively to medical economics?

Dr. Leland:—That is right.

Senator Murray:—You are not a practicing physician or surgeon?

Dr. Leland:—I have not practiced since the war.

STATEMENT BY DR. HAVEN EMERSON

Dr. Cary:—Mr. Chairman, the next speaker that I would like to introduce we think has had the very greatest experience and in all probability will be able to elucidate the subject as well as or better than any other witness we know. I have great pleasure in presenting to you Dr. Haven Emerson, professor of public health practice, College of Physicians and Surgeons of Columbia University, New York City, and former Health Commissioner of New York City, and a present member of the Board of Health of New York City.

Dr. Haven Emerson, professor of public health practice, College of Physicians and Surgeons of Columbia University, New York City:—The record of progressively improving health in the United States of America for the past fifty years and particularly for the past eleven years impresses me with the trustworthiness of the official and voluntary agencies and institutions and methods of local, county and city and state government developed by long experience and appropriate adjustment for prevention of disease and care of the sick.

No emergency of sickness or neglect faces us. No spectacular or immediate improvement in general health can be expected through extensive changes in procedures, in responsibility, or in sources of funds as proposed in the Wagner bill.

Better national health can be assured by development along well established lines in the orderly evolution of social and professional resources made available by new medical knowledge.

Better care of the sick, and more nearly universal availability of the increasingly costly facilities for diagnosis and treatment, can be assured by extension of the various promising experiments such as voluntary prepayment and cash indemnity plans than can be expected from attempts to have the cost of sickness transferred to the federal government or by relying on state and local health officers to administer treatment facilities at public expense.

We, as physicians, whether engaged in individual practice of curative medicine or as officers of health concerned with the

administrative application of preventive medicine for local and state governments, advise against disturbing a series of services which have a long history of success, by creation of another policy where local responsibility will be largely at the mercy of federal dominance and allocation of funds.

Estimates of neglected sickness have been much exaggerated. Theoretically possible benefits from large additional expenditures are too optimistic and problematic to be convincing.

As the major cause of insufficient care for the sick and for health, where these exist, is lack of earning power and the dislocation of commerce, industry, production and demand for goods, characteristic of the past eleven years, so it will be the reestablishment of sound economic and employment conditions which will correct the error, rather than large spending programs by government which do not lead to any basic improvement in the incomes of wage earners. Neglected sickness is less often the cause of economic misfortunes than vice versa.

The best contribution that could be made by the federal government to general health would be by reestablishment of confidence in self support, and encouragement of private industry, earning capacity and productive employment.

Federal spending for the sick and for health cannot be relied on as a panacea for such inadequacies as can be shown to exist.

There are measures which only the federal government can take to advance national health:

First, the putting of its own administrative machinery in good order, by which I mean the development of a single federal agency, whether bureau, board or department, under which all federal health and medical functions (except those of the army and navy) should be served.

The chief executive office of such a federal health service should of course be professionally trained and experienced, as have been a long line of Surgeon Generals of the Public Health Service.

Only through such a single federal agency should state health officers have relation to the federal government for consultative advice, common policies or financial aid when emergency or persistent economic difficulties prevent a particular state, region or population unit from receiving protective and other medical care necessary for the people's safety and security of life.

Among the many administrative disadvantages of the Wagner bill provisions is the triple headed character of federal direction through which grants in aid of states for six separate and distinct functions would be administered.

If grants in aid are needed in the future, as they have often been needed and made in the past, for health and medical care, the allotting of funds should be in response to specific and proved evidence of need and request for aid by a particular state or group of states presented by the state health officer to the federal agency authorized to extend financial aid, and preferably with confirmation of the need and the extent of it by officers of the Public Health Service.

Grants should not be offered or urged on the states to promote some federal theory of social improvement, nor should grants be made to any state which is able to finance its own appropriate program of health services and care of the medically needy. It seems to us unreasonable to suppose that every state in the Union needs federal aid to carry out the functions of government long recognized as duties of the state or its political subdivisions.

It is obvious to those of us who have observed even the relatively modest extension of federal subsidy for prevention and treatment of syphilis that often the funds were out of proportion to the supply of trained persons capable of technical competence in epidemiology, medical treatment and administrative direction of services.

Such a program as is proposed for hospital and health center construction and extension of health agencies into the fields of obstetrics, diseases of childhood and care of the crippled (orthopedics) would quite inevitably face at least a temporary frustration on account of unpreparedness of professional experts to make the services effective.

It is obvious that those who have shared in drafting the Wagner bill have confused in their minds the duties or functions and capacities of the health officer with those of physicians and surgeons concerned with care of the sick.

Health officers, except where appointed on a purely political basis, are selected because they are professionally trained and experienced in sanitation and preventive medicine, a specialty as distinct from internal medicine or surgery as plumbing is from carpentry.

In states where health officers follow one another in rapid succession with the alternation of party control of state governments, it would be a calamity if the development of the elaborate series of services for personal care of the sick, of the expectant mother, of the infant and child were left to the direction of the state health officer.

It is wholly undesirable to have any state or federal plan for care of the sick depend on the leadership, professional direction or financial control of the state or local health officers. Those that are competent are more than fully occupied preventing and controlling disease and directing sanitary measures for health. Those that are not specialists in health are even less qualified as experts in the intricacies of services for the sick.

If, as is threatened, the invaluable functions of the United States Public Health Service for industrial hygiene, which have brought such benefits to labor and industry, and such credit to the commissioned officers of the service, are to be transferred to the Department of Labor there will be another confusion and duplication of interest and expense similar to that so long exhibited by the medical and health functions of the Children's Bureau, which should of course be a division of the United States Public Health Service.

Briefly, we advise that before attempting any such costly and considerable revolution in the source of funds, in regulation and supervision of health and medical services in the states by the scheme of federal subsidies, in the complicated manner proposed in the Wagner bill, the intent of the President's Executive Order 7481 should be carried out, and "better coordination in federal health work" to be the first concern of the Congress.

We offer our professional support for any well considered plan to aid backward, economically unfavored states to have health and medical care equal to that of the rest of the country, and we suggest certain principles on which a sound federal program of needed grants might be based.

We oppose the Wagner bill as it is at present offered for consideration because it appears to us to be unnecessary, costly and subversive of sound relationships between federal and state financial resources and governments, and we very much doubt whether the results hoped for by its proponents would be achieved if the present bill were to be enacted into law.

Senator Wagner:—Dr. Emerson, do you favor the provisions of the present Social Security Act which give grants based on needs to states for the care of children and for medical care?

Dr. Emerson:—I am familiar with the original setup under the Sheppard-Towner grants and the extension of them under the Social Security Act. I do not know of any evidence which would indicate that the progressive improvement in infant health and maternal health is in any way related to the federal assistance that has been given to the states in that regard.

Senator Wagner:—Then you oppose it?

Dr. Emerson:—No, I think if the federal government has spare money and it wants to encourage the states to do what the states have not been ready to do, then I see no impropriety in proposing such an offer, but I doubt myself whether that is an important factor in the astonishing improvement which has occurred in infant mortality where those services have not been at the federal expense.

Senator Wagner:—Of course, there are those who disagree with you on that. Do you think it is a coincidence that with this aid there has been an improvement?

Dr. Emerson:—Senator, at the time that I was born the infant mortality was 250, and there has been a steady and progressive improvement until last year when it was 38, continuous and uninterrupted improvement regardless of any federal intervention in the local health services.

Senator Wagner:—Are there occasions where the federal government ought to aid in health services at all of the states?

Dr. Emerson:—Yes, I should say that the policies which have been adopted in the past of so-called grants in aid made available through the Public Health Service at the request and with the cooperation of the states has been a useful contribution to the extension of full-time county health services, and certain sanitary improvement in certain of the states of the country where they were unfortunate because of climatic or geologic or economic conditions. That, to my mind, if I may refer to some of the other questions that have been asked before, is an essentially different situation from the present proposal to have a large federal fund which they are pushing—which the federal government is pushing on all of the states to take advantage of for the sake of encouraging them to spend more than they otherwise would be willing to spend. The fact that Alabama or Georgia or Texas because of the economic difficulty of their people are unable to finance what we would call a minimum well rounded public service quite justifies those states asking for an equalization of wealth, if you choose to call it that, but having an amount from the federal government by application of the state to the Public Health Service—well, I

think that those have been an admirable effect and have been helpful and I think that that principle is a sound one, but it seems to me totally different from the principle presented in your bill which proposes that every state, our own very wealthy state producing 65 per cent of the income of the United States taxes, should have to come to the federal government to run its public health service. I do not know of any women and children in New York State or City who ought to look outside of the city and state for humane and competent medical care. We have the resources, we have the persons, we have the wealth, we have the interest in taking care of our own people.

Senator Wagner:—Of course, the United States has a concern in the health of the citizens, just as the individual states have, and New York State has asked for aid and has accepted aid, but you think that that was entirely unnecessary?

Dr. Emerson:—Well, Senator Wagner, we are all of us human. If you have forty-eight health officers who are told that they can get some more personnel and more salaries by going to Washington and asking for it, they are all going to come.

Senator Wagner:—You do not think it has contributed anything to improving the health of the people at all?

Dr. Emerson:—I think that the money given for the hastening of adequate programs for the control of syphilis has probably abbreviated some of the sicknesses and the communicability of that disease. I do not know of any reason why New York City or New York State should have excused themselves out of meeting those expenses out of their own money. They have plenty of money in the state of New York to do that, but if anybody offered them $75,000 for a lot of field services or a lot of treatment clinics, they are not going to be bashful about asking for it.

Senator Wagner:—A number of surveys have been made indicating the great need for additional medical care in New York as well as other places.

Dr. Emerson:—Well now—

Senator Wagner (interposing):—I know your records, Commissioner. Perhaps you are a little more conservative than I am, but you are not only a very eminent doctor in our state but have been a great public official. I am prepared to say that, but I differ with you on this. And there is another thing: You have been interested and have written a great deal on the subject of health, and you did urge some years ago—and I am wondering whether or not your views have changed—a study at least of health insurance, compulsory health insurance.

Dr. Emerson:—That was twenty or twenty-five years ago.

Senator Wagner:—It was 1932, was it not?

Dr. Emerson:—That I recommended state compulsory health insurance?

Senator Wagner:—I will read what it says:

> The committee urges the broadest sympathy toward experimentation in promising fields, together with the most searching analysis of results. We believe that experimentation along the lines of both voluntary and required health insurance, along with the other experiments in the group purchase of medicine, should be promoted and carried on. In all likelihood, in certain areas of the country, and from certain population and economic groups, required health insurance would be found to be more feasible and practicable than voluntary health insurance or vice versa.

By "required health insurance," by that you mean compulsory?

Dr. Emerson:—Yes.

Senator Wagner:—That is quoted from your report.

Dr. Emerson:—I suppose that is still true. We were thinking of the rather unusual success of the Saskatchewan experiment, where the people by the authority of Parliament at Ottawa were to bind themselves to hire a doctor to provide for the care of their municipality or, roughly, a county as we should say it, and it is conceivable that there should be conditions in one or more rural areas of the United States where the only way that the people can tempt doctors into their community is to hire doctors by the municipality. It is conceivable. Up to the present time I have known of no such instances being developed. I think that is a report which conceivably can apply to a very few scattered areas in the United States as it is in Canada.

Senator Wagner:—In those cases you see no objection to the intervention of the government to aid, do you?

Dr. Emerson:—If the people of a community cannot tempt doctors on their own free initiative to come to their community because they cannot pay enough to draw them from elsewhere, they will want to take such resources of pooling their income that will underwrite or guarantee to the doctor a reasonable living wage. Of course, one of the ways that is being done, and the American way of settling that, has been to provide so far as possible local hospitals; in other words, a doctor nowadays needs a shop, and a group of doctors in a community needs a shop, and they have avoided hiring doctors in groups rather by the method of trying to provide a competent hospital wherever it can be afforded, and where there is professional personnel competent to operate it.

Senator Wagner:—Doctor, you remember that we had a constitutional convention last year?

Dr. Emerson:—Yes, sir, a great one.

Senator Wagner:—And which I happen to remember.

Dr. Emerson:—Yes, sir, a great one.

Senator Wagner:—I am glad to hear you say that. Among other things, we did provide for a constitutional amendment which would permit the enactment of a state insurance law.

Dr. Emerson:—Yes, sir.

Senator Wagner:—In which the state itself would be permitted to lend its credit or make contributions toward those efforts, and that was submitted to the people as a separate proposition.

Dr. Emerson:—Yes, sir.

Senator Wagner:—And there were a great many of the medical profession opposed, sincerely of course, to it, and on this same theory that it is no part of the governments' business, and yet that was submitted to a vote, and as you know it received the highest vote affirmatively of any of the nine amendments proposed.

Dr. Emerson:—I remember.

Senator Wagner:—So that that expresses the views in New York. I hope that you are not going to give the answer which Dr. Booth gave me, who said "Well, the people don't know what they need and we do."

Dr. Emerson:—Now, Senator Wagner, I gather that you have omitted from your bill all reference to compulsory health insurance?

Senator Wagner:—Yes, I have. Would you favor it if I included it?

Dr. Emerson:—It would add one more nail to its coffin, to my mind.

Senator Wagner:—Then you do not agree with the vote by the people of New York?

Dr. Emerson:—I voted against it when it came up for the referendum, because I believe the people do not understand what it would mean. I think there is a rational difference of opinion between physicians who have studied the effects of such policies elsewhere and what they believe would occur under our own conditions of government. I am afraid that I am not confident that we have yet achieved such independence and competence of our elective and appointive officers that we could turn over the practice of medicine to them.

Senator Wagner:—I do not know whether you appeared or not, Doctor, but we had quite a discussion at a number of hearings before the committee that had it under consideration.

Dr. Emerson:—I read those; I was not present.

Senator Wagner:—And a long discussion on the floor and a long discussion before the people; and I take it that you agree with Dr. Booth that they just don't know what is good for them, and they did not know what they were doing?

Dr. Emerson:—No, I would not say that. But I think there are honest people, that many people have been led in the thought to believe, largely by the tremendous prestige of influences from Washington, that the solution—

Senator Wagner (interposing):—That was a state convention.

Dr. Emerson:—The people of New York have been largely influenced, I am sure certainly in the cities, by the belief that developed out of Washington to some extent that a compulsory system will relieve them of the financial difficulties in the care of the sick, and I believe that they are uninformed as to the truth of that, but that is their belief and that is on our statute books. We believe that there is a proper way of doing it. I have no criticism whatsoever of the proceedings of the convention. I think it was admirable to put that before the people, and they certainly voted for it unequivocally, but the legislature, you will notice, has not taken advantage of the permission.

Senator Wagner:—There is a commission still studying it.

Dr. Emerson:—Yes, it is a fine thing to study it. I believe there are two states that recently have rejected it on practically the same basis. There are evidently in the country differences of the citizens' attitude with regard to the involvement of their state government in the provision of medical care of the sick.

Senator Wagner:—Although I say that you are very eminent, I wanted to bring out that there are some in New York that differ with your point of view.

Dr. Emerson:—Yes, I know.

Senator Wagner:—I have agreed with you a lot, as you know.

Dr. Emerson:—I remember, we have collaborated in the same city government at times, and I think the Board of Health of New York City is not always entirely satisfactory to all of the citizens, as we may guess from present conditions.

Senator Ellender:—Dr. Emerson, I notice on the last page of your statement that you think according to this, that all citizens, no matter where located, should receive the same health and medical care as that of any other citizen of any other state.

Dr. Emerson:—I don't think I say that.

Senator Ellender:—That is just what I wanted to ask you. You say "We offer our professional support for any well considered plan to aid backward, economically unfavored states to have health and medical care equal to that of the rest of the country, and we suggest certain principles on which a sound federal program of needed grants might be based." What do you mean by that?

Dr. Emerson:—I mean this, that if there can be shown that the reason they are not getting it is because of economically unfavorable conditions, the government must come in and help those people in those states, but there aren't a great many states where the failure is a failure of the state government, a failure of professional organization perhaps, a failure of adequate institutions which the states can properly correct. It does not seem to me, in other words, that just because there are some people in some places that cannot get medical care that it is the function of the federal government to come in automatically and right that, but there are conditions, with spendable income as we were told not long ago, of about $120 per capita in one of the states, and on that basis those people are not able to contribute the sum necessary to give them well developed health protection, and to assist that, I should say it was distinctly a function of the federal government to respond to an appeal for aid by those states.

Senator Taft:—Do you think that the right of self government includes the right to govern yourself badly if you want to?

Dr. Emerson:—Yes, as long as your bad government does not hazard the health of your neighbors. If you run an incompetent health department on the border and start an epidemic of smallpox, we thank the Lord that we have a public health service that will come in and intervene on the basis of interstate commerce and help us avoid spreading it.

Senator Ellender:—With further reference to this paragraph that I just called your attention to, would you be surprised that I told you that in some states—let us take the great state of Texas that is rich in natural resources—there was evidence produced before this committee not pertaining to this bill but on another bill whereby it was testified that fifteen corporations control the oil, gas, sulfur and salt of that state, and they pay taxes to that state aggregating $100 to a revenue of $8,000,000 that was distributed among New Yorkers, Pittsburghers and Philadelphians. I say that because of that situation where these natural resources are being taken from certain sections of the country and are being as it were taken away and profits brought to other states and that is causing a lack of proper financial aid for such needs and medical care in many, many states of the Union.

Dr. Emerson:—Is it true that in the state of Texas the state and the communities pleaded poverty as the reason for their inability to get medical care?

Senator Ellender:—Why, my Dear Doctor, if you were to go before the state legislature of Texas, and I know this for a fact and it is not hearsay—they have tried time and again to get the Legislature to put a proper tax on these natural resources and they have never been able to do it, because somehow, through the control of the big interests, they do not seem to be able to do it. They tried that in Louisiana for many years up to 1928 when Huey Long came on the scene, and the picture was changed, so that today the state of Louisiana offers to its people wonderful medical care compared to what it was prior to that time. If all of the states were able to take the money in the form of natural resources within their borders and where just a few are able to snatch it out and carry it to New York or Maryland or Ohio or Indiana, the probabilities are that we would not be confronted with such legislation as is incorporated in this bill.

Dr. Emerson:—Well, after all, one state after another does correct the abuses which have been developed by monopoly, and if Louisiana did it with Huey Long, perhaps there will be somebody in Texas—

Senator Ellender (interposing):—That is only one out of forty-eight that has succeeded, and I doubt if any others will try.

Dr. Emerson:—Yes, but many others were already taxing.

Senator Ellender:—Very few.

Senator Wagner:—Doctor, you were the head of the committee that conducted the survey the results of which were afterward published. I saw the publication several weeks ago, which you tried to point out and did point out a lack of medical care in New York, a lack of beds in hospitals. Do you remember that?

Dr. Emerson:—The hospital survey of New York I was responsible for directing, and that was like any other local community undertaking, and an attempt to discover to what extent there was a lack of proportion between facilities and needs. We found that there were some facilities in excess of the needs, chiefly in the matter of beds for maternity patients. Apparently we have enough beds until 1960 at the present rate of the birth rate. There were other kinds of beds which were insufficiently provided, and the object of that was not to show that New York could not afford to take care of its sick but that it must include in its city plan for the next twenty years a methodical replacement of old beds and buildings and new beds, and I think that you will recall from that report that we showed that, while we had been spending about $20,000,000 a year for new hospital construction and replacement, there was needed possibly $28,000,000 in the immediate future to make sure that a balanced program of hospital facilities would be achieved.

It is quite true probably that in New York you will find some people that either do not ask or do not know that they want medical care. Recently we had some 11,000 calls made on the Henry Street nurses for care, calls by the poorest people, and they analyzed each case to find out whether they had medical care and found out why not, and they found approximately 1.4 per cent of that 11,000 poor people with no obvious availability of medical care which had yet been obtained. That is the kind of thing that we must expect. We were dealing with 11½ millions in the metropolitan area population, and we found deficits here and failures of distribution there, and our report was a plan for building up to 1960 for an assumed growth of population which we can reasonably predict. It was not a disclosure that I think would be interpreted by anybody as indicating that there was a gross inadequacy in the care of the sick in New York.

Senator Murray:—Doctor, in corroboration of the statement made by my colleague Senator Ellender, I want to suggest that we have a situation in my state of Montana where we have a large mining camp that has produced over 2 billion in wealth in this country. It is a hazardous occupation—mining—and there are diseases that develop from mining known as silicosis and yet, notwithstanding all of that tremendous production of wealth, these men were unable to secure proper care and attention. They did not have any hospitalization facilities, and it required a desperate struggle here in Washington to get a small allocation to enable them to extend those facilities here during the last year. For a great many years they went without compensation for accidents, and of course there are a great many accidents occurring in mines there daily. The result is, as Senator Ellender has so well stated, they are not getting a fair deal, and we hope that something is going to be done about that situation to see that there is better distribution.

Dr. Emerson:—I understand that you are asking us to approve of this as a method of adjusting social errors?

Senator Murray:—Oh no, I was just merely stating that fact incidental to the discussion.

Dr. Emerson:—You are referring to the copper and not to the Homestake Gold Mines, where apparently very admirable services are provided. You are referring to the Butte situation?

Senator Murray:—Yes.

Senator Ellender:—Doctor, I desire to ask you one more question. How would you carry on this equalization of health service to the rest of the country? As I interpret this paper, in order to be equal?

Dr. Emerson:—I do not think there is any possible way of making all states equal, because some will go far ahead of others.

Senator Ellender:—Yes, some will go further than others. You are the third or the fourth witness who testified this morning that you are in accord with doing that, and the statements so far have been general. What we would like to have is something specific as to how that can be carried out, because, as I understand this bill, that is its purpose.

Dr. Emerson:—I believe that the mechanism that has been used in the past would be adequate if applied consistently now, the mechanism by which sums of money have been appropriated and made available for the use by the public of public health services or the grants in aid to the states for specific improve-

ments in the public health. Now, the sums were relatively small but they were extremely economically applied. They were applied in a way to encourage the maximum state of collaboration, the maximum of elucidation of state initiative and support, and they were used only in those states where there was a perfectly obvious deficit which the state from within its own resources could not make up. I do not admit that there is any condition in New York and many other states of our part of the country which cannot be better corrected within the state and within the state government and the resources than by running to Washington and asking to correct it, and I am familiar with the serious conditions of lack of sanitation, lack of health services and some instances where lack of medical care prevails where an appeal to the federal government ought to be responded to.

I believe the Public Health Service and the Public Health Service alone through a sufficient central body to operate any federal grants in aids rather than creating three different groups with 240-odd advisory councils to deal with those complicated services offered in the bill—I believe the Public Health Service would be sufficient.

Senator Ellender:—To what extent would you be willing or how far would you go toward giving aid? What specific purposes? Would you go as far as this bill in granting aid in the methods that you have just suggested?

Dr. Emerson:—I should be inclined to begin by applying aid for the fundamental protective and preventive services that the people cannot do alone, in other words, what I would call the establishment of full-time county health services for the prevention of disease. That seems to me the first object of the federal expenditure for the assistance of states that can show that they cannot afford it themselves.

Senator Ellender:—Only preventive medicine then?

Dr. Emerson:—I believe that to be the first object. I do not believe it is the function of the state or national government to take care of women in confinement or to take care of babies or to take care of other things which are the functions of the practice of medicine and which can be better handled by local communities than it can by aid from Washington. I believe that the most intelligent expenditure of what you might call stimulating money for the health of the nation would be in the field of prevention rather than in the field of the care of the sick. I think the ordinary instincts of the United States are sufficiently developed so that whenever it is called to our attention that there are neglected sick people nearby in the counties and states, that you will find provision made to take care of them. But it takes a great deal of imagination and a great deal of statesmanship to spend for the preventive mechanism. The people do not see that close enough. I believe that it is the proper functioning of the federal government to assist the states that cannot do it themselves to have a really well developed, a well rounded full-time public health service based on a county and state organization. That would seem to me to be the first object and the only really immediate object for which this expenditure might be asked.

Senator Ellender:—If that is true then, as I understand it, you are really against what this bill provides for no matter if it were carried out the way you suggest, that is, through a central office in Washington, that the government should not spend money for that purpose?

Dr. Emerson:—Perhaps we are differing merely in a point of degree. I believe that so elaborate a plan involving so many different things is premature and that, until we have tried it on those bases which we know are necessary, it will be inadvisable to commit ourselves to these others in which I believe there is no good evidence that our federal aid is indispensable.

Senator Ellender:—I was just wondering, Doctor, in connection with the other hearings we had here some time ago as I recall it, the southeastern part of the United States, I think, we account for—that is most of the Southern states—14 per cent as I recall it of the babies of the nation, and that community has 2 per cent of the wealth of the nation. Now, I am just wondering how that locality can cut down that death rate that is so prevalent among the babies there so as to keep our population up?

Dr. Emerson:—I believe that you will find that the infant mortality rate in those states has been declining at very much the same rate as it has been elsewhere, and for similar reasons, the reason being better food and milk and water and care, and that they have benefited by the improvement of the protective services just as the state of New York and Massachusetts have.

Senator Ellender:—We had a witness that testified two weeks ago, as I recall, who said that the death rate had declined it is true, but that in contrast to that the birth rate, that is, the number of women who have children, had declined to such an extent that it has now reached the point of 2.7, and 2.6 would be on a decline, and he further stated that if we could provide for adequate measures whereby we could further cut that death rate among children that even with the decline in the birth rate we will be able to have a bigger crop of children. What have you got to say to that?

Dr. Emerson:—I am afraid that is a little confused. Since 1931 the married women of child-bearing age in the United States have not borne enough girl babies to reproduce themselves, so that we are now potentially facing a falling population. You will see this most beautifully illustrated physically at the World's Fair in the Hall of Man, and you will notice that there is no conceivable way in which by improvement of the death rate we can catch up with the birth rate when the number of babies born is not sufficient to reproduce their mothers.

Senator Ellender:—I do not expect you to catch up with it—

Senator Ellender (continuing):—I mean us instead of you—but the point made there was that, even with the declining death rate, if we could better provide for those born alive we could raise more of them and keep the population up.

Dr. Emerson:—Well—

Senator Ellender (continuing):—In other words, I do not remember the exact date which he set, but in the next twenty years I think he said—I may be wrong as to that—that instead of being 2.7, which is on the borderline, it might soon be 2.5 and we will simply be decreasing.

Dr. Emerson:—There is no doubt about it decreasing. There is no doubt about it, and there is no statistical probability that we can by further reduction of the death rate alter that. The only way—

Senator Ellender (interposing):—You may prolong the time in which it is to come.

Dr. Emerson:—Since 1931 we have been in a deficit position, and that is likely to increase. No country has found any way of bribing women to have more babies than they choose.

Senator Wagner:—You did state that you are in favor of some legislation, but the distribution of the funds should be based on need?

Dr. Emerson:—I believe so.

Senator Wagner:—And that it should be limited to preventive medicine rather than to these other fields in which this bill attempts to give state aid?

Dr. Emerson:—Yes, sir.

Senator Wagner:—Would you favor it if this bill were amended—I do not agree with you—but would you favor it if that was the provisions of the bill?

Dr. Emerson:—If new legislation is necessary in order to make it possible to make federal grants to aid of states in the public health, I should believe it ought to be drafted and I assume that it is necessary to have new legislation.

Senator Wagner:—Would you say that it ought to be on a matching basis or simply an outright grant to a state?

Dr. Emerson:—Well, I believe that a state ought to show its good will always in asking for aid that it is willing to go a little further itself. That is the way these grants in aid have been made in the past, and I understand the principle that, if the federal government allows something to assist them, the state should stretch itself a little more to go part of the way. I recognize that as a sound principle.

Afternoon Session

After Congressman Albert E. Austin, Fourth District of Connecticut, appeared in opposition to the bill, the hearing proceeded with representatives of the American Medical Association:

STATEMENT OF DR. MILTON ROBB

Dr. Cary: We think there is another angle to this question of public health, particularly public education. I present Dr. Milton Robb, Detroit, who will speak on the program of health education.

Dr. Milton Robb:—A program of health education has been in progress in this country for many years, initiated chiefly by the various state medical societies of this country, and must be continued in increasing amount for undoubtedly the lack of health education is responsible for a larger proportion of insufficient medical care than the absence of availability of medical services.

What I have to say will specifically relate to the state of Michigan and her efforts in health education. However, I know that a duplication of these efforts can be found in forty-five other states, depending on their needs.

The American Medical Association, through its Bureau of Health Education, has aided in every way possible the development of these programs in the many states, as well as the development of an unusually extensive one of its own.

[Dr. Robb then described public health education in Michigan.]

The problem is not to bring to the door of every one something they as yet do not feel they need, but the problem is to

educate every one to the need for a periodic health examination for the prevention of disease, and early medical attention when signs of disease appear.

The child with middle ear disease which is having smoke blown in its ears by its father or hot oil put in by its grandmother for the earache, the man with an acute appendicitis who takes castor oil for his bellyache, the young woman with tuberculosis of the lungs who continues self medication with a cough mixture, be she rich or poor, are not having adequate medical care. It is obvious that the fault lies with the individual. If there were a doctor on every street corner and a government hospital on the next square, and service could be had for the asking, there would still be many people who would not stop to get it. In other words, it is a problem for the educator.

The Michigan State Medical Society eighteen years ago through its council asked the University of Michigan to cooperate with them in the formation of what is called the Joint Committee on Health Education. The objective, as set down at that time, was as follows: "The function of the Joint Committee is to present to the public the fundamental facts of modern scientific medicine for the purpose of building up sound public opinion relative to the questions of public and private health. It is concerned in bringing truth to the people, not in supporting or attacking any school, sect or theory of practice. It will send out teachers, not advocates."

The record of these activities shows that audiences increased from a few hundred in 1922 to 240,000 in 1930; and those who served voluntarily as lecturers increased from twenty in 1922 to 576 in 1930.

In 1930, in the high schools of the state, assembly hours were granted for this purpose, and in 100 high schools five assembly hours a year were devoted to this program, under the direction of the Joint Committee on Health Education. The audiences were composed of approximately 140,000 high school students.

In addition to this, a health column was offered to the newspapers of the state which by 1930, through the medium of some sixty daily and weekly newspapers, reached an estimated number of 2,000,000 readers.

In 1931 the depression caused the withdrawal of most of the supporting contributions, and therefore the program was greatly curtailed.

In 1935 the committee decided on a renewal of these activities and increasing the scope of the program. At this time it became evident that other professional and lay organizations would add to its effectiveness. Previously there had been thirteen health agencies of the state interested in supporting this health education plan.

At the present time practically every organization connected with education and more particularly health education is included in its membership.

For the past two years the activities of the committee have centered on two programs, one on school health and the other on adult health. The subcommittee on health education in schools is composed of leading educators in the health sciences and in the school system of the state.

In Michigan the expense of the entire public health education program was borne by contributions from the various organizations comprising the committee and other Michigan philanthropies and not from the taxes of the state.

The American Medical Association has been extremely active, as I stated before, in health education, and the following summary is based on information in the files of the Bureau of Health Education for 1938. [Here Dr. Robb summarized the work of the Bureau of Health Education for 1938 as shown by the Board of Trustees report.]

This review of the health education activities of the American Medical Association is offered as evidence of its established policy to disseminate scientific information pertaining to health and medical services.

Thus praying for the continued extension of health education in the interest of still better national health, allow me to repeat in conclusion that the lack of health education is responsible for a larger proportion of insufficient medical care, regardless of station in life, than the absence of availability of medical service.

Senator Wagner:—That is interesting and I agree with everything that is said, but don't you think that there are many people in the low income group that you do not reach with this worthy type of educational service?

Dr. Robb:—I presume there are some that are not interested in reading. We do try to cover the entire population in every way, and in our efforts we have what we thought made a rather successful attack. It is rather peculiar—I have always felt that they may know about where to get the grocer and the butcher, but sometimes they do not seem to find out where they can get the best type of medical service that can be given.

Senator Wagner:—Are there not many that have not the means to pay for that service?

Dr. Robb:—Yes, but in Detroit I know and in the state of Michigan we have a number of organizations that take care of them entirely free and have always done so, so I do not believe that that is much of a factor if at least they will only know where to go.

Senator Thomas:—Doctor, I am assuming that you believe so much in health education programs that your association is supporting fully the general education bill now pending?

Dr. Robb:—I cannot tell you that.

Senator Wagner:—You would not oppose it just because it was a federal activity instead of a state activity?

Dr. Robb:—Not unless the people at home who I feel know all of the needs vote for it.

Senator Wagner:—Are you opposed to this bill?

Dr. Robb:—I do not know the bill, Senator.

Senator Murray:—Your theory is that the health education program would contribute largely to overcoming the conditions that are sought to be remedied by this bill?

Dr. Robb:—I believe it will overcome a great deal of it if we can advise the people where to go for that service.

Senator Taft:—Your experience shows that a state can do it without federal aid if they go out and do it.

Dr. Robb:—It has been done pretty generally in the state of Michigan and we have quite a big state.

Senator Wagner:—Haven't you any aid from the federal health service at all?

Dr. Robb:—I believe that we have gotten some; I cannot state how much.

Senator Wagner:—How about maternity and child care?

Dr. Robb:—I am not able to answer that phase of it.

Senator Murray:—Your knowledge of the conditions pertains particularly to the big industrial centers?

Dr. Robb:—Yes, sir.

Senator Murray:—Not so much to the rural sections?

Dr. Robb:—I have been president of the state society and president of the local society. I covered the state of Michigan pretty thoroughly for a period of two years when I was president, and I am in contact with that, so that at least at that time I was and have been to some extent and since, and I believe that Michigan has made a good stand in the handling of its problems and they have been difficult ones.

Senator Thomas:—Your program has been in existence since 1921?

Dr. Robb:—Yes, sir, eighteen years.

Senator Thomas:—What states preceded you in such a program?

Dr. Robb:—I don't know of any one.

Senator Thomas:—You do not?

Dr. Robb:—There are twenty-five other states at present doing some type of health education and postgraduate health education.

Senator Thomas:—You are familiar with the interdepartmental social hygiene work right after the war, are you not, Doctor?

Dr. Robb:—I know the name; I do not know its activities.

Senator Thomas:—That was a federal aid project. Would you favor it?

Dr. Robb:—Do you mean in Detroit?

Senator Thomas:—No, in the country.

Dr. Robb:—So far as education is concerned?

Senator Thomas:—So far as health education of a certain type is concerned.

Dr. Robb:—I cannot answer that.

Senator Thomas:—Did it ever force any of its money on a state against its will, do you know?

Dr. Robb:—Not that I know of.

Senator Wagner:—Are you familiar with the experiments going on in Detroit that I have been informed about of treating tuberculous cases?

Dr. Robb:—I know something of their program.

Senator Wagner:—It has been successful up there, hasn't it?

Dr. Robb:—Yes, it has, and it has been a cooperation on the part of the physicians of the local community.

Senator Wagner:—Yes; we want that cooperation, too.

STATEMENT OF DR. WINGATE M. JOHNSON

Dr. Cary:—Mr. Chairman, the next subject which we wish to bring before you we have divided into two parts, thinking that we could cover it better that way. I present Dr. Wingate M. Johnson of Winston-Salem, N. C., a general practitioner from North Carolina.

Dr. Wingate M. Johnson, Winston-Salem, N. C., former president, North Carolina State Medical Society:—Mr. Chair-

man and Members of the Committee: The Wagner bill provides for the appropriation by the federal government, within the next three years, of $158,000,000 "to construct and improve needed" general hospitals in the United States, besides an unlimited amount for hospitals for tuberculosis and mental disease. The bill also requires the states involved to spend approximately an equal amount. Before authorizing such a huge appropriation, the custodians of the people's tax money will, of course, want to be sure that it is needed.

According to the latest statistics available—for 1938—there were 6,166 registered hospitals in the United States, with approximately 1,200,000 beds. Of these beds a daily average of 195,674 were empty. The number of hospital beds occupied for the United States as a whole was 68.9 per cent, varying from 53.6 per cent in Mississippi to 73.3 per cent in Michigan. Furthermore, the proportion of empty beds for 1938 showed a definite increase over 1937.

From 1927 to 1938, while the population of the country was increasing only 8.9 per cent, the number of registered hospital beds increased by 36.1 per cent. The ratio of beds to population increased from 2.9 per cent to 3.3 per cent. During 1938 the growth in registered hospitals added 101 beds for every day in the year, including Sundays and holidays. Before spending the taxpayers' hard-earned money for the wholesale building of new hospitals, would it not be well to wait until we are utilizing those we have? In deciding the question we should remember that the population of our country is rapidly coming to a stationary figure. From early colonial times to 1860, every decade showed an increase in population of more than 30 per cent. In 1860, however, the curve of growth began steadily to flatten. For the decade ending in 1940 we may expect only 7 per cent increase.

Another fact to consider, before we launch on a program for erecting additional tuberculosis hospitals, is that the number of tuberculous patients in the United States is rapidly decreasing. In 1904 there were 280 deaths from the Great White Plague per hundred thousand; in 1937 there were fifty-six—exactly one fifth as many.

It is true that the amount of mental illness in the United States is increasing; but even so hospitals for nervous and mental diseases had 29,485 empty beds in 1938, as compared with 23,710 in 1937. This increase could be explained by two principal reasons: First, these hospitals have grown in number and in capacity far more rapidly than have the general hospitals; second, the dramatic results of insulin and metrazol therapy in dementia praecox and of fever therapy for paresis have shortened the hospital stay of numerous patients.

Likewise in our general hospitals the stay of the average patient is steadily being shortened. Many prolonged diseases such as typhoid fever and dysentery have been virtually exterminated. The acute respiratory diseases which have largely replaced them are of shorter duration. Furthermore, modern medical science has found ways to shorten the duration of many diseases other than mental; for example, serum, x-rays or sulfapyridine for pneumonia. Recent surgical advances have shortened the postoperative periods of many conditions.

The argument oftenest heard is that, while the thickly settled states have ample hospital facilities, those with a high ratio of rural or small town population are really suffering. Last July, during the National Health Conference, a radio program entitled "The Fight Against Death" was broadcast over the NBC network. According to the station announcer it was presented by the United States Public Health Service and the Department of Interior Office of Education. In melodramatic form it told the story of a man slowly dying of cancer. He had "had every doctor in the country," but not one had diagnosed his ailment. Just before the end he was carried in a hearse to a hospital 300 miles away, where the great diagnostician who saw him there had to tell his wife that the poor fellow must die in a few hours of cancer. The play ended with a Voice—presumably from the clouds—saying "Jim need not have died had there been in his state a cancer center where he might have gone for good care."

This cruelly unjust broadcast left the impression on the public that the average doctor is not competent to recognize cancer, that there must be a specially equipped diagnostic center for this purpose, and that hospitals are widely scattered. On the contrary, a recent survey of the American Medical Association showed that less than 2 per cent of the population are more than 30 miles from a registered hospital; and 30 miles on modern hard surface roads now means less than did a mile of dirt road in horse and buggy days.

The consummation so devoutly to be wished, of bringing hospital facilities within the reach of the low income groups, will not be reached by building more hospitals than we need. Rather, to do so would make for greater hospitalization cost. To withdraw some of the patronage from hospitals now in operation would necessarily add to the administrative cost per patient. Again, the expense of building, equipping and maintaining new hospitals would have to be borne by somebody. Instead of using tax money to build superfluous new hospitals, why not use it to pay for the necessary hospitalization of the medically indigent?

Within the past several years, millions of American people have enrolled in voluntary hospital insurance plans to assure themselves of hospital care in time of need. Have those who drafted this proposed legislation considered the effect on their voluntary hospitalization plans that would inevitably follow this proposed bill to become a law? The Wagner health bill makes no promises for safeguarding or encouraging voluntary associations that have long been operating to the benefit of millions of workers in the United States. These voluntary organizations and mutual associations represent a commendable effort on the part of their members to make provisions for assistance to their own members for the use of funds and in many instances maintenance of their own hospitals without the use of governmental funds.

Senator Wagner:—You feel then that there is no need for the development of any new hospitals, that if money is to be expended it should be expended in the way of making it possible for indigent people suffering from disease to be able to avail themselves of the opportunities that are now existing?

Dr. Johnson:—Yes.

Senator Taft:—What is the situation in North Carolina? Is there an ample supply of hospitals?

Dr. Johnson:—Yes, we are adequately supplied with hospitals for the most part.

Senator Murray:—Of course you recognize that in some sections of the country that is not always true?

Dr. Johnson:—It is true that in some of our counties there are no hospitals, but they are within reach of hard surface roads.

Senator Murray:—For instance, in my city of Butte we have hundreds of tuberculous or silicotic patients that were unable to have access to the only institution in the state that undertook to care for that. They were dying on the street as the result of not having adequate hospitalization. That probably is true in a great many sections of the country.

Senator Ellender:—Dr. Johnson, how many hospitals have you in the state of North Carolina that are entirely dependent on or entirely maintained by the state?

Dr. Johnson:—That are entirely maintained by the state?

Senator Ellender:—Yes.

Dr. Johnson:—Two for tuberculosis, two for mental diseases—

Senator Ellender (interposing):—I meant general hospitals.

Dr. Johnson:—We have no general hospitals maintained by the state. We have a number maintained by the towns.

Senator Ellender:—How many have you by counties that are maintained out of public funds?

Dr. Johnson:—We have few if any general hospitals maintained by public funds.

Senator Ellender:—You stated on page 3 of your statement that, instead of using money to build hospitals, the money ought to be used to care of indigents. Just how would you do that, Doctor?

Dr. Johnson:—Certainly, I think that so far as it can be done it should be done by each community as the need arises.

Senator Ellender:—Out of funds raised how?

Dr. Johnson:—Out of funds raised in the local communities.

Senator Ellender:—You would not want the government in any wise to help?

Dr. Johnson:—I think in exceptional instances it might be that way.

Senator Taft:—Would it be part of the general relief program?

Dr. Johnson:—Yes, sir, it would be part of the general relief program.

Senator Taft:—And in which the states of the nation might participate according to the size of the state?

Dr. Johnson:—Yes.

Senator Ellender:—Would you want the presently existing hospitals, that is the private hospitals, paid by some governmental agency whether it be local, state or national, paid the expenses of the inmates who come there for attention?

Dr. Johnson:—Yes, I think that would be far preferable to building federal hospitals and in competition with these private institutions.

Senator Ellender:—Would you know what the cost per person would be, about, in North Carolina?

Dr. Johnson:—Approximately $4 a day; $3.50 to $4 a day.

Senator Ellender:—What service does that include other than the hospital room?

Dr. Johnson:—It includes the hospital room, the general nursing care, the board and the simple medicines.

Senator Ellender:—It would not include medical care?

Dr. Johnson:—It would not include medical care, no, sir.

Senator Wagner:—Doctor, I was interested in your answer that the medical cases in the state ought to be treated just as relief was treated. Is that your idea?

Dr. Johnson:—The indigent medical cases?

Senator Wagner:—Yes.

Dr. Johnson:—Yes.

Senator Wagner:—Just as you provide relief?

Dr. Johnson:—Yes.

Senator Wagner:—Do you mean by the state or the federal government or how?

Dr. Johnson:—By the state if possible. In our state I think we are capable of taking care of our own.

Senator Wagner:—Not by the federal government?

Dr. Johnson:—No.

Senator Thomas:—Do you think your state is able to take care of all the relief in North Carolina?

Dr. Johnson:—Our state pays about five times in federal taxes what it gets back in relief funds.

Senator Murray:—It pays it indirectly though, doesn't it? It is collected from the people out in Montana where I live and people all over the country—

Dr. Johnson (interposing):—Yes, that smoke cigarets.

Senator Ellender:—Out of my state, too. And also in New York, isn't that so, Senator Wagner?

Senator Wagner:—Yes. Then you do need some federal funds for relief, don't you?

Dr. Johnson:—In some sections of the state.

Senator Thomas:—How else would you equalize your returns from federal taxation if you did not get something from the federal government?

Dr. Johnson:—Our people are human enough to take federal money if they can get it, of course.

Senator Thomas:—Are you in favor of cutting out all federal relief from the people of North Carolina, who, you say, pay more taxes than they get from those benefits?

Dr. Johnson:—Not so long as we have to pay those taxes.

Senator Thomas:—Then why do you say that you are in favor of everything coming right from the local community?

Dr. Johnson:—Because the local communities feel the need most and know best how to cope with it.

Senator Taft:—You mean that the primary responsibility is that of the local community, and if they have not got enough resources they can get the money from the state or the federal government if necessary?

Dr. Johnson:—That is the idea.

Senator Murray:—What happens in your state when you have a surgical case where an injured person needs an operation and there is no state or local provision for taking care of those cases?

Dr. Johnson:—In most parts of the state there is.

Senator Murray:—In most parts of the state?

Dr. Johnson:—Yes. I don't know any parts of the state where a patient could not have a necessary operation whether he is able to pay for it or not.

Senator Murray:—Is it not true that frequently people are taken to a hospital and won't be given admission unless the costs are guaranteed in advance, friends have to hustle around the city to secure promises or pledges to take care of the case before it will be accepted?

Dr. Johnson:—That may be true in a few strictly private hospitals.

Senator Murray:—You know of a great many instances of that kind, do you not? You have heard of a great many instances of that kind where an operation was going to cost $250 and the people are absolutely poverty stricken and have no means, and they have to get somebody to come in and agree to pay that money if they are going to be taken care of?

Dr. Johnson:—In thirty years of practice I have not known of one single instance like that to happen in my observation.

Senator Ellender:—What part of North Carolina do you live in?

Dr. Johnson:—Winston-Salem.

Senator Ellender:—That is the tobacco center. You have no poverty there?

Dr. Johnson:—While it is the wealthiest town of the state, the wealth is in the hands of a comparatively few. We have more poor people and more rich people than any other town in the state, but we take care of our poor people.

Senator Ellender:—Do you have a municipally owned hospital there?

Dr. Johnson:—Yes.

Senator Ellender:—Oh, that is the reason. How much does the municipality spend per year to take care of that community?

Dr. Johnson:—I think it will average between $15,000 and $20,000.

Senator Ellender:—How many other cities or counties in your state are there that do have publicly owned hospitals of that kind where they can give service to these indigent people?

Dr. Johnson:—There are quite a number; I could not answer offhand.

Senator Taft:—Is it not true that, as in most states, where there is no publicly owned hospitals there is an appropriation to take care of indigent patients in privately owned hospitals?

Dr. Johnson:—Yes. For instance, in our hospital we take care of a great many patients from adjoining counties which have no hospitals.

Senator Ellender:—Do you know about how much money the state of North Carolina appropriates for that purpose?

Dr. Johnson:—No, I do not.

STATEMENT OF DR. R. LLOYD SENSENICH

Dr. Cary:—Mr. Chairman, I present Dr. Sensenich of South Bend, Ind.

Dr. R. L. Sensenich, South Bend, Ind., member of the Board of Trustees of the American Medical Association:—Mr. Chairman and Gentlemen of the Committee: I should like if I may to submit the material for the record which I have prepared. To save your time, may I briefly touch the high spots?

Senator Murray:—Your statement as prepared will be copied in the record.

Dr. Sensenich:—The American Medical Association in its House of Delegates in session in Chicago in September 1938 took action indicating its approval of the expansion of general hospital facilities where need exists. In fact, the American Medical Association has never opposed and has always encouraged the establishment of hospital facilities of acceptable standards wherever such facilities were needed.

Approval could likewise be given to the purpose of the Wagner Health Bill to the degree that its purpose would be directed to the provision of "needed hospital facilities," as the term hospital is defined in common usage, in areas suffering from severe economic distress, and in rural areas needing hospitals which cannot otherwise be provided. However, examination reveals that, in its provisions, old terms are to be defined with newly designed meanings. The indications of "need" are to be loosely interpreted, tried practices are to be infiltrated with new agencies and undefined working agreements, and federal control is to be obtained through gifts of money derived from taxes. Such methods and the suggestion of undisclosed objectives make approval impossible.

It must be pointed out that "hospital facilities," as used in the action of the House of Delegates, applies to hospital buildings, equipment, nursing staff and necessary personnel, to be available for the treatment of the sick of a given community by qualified physicians who reside and practice in that community. The action of the Delegates did not endorse federal governmental domination of local communities through subsidies obtained from taxes, as to the establishment, policy or management of hospitals for local patients in their respective communities. It should also be clear that the action of the Delegates did not approve of burdensome taxing programs for support of new undefined types of institutions and it did not approve of centralized, bureaucratic control of the medical care of the people by governmental agencies.

The House of Delegates of the American Medical Association on May 17, 1939, took action opposing the Wagner Health Bill (S. 1620) and pointed out certain principles on which it based its opposition. The report of that action is already in your hands.

No formula is proposed in this bill by which needs for increase in hospital facilities shall be determined. "Where need exists" must be recognized as a proper restriction, requiring consideration of scientific and practical factors as well as theoretical and economic indications. It is self evident that the population of a community and average occurrence of types of illness requiring hospital care determine the need for beds. However, hospitals and special equipment for diagnosis and treatment are useless tools without trained physicians. On the other hand, a physician trained in a specialty in medicine would not long retain his skill or usefulness as a specialist in major surgery, diagnostic procedures or other special treatment if diseases requiring such care occur only infrequently in that community. Special hospital equipment does not alter that situation.

The permanence of the hospital project from the standpoint of probable future "needs" and sources of income of the population in relation to existing or proposed facilities is of the great-

est importance. It is self evident that the local community for which the hospital facility is planned and which must later support it should have a major voice in determining its own need and the manner in which it shall be met. The opinions of well informed local citizens concerning needs and maintenance should be given consideration, and general hearings should be held in which citizens may be heard before hospital construction is determined on. This bill makes no provision for such safeguards.

Turning to the report of the Technical Committee on Medical Care to the Interdepartmental Committee to Coordinate Health and Welfare Activities as a probable source of material from which the estimates of needs for hospital facilities used in the preparation of this bill may have been obtained, we find the statement that 1,338 counties of the United States do not contain a registered general hospital. These counties are said to contain about seventeen million people. Although the report admits that many of these counties are not populous, the implication carried is that this number of people are without needed hospital facilities. Without questioning the need of hospitals in some of these 1,338 counties a closer study of the distribution of hospitals reveals that the use of the boundaries of counties as a basis of determining availability of needed hospital facilities is misleading. For example, in the state of Illinois there are twenty-six counties without hospitals, but there is no part of any one of these counties which is not within easy reach of hospitals in neighboring counties. Other studies indicate that there are relatively few population groups of sufficient numbers to justify the provision of hospital facilities who do not have such facilities of acceptable standards reasonable accessible. With good roads and modern transportation the very small hospital is subject to the same influences as have largely eliminated the little red schoolhouse and the small county tuberculosis camp. With the consolidation of these facilities into larger units has come greater elasticity in meeting varying demands, better equipped institutions, better trained personnel and better standards of medical care. Transportation distances are frequently little greater than those necessary in the larger cities, and the patient can be conveyed with less disturbance than in city traffic.

For the foregoing reasons it must be recognized that boundaries of governmental units cannot be used as a measure of hospital needs. Local conditions and distances must be studied in each instance. Likewise the population of a community alone is not a dependable guide to needed general hospital beds, and consideration must be given to varying conditions of housing and group social tendencies which are local in character.

The use of the 5.2 beds per thousand of population in the large city counties or 4.7 per thousand of population estimated in the metropolitan and adjacent areas in 25 per cent of the states as a formula for hospital needs to be applied to the rural areas is not warranted. Not every minor illness can be hospitalized, and the average rural resident, well housed, still prefers to be treated for his less serious illness in his home; whereas, in large cities people who live in small apartments, with other members of the family employed away from home, more frequently go to the hospital for even the slightest disability. Studies by the Council on Medical Education and Hospitals of the American Medical Association show incontrovertibly that many of those areas now having the smallest number of beds in proportion to the population have the largest percentage of empty beds.

The average duration of stay in hospital per patient has declined steadily for some time. As a result, existing hospitals may now care for a greater number of patients per year without increase in the number of beds. Since 1931 the average duration of a patient's stay in a general hospital has been reduced from 14.3 to 12.5 days. This represents a reduction of 12.5 per cent, or one eighth, in the time spent in the hospital. Such a decrease in the average stay obviously permits a larger number of patients to be cared for with the same physical facilities. If there had been no reduction in the length of stay of the average patient in general hospitals in 1938, 60,000 empty beds would have been filled. One cannot predict what further reductions may be made in the average duration of the patient's stay in the hospital, but progress in medical science continuously tends to shorten periods of hospitalization. Recent advances in the treatment of pneumonia and other infectious diseases should be reflected in a further reduction in the average hospital stay.

The bill authorized the appropriation in three successive years of 8, 50 and 100 million dollars respectively for the purpose of constructing and improving general hospitals. Under sections 1202, 1203 and 1204, financial participation by the states is required. The extent of this participation will probably vary from state to state, but assuming that on the whole the contributions of the federal government will be on a fifty-fifty basis [1] there will be available for the construction and improvement of government-owned general hospitals, in the fiscal year ending June 30, 1940, $16,000,000, in 1941, $100,000,000, and in 1942, $200,000,000. Taking $4,000 [2] as the average cost per bed of general hospitals, it would seem that this bill makes provision for the addition of 4,000 general hospital beds in 1940, 25,000 general hospital beds in 1941 and 50,000 general hospital beds in 1942. The 79,000 beds which may be added under the provisions of this bill relate only to government-owned hospitals and do not include such enterprises, public or private, as may be undertaken without the stimulus of a federal subsidy. A recent study indicates that there are now 349 hospitals under construction or projected, without federal subsidy.

From the chart it will be seen that over the eleven year period 1928-1938 inclusive the average rate of increase in the number of beds in general hospitals was 1.9 per cent. The increases proposed in the Wagner bill amount to a total of 79,000 beds, 16.2 per cent in three years, or an average rate of increase of 5.4 per cent.

In 1938 the general hospitals of the country were filled to 68.9 per cent of their capacity; 31.1 per cent of the beds were unused.

If the addition of hospital beds alone is proposed, the wisdom of a threefold multiplication of the normal rate of hospital facilities should be seriously questioned.

Tuberculosis hospitals differ from general hospitals in that, as tuberculosis is a transmissible disease, isolation and training of the patient for the safety of others is of importance. The course of the disease is chronic and periods of hospitalization are longer. However, progress in surgical treatment of tuberculosis has very greatly reduced the average period of needed hospital care. Institutions receiving only early cases have been able to reduce their average stay per patient from a year or more to a few months. Institutions for the treatment of tuberculosis are, as a consequence, able to care for more patients per year in proportion to the total number of beds than ever before. The shorter periods of hospitalization depend to a great extent on early recognition of the existence of tuberculosis and therefore early treatment. This is accomplished by education of the public and not primarily by the existence of hospitals. Tuberculosis hospitals are needed in some areas but hospitals without coordinated educational efforts are ineffective.

Small county institutions cannot readily provide facilities or medical men skilled in modern surgical treatment of tuberculosis. Later tendencies have been to the erection of larger institutions functioning as district hospitals although owned by large populous counties or by the states. Modern roads and transportation have removed all justification for the small local boarding-house type of tuberculosis hospital. The ratio of beds needed depends on local conditions and the educational possibilities of the community. The rapid reduction in the number of cases of tuberculosis has made any need of great hospital expansion in the major number of the states improbable. The per diem cost of maintenance is influenced by local conditions.

Hospitalization of mental patients presents requirements differing from those of the general hospital because of the factor of necessary custodial care of patients, the predominance of cases running a chronic course, and the high percentage of incurables. Admissions have increased but progress has been made in reducing the average period of hospitalization. Recent advances in treatment of some types of mental diseases may be reflected in still shorter periods of confinement to institutions.

Experimental studies are being made in caring for certain early cases of selected types of mental disorder, presumably curable, in general hospitals to avoid confinement to hospitals designated for the insane. Nothing should be done by governmental agencies to discourage these efforts.

A special survey by the American Medical Association reported in 1936 the overcrowded condition of existing institutions and stressed the need for expansion of facilities. However, there has been much building since then, and reports indicate nearly 6,000 more empty beds in mental hospitals in 1938 than in 1937. The per diem cost depends on local conditions and kind of cases treated.

Section 1202 of title XII of the bill provides that the allotment of funds shall be determined in accordance with rules and regulations prescribed by the Surgeon General of the Public Health Service with the approval of the Secretary of the Treasury. Consideration of (1) the needed additional hospitals, and (2) the financial resources is required. Time will be required for investigation after such regulations have been prescribed, in the event this bill should pass.

Studies made by the American Medical Association indicate that the need for additional hospital facilities has been greatly

1. National Health Conference, July 18, 19, 20, 1938, p. 39, line 21.
2. National Health Conference, p. 39, line 6. The Interdepartmental Committee uses $3,500 as the average cost per general hospital bed.

overestimated, the lack of medical care overcolored and the proposed expenditures extravagant. There is also much reason to doubt that reasonably proved needs could be found and any substantial portion of the proposed appropriations be wisely expended in the time proposed in this bill. A rapid widespread construction program without sufficient study would be inexcusable. Too great dislocation of normal production of special and technical hospital equipment should be avoided. A shortage of trained hospital personnel must be considered. The effect of introduction of central federal control of policies of purely local hospital facilities through control of subsidies might readily outweigh any benefits to be derived from contributions of federal funds.

It is not clear whether the government under this bill proposes to assume responsibility for an indefinite period for aid in the care of all tuberculous patients and those suffering from mental disease. However, if need for federal assistance in certain communities should be established, the per diem payments should be made on certification by properly constituted authority as to the number of patients treated who were eligible for treatment. Such reports would then be subject to examination and audit by the federal government. Major governmental machinery or federal domination of local administration is not justified.

Hospitals for treatment of the tuberculous have a record of outstanding achievement in assisting in the reduction of sickness and death from tuberculosis. They have associations which provide opportunity for interchange of information developed in scientific research and experience in management and operation of these special hospitals. It is improbable that they would feel the need of federal governmental interference in already well functioning institutions. This interference would be especially objectionable in that the federal agency would secure domination by acquiring control of funds now available to the institution from taxes. States financially sound and with adequate facilities would be forced to accept subsidies and federal domination in order to secure return of any part of the pooled federal funds to which they would be forced to contribute heavily in taxes.

Senator Ellender:—You do not find any language in this bill that would give the federal government that right that you have just mentioned, do you, Doctor?

Dr. Sensenich:—It is not a right, sir; I did not say it was a right. It is what the state would have to do to get any return on its taxes. There would be stimulation to the state from the standpoint of saying that you may have a subsidy if you match it with taxes.

Will you pardon me until I finish, and then ask me that? I do not mean to be discourteous, but I am sure that you understand and I think that what follows will answer that.

Senator Ellender:—That is all right; I understand perfectly.

Dr. Sensenich:—Control of management and personnel and domination of policies of existing institutions in this manner would be secured by capitalizing on the need of the few.

The required submission of plans by each local community which might seek to avail itself of the vague provisions of this bill leave much to the executive action of those who administer it. Therefore, the best interests of the public require proper qualifications by training and experience of those who would administer or advise in the provisions of this bill, having to do with the facilities for medical care.

It is not required in the bill that any executive concerned in the administration of the proposed act shall have had experience in these matters involved in the actual delivery of medical service. The Surgeon General of the Public Health Service, who is named as administrator, is primarily concerned along lines of general health service not directed to treatment of the individual. Although that official might be specially trained and an outstanding administrator of the Public Health Service, he may have had little contact with hospitals and no experience in the practice of curative medicine. Interest and experience along the lines contemplated in this bill might vary greatly between different incumbents of that office.

The Surgeon General of the Public Health Service is authorized in the bill to establish an advisory council or councils. No statement is made as to the manner of selection of the members of this group. The bill likewise fails to invest this body with any authority or indicate that its recommendations need be considered by the Surgeon General in the administration of the act. Depending on the qualifications of its members, such a group might be helpful to the Surgeon General by the contribution of information based on experience or it might be organized and used for the purpose of overcoming resistance to plans believed by the medical profession to be detrimental to standards of work and the best interests of the public.

State plans on which allotments are to be made by the Surgeon General of the Public Health Service are required to provide for "state agencies" of vague description but with authority to make and publish rules and regulations, which have the effect of law. They are to be advised by advisory councils of uncertain qualifications and influence. Through working agreements with agencies concerned with welfare, assistance, social insurance, workmen's compensation, labor, industrial hygiene, education or medical care, governmental control may extend into the most intimate personal matters of labor, welfare and medical care of each individual.

It would seem unlikely that a surgeon general of the Public Health Service would wish to have the responsibility for the administration of such an indefinite and all inclusive act; at any rate, the enactment of such a law would be contrary to public policy.

The federal government should have no part in the program of any needed expansion of hospital facilities other than that any allotment of funds should be honestly expended in the erection of the hospital facilities according to local and state plans previously agreed on. Federal payments in maintenance where needed should be made on certification by a legally constituted authority that service has been provided for certain individuals eligible for such treatment. The government should have the right to make necessary examinations and audits to determine the correctness of those accounts. However, the federal government should have no authority to dominate the policies or personnel of the hospitals or to make working agreements binding the community directly or indirectly in the operation of its hospitals. No extensive plan is needed.

From the definition of the term hospital as used in the title, "includes health, diagnostic and treatment centers, institutions and related facilities," it is evident that more is contemplated under the proposed legislation than is ordinarily included under the term of hospitals. Otherwise there would be no reason for introducing this vague and all inclusive definition. It is noted that the Technical Committee in its report proposed the construction of 500 health and diagnostic clinics in areas in which the individual does not have convenient access to hospitals.

A plan for the establishment of clinics for the diagnosis and treatment of ambulant patients in areas already supplied with physicians should be weighed carefully from the standpoint of the ultimate best medical service to the community as a whole. If the clinic contemplated would encourage the patient to present himself directly to the clinic for examination and treatment, it would not offer anything superior to dispensary service. The latter type of service lacks needed medical history of other illnesses and treatment, and opportunity for observation. This tends to detachment of interest, and the responsibility of the medical staff member to the patient is soon replaced by responsibility only to the system which employs him. There is reason to believe that the service would not be superior to that offered by physicians in the community.

Such a clinic is an outgrowth of the view entertained by some that Medicine can be "depersonalized"—that the physical man can be treated without intimate knowledge as to his emotional stresses and the effects of his contact with his environment.

The establishment of clinics for treatment of ambulant patients only assumes further that the individual may have one physician for illnesses in which he is ambulant and another when he is confined, without loss of values which are of importance in the best medical service. Obviously these are faulty assumptions.

It must be recognized that the private physician will still be necessary to attend patients who are not able to go to the clinic. The well trained private physician, with a closer and more personalized service to the individual and his family in their home, will give good medical service to more people. He should be given every opportunity and assistance to increase his usefulness, and governmental machinery should not be permitted to impair it. The operation of large diagnostic and treatment clinics recently established in very populous centers of impoverished people cannot be fully evaluated on so brief experience. Obviously, it cannot be translated into terms of small rural areas.

If the establishment of new types of institutions is contemplated, this should be omitted from the proposed effort to improve hospitalization facilities. Such plans should be left for consideration after time for a longer observation of existing units and of study of needs, if any remain, after needed expansion of hospital facilities has been accomplished.

The government may enter directly into the medical care of the individual under the provision for "working agreements"

between the state health agency and "any public agency" administering related services "including welfare, assistance, social insurance, workmen's compensation, labor, industrial hygiene, education or medical care," as provided in paragraph 9 of section 1203. Studies and demonstrations of undefined character are provided for under section 1208 of this title. It is clear that this bill, which permits control of the medical care of the individual by undefined governmental agencies given authority to impose regulations and enforce compliance by control of tax funds, is not in the best interests of the public and should not be enacted.

The bill specifies that funds will be allotted only to provide hospital facilities to be owned by the state or its political subdivisions. This provision might destroy many existing church hospitals, community general hospitals and other hospitals which have given us the best hospital service in the world.

Emphasis was placed by the House of Delegates in the meeting of September 1938 on the following: "The hospital situation would indicate that there is at present greater need for the use of existing hospital facilities than for additional hospitals." It was further suggested that "the stability and efficiency of many existing church and voluntary hospitals could be assured by the payment to them of the costs of the necessary hospitalization of the medically indigent."

Existing hospitals, in some instances as old as the nation, have not only provided facilities of the highest standard but in many instances have carried an excessive load of indigent patients, this because governmental agencies have not accepted proper responsibility and have not assumed the financial support of those individuals for whom there was no other provision.

Many of these hospitals, if paid adequately for indigent care by relief authorities, could have given greater service to the community with possible increased occupancy of now vacant beds.

No provision is made in the bill under consideration whereby any nongovernmental charitable hospital could be given aid in making improvements or extensions of present hospital facilities.

It must be recognized that hospitals, like other institutions, can operate at a maximum effectiveness and minimum per diem costs at a certain optimal bed capacity. Many smaller hospitals could be stabilized and improved in point of service if they were assisted financially in caring for indigents. They might then apply their resources to enlargement to an optimal size, provided prospective occupancy warrants.

Duplication of existing institutions by new government hospitals, each with its investment for heating plants and other utilities when one installation would suffice, duplication of buildings for housing personnel, administrative offices and public space, duplication of costs throughout, when only a limited expansion of bed capacity may be required to meet community needs, is not sound economic practice. Yet that is the situation that this bill may create.

It has not been proved that government owned hospitals have had better management or provided better service than other hospitals. In fact, there is much reason to believe that, in the main, church owned hospitals and community hospitals have provided better management, higher standards and more satisfactory service than government owned hospitals.

Community hospitals belong to the public in point of service and in actual ownership, as do government owned hospitals, but have the advantage of altruistic interest and direction by the best citizenship, continuity of policy, and freedom from political interference. Church owned hospitals belong to the people in point of service if not in actual ownership. They are created and maintained on the basis of gifts from public spirited citizens and thousands of small contributors and are the expression of the interest and support of the public. Community hospitals and church hospitals constitute the major portion of the total number of hospitals of the United States and represent an investment of billions of dollars made before the government became interested to any great extent in the hospital care of the sick. They should not be sacrificed to permit the disservice to the public proposed in this bill.

However, church owned or community hospitals with long histories of medical work of high standard and recognized public service would not accept the federal domination evidence in the provisions of the Wagner Health Bill. Present high standards of hospital administration and scientific care have been attained by mutual cooperation with the organized medical profession and acceptance of high ideals and not by government assistance, regulation or example. Acceptance of the provisions of this bill would make present high standards and grading subservient to government regulation. A record of high grade performance in the past is more dependable assurance of high grade service in the future under the continued mutual efforts of religious organizations and interested unselfish local residents and the medical profession than any pattern which the government will provide. The lively, unselfish interest of local citizens is assurance of a better merit system than policies and management imposed by a distant federal administration or by partisan politics.

Despite the history of outstanding public service of community and church owned hospitals, it is indisputable that the administration of this proposed act might make it impossible for these hospitals to finance improvements or expansion because an allotment from public funds may be offered to the local community only on condition that a new government institution be built. Government contribution toward maintenance would make such new institutions destructive competitors against older hospitals of high standards, such as have helped to make the hospital pattern of the United States the envy of the rest of the world.

It would seem to be a strange concept of the function of government to stimulate states to submit plans detrimental to community institutions of the highest standards and of the most unselfish service in order that the state might receive a partial return of heavy and burdensome federal taxes which had been accumulated in a federal pool. Under this bill each state would be encouraged to prepare plans and levy additional local taxes in order that it might participate in the pool and prevent distribution to other states of funds which it is annually forced to contribute in federal taxes. Acceptance of federal domination accompanies acceptance of federal subsidies. For this reason as well as others previously stated the Wagner Health Bill S. 1620 is not in the best interests of the public and is opposed.

Senator Ellender:—Doctor, with reference to the question that I propounded to you a while ago, you fear that, because the federal government will let certain communities have money under this bill, eventually the government might dominate them. That is the language used?

Dr. Sensenich:—Senator, may I read to you from the bill?

Senator Ellender:—That is what I wanted you to point out to the committee. I would like you to point out any language in this bill to show that the federal government would be in charge of the health service, let us say, the hospital services in the states.

Dr. Sensenich:—May I refer to section 1203-A on page 27, beginning with:

A state plan to effectuate the purposes of this title, submitted in respect to either clause (1) or clause (2) of section 1201, both shall (1) provide for financial participation by the state; (2) provide for the administration of the plan by the state health agency or for the supervision by the state agency of any part of the plan administered by another state agency or by a political subdivision of the state.

And then, without taking the time to read it out loud, on the opposite page provides such methods of administration as are

found by the Surgeon General of the Public Health Service to be necessary for the efficient operation of the plan, including: Methods relating to the establishment and maintenance of personnel standards on a merit basis; and methods of establishing and maintaining standards for institutional management and remuneration for such management, such methods to be prescribed by the state agency after consultation with such professional advisory committees as the state agency may establish.

Now, this is outside of hospitals. This is the state agency. No one locally there is consulted.

Then further on the same page it is provided:

(6) Provide a system of financial support which will give reasonable assurance of continuing maintenance of added hospitals and of their potential availability to all groups of the population in the designated area subject only to the suitability of the hospitals for particular diseases and conditions and to the financial arrangements for payment for service.

Senator Ellender:—All of that refers to what a state must do in order to obtain the funds?

Dr. Sensenich:—That is right.

Senator Ellender:—But what I had in mind was, after the funds were given, and after the hospitals are built, shall be some language there that would lead you to believe that these hospitals will be managed by the federal government and the states shall lose control?

Dr. Sensenich:—The federal government then maintains the facilities on a partial basis for three years; all of it the first year, two thirds the second year and one third the third year. Each time these budgets have to be approved—if you will turn to the latter part of the bill you will find under section 1205 on page 32:

Whenever the Surgeon General of the Public Health Service finds, after reasonable notice and opportunity for hearing to the state agency administrating or supervising the administration of any state plan approved under this title, that in the effectuation or administration of such plan their failure to comply substantially with any requirement of subsection 1203, he shall notify such state agency that further payments will not be made to the state until he is satisfied that there is no longer any such failure to comply. Until he is so satisfied he shall make no further certification to the Secretary of the Treasury with respect to such state.

Senator Ellender:—That is correct. In other words, the bill lays down what ought to be done.

Dr. Sensenich:—What must be done.

Senator Ellender:—What must be done if you want to put it that way. The same principle applies to our road building; the government furnishes a couple of hundred million dollars to the states each year; all they do is to give plans and specifications.

Dr. Sensenich:—That is right.

Senator Ellender:—as to how the roads shall be built.

Dr. Sensenich:—That is right.

Senator Ellender:—And that is all. And what the government is interested in is that the money is spent according to the aspects laid down by the plans and specifications.

Dr. Sensenich:—Why don't you do the same thing to the hospitals then, if they are built according to the plans and specifications, then you discontinue?

Senator Ellender:—That is what this bill intends to do.

Dr. Sensenich:—I don't think it does.

Senator Ellender:—I refer you to page 7 of your statement in which you criticize the bill in this wise. You say:

> The Surgeon General of the Public Health Service is authorized in the bill to establish an advisory council or councils.

No mention is made as to the manner of selection of the members of this group. The bill likewise says to "invest this body with any authority or indicate that its recommendations need be considered by the Surgeon General in the administration of the act." Now, if we were to adopt your method, we might have government control and that is why the authors of this bill have refrained from giving such authority as you propose to give.

Dr. Sensenich:—I am sorry that I did not make it clear, because I am opposed to this for the simple reason that I do not think that setup is responsible as it is. I do not think that the government should take part in it except to see that its money is well expended. It should not be interested in the operation.

Senator Ellender:—That is exactly what I am sure most of the members of this committee are interested in. Under no conditions would I vote if I thought the federal government could go down into Louisiana, Mississippi or New York and take charge of the hospitals of that state because forsooth they gave a few dollars toward their upkeep—

Dr. Sensenich (interposing):—But that is in the bill, Senator.

Senator Ellender:—If it is I want to strike it out. I would like to have the American Medical Association take this bill and point out every part of it that will lead to that conclusion. If it is in, we want to strike it out and amend it so as to make it doubly sure that under no conditions will the federal government take possession or even have anything to do with the hospital except to see that certain plans and specifications that are made are carried out in order to get the money.

Dr. Sensenich:—Senator, two of the hospital associations, and I am saying this as it was given me not in confidence but in discussion, have already reviewed the bill independently, and they finally abandoned amending it, as I understand for the reason that they each compiled a list of about fifty amendments.

Senator Wagner:—I understood the hospital associations were going to appear here and favor this legislation. I do not think you should say that to the committee unless you are ready to give the names.

Senator Taft:—I understand they have various amendments; that is all the doctor says.

Dr. Sensenich:—That is all they say. That was in answer to your question in an effort to know whether the bill could be amended.

Senator Ellender:—Certainly it is open to amendment, and that is what I suggested as a member of this committee to Dr. Booth when he appeared here several weeks ago to work out a plan. We want to make it simple so that the federal government will not be able to dip down into our state and because they are giving this little ante, as it were, take charge. Now, let me ask you this: The federal government has been spending quite a lot of money through the Public Health Service?

Dr. Sensenich:—Yes.

Senator Ellender:—Have they taken charge in the states?

Dr. Sensenich:—That has to do with education. The Public Health Service has not done any treatment.

Senator Ellender:—But still they spend a lot of money in cooperation with all public servants in the states. For instance, they furnish some to Louisiana, to your state and to other states in order to carry on this education work which you say is being carried on.

Dr. Sensenich:—I know in many instances work is composed largely of work which does not strictly involve the individual. You may take educational work or leave it but, when you take control of the treatment, that is quite a serious matter.

Senator Ellender:—Do you know of any instances where the state health officer is under federal control?

Dr. Sensenich: I would not say that that was a fair designation. I am not familiar with that because it comes down through the state health officer. Whether he is controlled or not, I do not know.

Senator Taft:—What occurs to me is that the Surgeon General has to approve the methods relating to the establishment and maintenance of personnel standards; he has to approve methods of establishing and maintaining standards for institutional management. It seems to me that those powers are so broad that they would have to be set out in rather general language, and then when he came to see whether the hospital was actually complying he would almost have power to tell the hospital what to do in every feature of management.

Dr. Sensenich:—That is true.

Senator Taft:—It seems to me that your criticism of the language on page 28 as being too broad certainly is justified. It could be made very much more definite and less broad, I should think, without changing the fundamentals of the bill.

Senator Ellender:—Those were the suggestions, Senator Taft, that I was asking for, and if there is any doubt about that, if any language can be placed into this bill to make it certain that the federal government—it was not intended that the federal government should do that. I for one would not vote for a bill that did not have it specifically placed in there that they should not have any such control.

Senator Wagner:—Doctor, I agree with what has been said here that nothing ought to be in this bill and I am sure that nothing is in this bill that in any way controls the administration of these hospitals. But the provision that is referred to here—let me ask you in the first place if the federal government grants money for a specific purpose don't you think it ought to have some sort of standards to make sure that the money is not diverted for some other purpose but that it is to be used for the purposes for which it was granted?

Dr. Sensenich:—That was the point that I made, Senator Wagner, that, after all, the government should be interested in knowing that the money that it gave was expended in the manner agreed on and for which it was received.

Senator Wagner:—Yes.

Dr. Sensenich:—But the maintenance and the installation are two quite different things.

Senator Wagner:—Let us develop that for a moment. You do agree that there ought to be some sort of standards set by the federal government to see that the money is expended for the purposes for which it is given?

Dr. Sensenich:—In construction, Senator Wagner, but I would stop at that. I would trust the maintenance of the hospital to the Sisters of the Holy Cross or any one of a thousand local citizens as well as to some distant governmental director.

Senator Wagner:—Are you a believer in the civil service system?

Dr. Sensenich:—Again I will have to decline that.

Senator Wagner:—I am not talking about the appointment of a doctor, but generally speaking.

Dr. Sensenich:—You mean examination for fitness for a place?

Senator Wagner:—Yes.

Senator Ellender:—The merit system.

Senator Wagner: Don't you believe that the federal government believes that there ought to be a merit system that they should at least say that if you are going to administer our money, that those in the state should at least be appointed according to merit and not politics?

Dr. Sensenich:—Certainly according to merit, but may I finish my answer?

Senator Wagner:—Yes.

Dr. Sensenich:—But after all, I should rather depend on the local community in establishing and in effecting a better merit system than a federal administrator.

Senator Murray:—Should not the local community be bound by some standards? Could we not set up standards that apply to the whole country which might be followed throughout the country?

Dr. Sensenich:—I do not believe that that would be possible, for any human agency in one central portion of the United States to lay down a pattern that would be applicable to all of the districts in the United States.

Senator Murray:—Is that not what the hospital associations do, seek to improve the service of the hospitals and to aid them in establishing high standards of operation?

Dr. Sensenich:—Mutually, yes, but that does not mean that they say that this is a fixed pattern for every part of the country.

One community has vastly different social ideas, has vastly different things that do enter into it.

Senator Wagner:—This is not socializing; it is a question of having fit persons to administer the funds. This is not new at all. And may I say to you, Doctor, that I certainly would never vote for a bill which did not provide some sort of standard that the money was not going to be squandered and that a lot of political appointees were going to administer these funds. So we have provided in every case where we have given grants to states some standards of this kind. I recall that, early in my days here in the Senate, we passed an act which was known as the Employment Exchange Bill. Every state now takes advantage of that. It is a coordinated system between the state and the federal government in which the state operates exclusively its employment exchanges and the federal government matches up to a certain sum, depending on the generosity of Congress the funds of the state for the administration of that state, and in return for that certain services are rendered to the federal government. In that law is a provision that the appointments are to be made according to the civil service standards, because what we wanted to be sure of was that in these localities some political fellows who had no test of competence are not placed in charge and the money wasted. It is perfectly proper, and Congress would not have passed that bill without those standards. They were developed in the committee hearings. You take the United States Housing Administration that only provides for loans. That was originated in this committee itself. We wanted to be sure that there would be no labor exploitation, and in that bill there were standards set up—and that was only a loan—and it says "You cannot get this loan if you do not pay the prevailing rate of wage." Under your theory you would say that is an interference with local administration, but we are simply setting standards that the federal money is not to be used for exploitation of people, and so we have set those standards, and you will find in every statute where there is this grant in aid, there are certain standards. Beyond that I challenge you to find a single case where the federal government interferes with the administration by the state. That is all that we want to do here, and beyond that there certainly is no intent here to give any control in the administration of the hospitals to the federal government, and if it is, I agree with the members of the committee who have expressed themselves on that subject.

Senator Ellender:—Senator Wagner, in connection with that statement, I suppose you will welcome amendments to clarify the language if clarification be needed in that regard?

Senator Wagner:—Absolutely. I have been saying right along, and I am surprised that there has not been more specific criticism, because at the last hearing Dr. Booth said to Senator Ellender that undoubtedly the medical association would be glad to cooperate and undoubtedly would have some amendments to propose, and now we hear criticism but no suggestions, and I, like any other member of the committee, would like to have suggestions of those who ought to guide us in this thing, and that is the medical profession.

Dr. Sensenich:—I am sure that the two of us have the same thing in mind when talking about fitness and proper operation, but one is dealing with a little different situation when dealing with a medical matter than one is with most others, and if one were to apply the same civil service examinations to the positions as managers of these hospitals, or even further, if the bill went further and went into the development of diagnostic clinics—I know in a general way what that pattern is—I don't know what the institutions are that are spoken of which might fall within the definitions of this bill; but it is perfectly possible for the man who writes the best examination paper in the world to be the poorest doctor that you or I or any one else wouldn't want to trust his life with.

Senator Wagner:—This does not mean that the federal authorities make up the examination lists.

Dr. Sensenich:—I understand, but it is the method I am talking about.

Senator Wagner:—A moment ago one of the other witnesses complained because it was not a man familiar with the medical profession that was doing this prescribing. Now, we have the Surgeon General of the Public Health Service, Dr. Parran. I don't know anybody more competent. Do you?

Dr. Sensenich:—I know Dr. Parran very well, and I have the greatest respect for him—

Senator Wagner (interposing):—Do you trust him on that?

Dr. Sensenich:—May I finish?

Senator Wagner:—Yes.

Dr. Sensenich:—I don't know any one I have more respect for as a public health officer, and I am discussing Dr. Parran in connection with this bill; but that is not that experience with hospitals or the care of the sick is necessarily for the assignment of the Surgeon General. Furthermore, you are speaking of a bill which is going to operate for some time.

Senator Wagner:—Have you a suggestion which will make it more practical?

Dr. Sensenich:—I have no experience in drafting bills.

Senator Wagner:—What is your idea?

Dr. Sensenich:—I would say that the American Medical Association made its suggestions which it presented this morning in the action taken by the House of Delegates at the St. Louis meeting that this elaborate machinery be not set up, that there is no need for it, that it be established on a need basis.

Senator Wagner:—How?

Dr. Sensenich:—Have some existing agency or create an agency or board of some kind or character to pass on the need and see that your money is well spent on the supplying of facilities where they are needed, and then let the local community take care of it, because it will do a better job than you or I at some distance from it.

Senator Ellender:—What are you going to do, Doctor, where the local community has not got the money?

Dr. Sensenich:—I said if the need exists, to build it, but to be satisfied to step out, and if the local community cannot maintain it and the state cannot maintain it, I don't know any other way that you can do except with federal funds. We are in sympathy with the objective; we have not opposed that but we object to the method because we think that it is not right.

Senator Ellender:—Would it improve the bill if we should write into it, let us say, that on this Professional Advisory Committee, that the medical profession of the state shall have the right or have some say so about the appointment of this board?

Dr. Sensenich:—There are still these broad constructions in the bill which—It would not be safe.

Senator Ellender:—I am talking about that particularly. I am talking about that particular phase of it. Let us see if we cannot get on some common ground as to that phase of it.

Dr. Sensenich:—I am sorry, but what particular phase do you mean?

Senator Ellender:—In preparing plans and specifications and things like that that you mentioned in this discussion.

Dr. Sensenich:—The need is the serious matter.

Senator Ellender:—The what?

Dr. Sensenich:—The determination of the need is the serious matter.

Senator Ellender:—Who is going to determine that? Who should have that authority, in that bill? Whom would you suggest as authority on that, let us say, in the state of Mississippi?

Dr. Sensenich:—The suggestion was that, if you have no existing agency here, you create an agency which would pass on the need, and that an appropriation be made the same as it is made in any other state in the event of need.

Senator Ellender:—If you do not want to deal with Mississippi, let us deal with your state. What kind of agency would you suggest in your state that should do the work?

Dr. Sensenich:—In the first place, there would need be no agency in my state unless it had need. That is the point.

Senator Ellender:—Let us assume that you are a rich state that gets a lot of your funds from poor Louisiana and poor Mississippi and poor Montana, and you are getting oil and sulfur and salt and everything that we have got down there. Let us just forget that you are from Indiana—that is your state?

Dr. Sensenich:—Yes, Indiana.

Senator Ellender:—And that you are living in Louisiana, a rich state, wherein we have a lot of oil and we have a lot of salt, we have a lot of natural resources, but unfortunately the profits that are derived from these natural resources are not available to the people of the state. They were too poor years ago to develop them. Capital from the Northeast came down there and took possession. They are getting millions of dollars from our state today, they are getting millions of dollars from the state of Texas, and because of that those states are now unable to provide adequately for the indigent. Now, assume you are living down there and you are a doctor; what board would you suggest or what kind of a board would you suggest would be competent to pass on the needs of the community of that kind?

Dr. Sensenich:—I should be in favor of permitting the state to set up a board to represent it, but—

Senator Ellender (interposing):—This bill provides that.

Dr. Sensenich:—All right, but it gives the board, that committee, that state agency, much too much power because it sets up vast machinery.

Senator Ellender:—How would you limit it?

Dr. Sensenich:—The only purpose of that board would be the determination of the need, the same as the central board determines need, and if this community needs the hospital, and I understand that that was the suggestion made, and it is determined jointly by the federal government and the local state agency that the need exists here, and the government says "It will take $100,000; we will give that $100,000, the government will advance that money if it is not locally available"—we are saying now it is the need—"and that building is constructed" —now then for that purpose the government has no real reason to enter into this indefinite control any more than when it aids another state in the case of a hurricane; you don't go down and say "Plant so many trees" or "Do this" or "Do that in connection with rehabilitation." We will assume that in the average community they will do quite a good job of managing their own institution if you help them to obtain it. I am trying to make myself clear without telling you what kind of legislation, because after all, that is out of my province.

Senator Ellender:—From what you have just said, we are not far apart.

Dr. Sensenich:—I think that is right.

Senator Ellender:—We are not far apart, because as I interpret this bill it is to be given to those communities who are actually in need, and that is determined how? By equalizing things. Some needs may be such that the state may get but one third of whatever they may ask for, whereas others may get two thirds from the government—don't you see?

Dr. Sensenich:—Yes.

Senator Ellender:—What will determine that will be the need of that community.

Dr. Sensenich:—But do not set up big machinery which induces New York and Indiana and some other states to ask—

Senator Ellender (interposing):—You could not draft an act that would eliminate any community.

Dr. Sensenich:—It is not necessary.

Senator Ellender:—We have to write a formula.

Dr. Sensenich:—That is right.

Senator Ellender:—And if the states comply with it or if they show that they come within that formula or within the yardstick written into this bill, of course they get a share of the money but otherwise they do not.

Dr. Sensenich:—Then let us eliminate all of the massive machinery—

Senator Ellender (interposing):—Which massive machinery?

Dr. Sensenich:—I mean that set up here of institutions and hospitals and diagnostic and treatment clinics and a lot of things that I don't know what they mean, nor does anybody else, and say to any state—you can go to New York and say "You need diagnostic clinics or you need something else." It does not necessarily have to be the need of the little rural hospital that you and I are talking about at the moment, but it can be something else, some new step or some new suggestion or some new ideology as to how the thing shall be taken care of.

Senator Wagner:—The federal government does not go to the state and say "You need that." The state comes to Washington.

Dr. Sensenich:—They have a way of suggesting it—not the government itself, but the officials.

Senator Wagner:—There is a need test right in the bill.

Dr. Sensenich:—Yes, but turn to the definition of hospitals, Senator Wagner.

Senator Wagner:—To get the federal money, you have to show the need.

Dr. Sensenich:—Yes, but look at "hospitals." You and I are thinking about the ordinary hospitals.

Senator Ellender:—What page is that?

Dr. Sensenich:—Page 34; the definition of hospitals according to the bill is as follows: "The term 'hospital,' when used in this title, includes health, diagnostic and treatment centers, institutions and related facilities." I don't know what they are, but I suspect.

Senator Ellender:—How would you define that?

Dr. Sensenich:—I think that the term "hospital" is quite clearly understood throughout a great many thousands of years, and I think that is sufficient. Let us call it a hospital, as it is, and not define it in some new terms.

Senator Murray:—What is a hospital?

Dr. Sensenich:—A diagnostic clinic is something in which a patient does not reside ordinarily. An institution may cover anything—I don't know what.

Senator Murray:—You would relate it strictly to an institution then where people are taken for treatment during a period of their illness?

Dr. Sensenich:—In the generally accepted manner in which the term "hospital" is applied.

Senator Ellender:—Would you furnish us the definition of a hospital that you want to cover by this bill?

Dr. Sensenich:—I would have to get it out of the dictionary; I don't know any other place for the definition of the word "hospital."

Senator Murray:—But people are taken to hospitals for the purpose of having their conditions diagnosed?

Dr. Sensenich:—That is right.

Senator Murray:—So it is a diagnostic place?

Dr. Sensenich:—May I interrupt? A diagnostic clinic, I think, comes from the report of the National Health Conference in which they suggest the creation of 500 diagnostic and treatment clinics which are quite outside the ordinary definition, so there are things in here that I think have been prompted by that study.

Senator Wagner:—If the criticism that you made would be met, would you favor the bill?

Dr. Sensenich:—Senator Wagner, there is nothing personal in this, but I think that you could have done a better job.

Senator Wagner:—What is that?

Dr. Sensenich:—There is nothing personal in this, but I think that you could have done a better job.

Senator Wagner:—I am not saying that; you do not offend me. I think I understand some of the opposition, but I asked you this: Supposing these corrections were made that you are talking about, would you favor the bill?

Dr. Sensenich:—I could not limit it to those corrections, because I think there are other things that are objectionable.

Senator Wagner:—No matter what we did, you would not favor this legislation, isn't that the fact?

Dr. Sensenich:—No, that is not true.

Senator Wagner:—All right, then.

Dr. Sensenich:—But the type of legislation need not necessarily follow this type. I have been trying to tell you what I had in mind.

Senator Wagner:—What do you mean by the type? Your criticism has been as to details so far.

Dr. Sensenich:—They are quite important details.

Senator Wagner:—All right. You quarrel about the formula to determine need.

Dr. Sensenich:—That is right; yes, sir.

Senator Wagner:—Have you got a better formula to suggest?

Dr. Sensenich:—We have just developed that, I think.

Senator Wagner:—You have talked about it. You said you wanted to use the word "hospital" without any further specification.

Dr. Sensenich:—Prior to that I suggested that an agency be set up and determine the need the same as any other help to give to a local community.

Senator Wagner:—Before that I thought you said there was too much help.

Dr. Sensenich:—No, I beg your pardon.

Senator Wagner:—Do you think that there should be a larger setup than here provided to determine the need?

Dr. Sensenich:—No, sir, much simpler.

Senator Wagner:—How much simpler would you say?

Dr. Sensenich:—I would say a central agency, as I have already stated, a central agency to which requests should be made if need can be demonstrated.

Senator Wagner:—Now, do you mind following that up a little? Now, what is the agency; how would you set it up? We have got the Surgeon General—now, what would you set up?

Dr. Sensenich:—You also have other agencies.

Senator Wagner:—I am speaking about this particular service.

Dr. Sensenich:—I have no objection to the Surgeon General, but with that I think that he should have advice from others, and I mean not only advice but more than participating in a judgment of those who have medical experience especially in the hospitals.

Senator Wagner:—All right. Then you would include with him a committee of doctors?

Dr. Sensenich:—Some appointments, certainly. I might say that I am not digressing here as to the suggestion—

Senator Wagner (interposing):—I want to meet your suggestion if it can be met.

Dr. Sensenich:—The suggestion of the American Medical Association of some existing agency or some one to be created.

Senator Wagner:—Now we are getting down to what you want and, as I understand it, it is some one appointed by the American Medical Association?

Dr. Sensenich:—No. sir; not necessarily.

Senator Wagner:—I would not even object to your recommending it, although I do not think that you should have the final say. Now, what further?

Dr. Sensenich:—I could not go into detail.

Senator Wagner:—You are criticizing this legislation.

Dr. Sensenich:—I have already made the suggestion, but I cannot tell you just how many changes there should be in this few moments notice. I am quite sure that considerable time was spent preparing this bill.

Senator Wagner:—Now, we have the Surgeon General plus some professional men, doctors as a part of a board to determine the question of need. Now, we have that. What next would you propose?

Dr. Sensenich:—Well, sir, I cannot give you anything more than I have in general. You cannot expect me to stand here and tell you how the bill should be drawn.

Senator Wagner:—But I want to get your idea. You say this is not workable or it is not sensible; therefore you must have something in mind that is sensible or otherwise you would not be in a position to criticize.

Dr. Sensenich:—I have already made that suggestion. I will make it again—some agency—

Senator Wagner (interposing):—All right, we will take that board. How would you propose, as the other senators said that whatever rule we have must be applicable to all of the states, that is, it must be a rule which applies universally—then you would say that you would have a test as to whether the hospitals are needed according to some test of need; is that right?

Dr. Sensenich:—Investigation of the local situation in which local authorities participate.

Senator Wagner:—That is provided here.

Dr. Sensenich:—It is not required.

Senator Wagner:—What is that.

Dr. Sensenich:—It is not required.

Senator Wagner:—You would require an investigation of the situation?

Dr. Sensenich:—In which local people be given an opportunity to be heard, because they are the people who have to support it.

Senator Wagner:—Then we have that. Would that satisfy you then?

Dr. Sensenich:—And then that it be established on a need basis.

Senator Wagner:—We have that on a need basis.

Dr. Sensenich:—And define the hospital as it is defined—

Senator Wagner (interposing):—It ought not to be given unless it is needed?

Dr. Sensenich:—That is right.

Senator Wagner:—Would that satisfy you then? Would you favor it then?

Dr. Sensenich:—I would have no opposition to this bill if—

Dr. Cary (interposing):—Doctor, let me say this—

Senator Ellender (interposing):—Dr. Sensenich, forget that you are a member of the American Medical Association.

Dr. Sensenich:—I am not taking dictation.

Senator Ellender:—Maybe Dr. Cary does not like you to go so far, but forget that you are a member of the American Medical Association, you are just a plain doctor from Indiana.

Dr. Sensenich:—That is what I am, sir. With that in mind, let me restate my position which I have stated, and I think it is understood by all of you, and that is that an agency be created and the thing be established on the basis of need, and that the local community participate in determining the need and determining the remedy to be applied. Now then, I cannot tell you of the mechanism how that bill should be drawn up, but that is the formula.

Senator Wagner:—If that were provided that way, you would be for it?

Dr. Sensenich:—Pardon me?

Senator Wagner:—Would you favor the legislation?

Dr. Sensenich:—I would favor that legislation, but you formerly asked me whether I favored this bill.

Senator Wagner:—All right: that is very fair.

Senator Murray:—Doctor, we thank you for your statement; you have been very helpful. You did a very fine job and we appreciate your candor and your assistance.

Dr. Cary:—May I ask how much further time we have?

Senator Murray:—We will keep right on until we get tired. It is very interesting.

Dr. Cary:—Mr. Chairman, I wish to state at his moment that I think we have just three more witnesses, and it might be possible that we get through this afternoon.

Senator Murray:—That will be fine.

(To be continued)

MEDICAL LEGISLATION

MEDICAL BILLS IN CONGRESS

Changes in Status.—S. J. Res. 138 has passed the Senate and the House, providing that reorganization plans numbered I and II shall take effect on July 1, 1939. H. R. 6076 has passed the House, providing for the registry of surgeons as staff officers on vessels of the United States.

Bills Introduced.—S. 2256, introduced by Senator Murray, Montana, proposes to promote the general welfare by enabling the several states to make more adequate provision for compensation for the disability or death of workers from silicosis or other dust diseases. The bill proposes for each fiscal year a federal appropriation sufficient to carry out the purposes of the act, such sum to be allotted to the states which have submitted and had approved by the Secretary of Labor state compensation plans and prevention plans. The bill defines the term "compensation plan" to mean a plan to provide protection to workers and their dependents from economic losses caused by disability or death resulting from any dust disease or other disease when accompanied by or aggravated by any dust disease. The term "prevention plan" is defined to mean a plan to promote the prevention and control of industrial health hazards causing dust diseases. S. 2487, introduced by Senator Downey, California, proposes to provide hospitalization and domiciliary care to retired enlisted men of the Army, Navy, Marine Corps and Coast Guard who are war veterans, on parity with other war veterans. H. R. 6113, introduced by Representative Costello, California, provides for pensions, compensation, retirement pay and hospital benefits for certain reserve officers of the army. H. R. 6393 and H. R. 6554, introduced by Representative Angell, Oregon, propose to authorize a federal appropriation of $11,580,000 for each fiscal year to enable the states to establish, extend and improve services for educating physically handicapped children, defined by the latter bill to include children who are crippled, blind, partially seeing, deaf, hard of hearing, defective in speech, cardiopathic, tuberculous or otherwise physically handicapped, and who for their education require an expenditure of money in excess of the cost of educating physically normal children. H. R. 6394, introduced by Representative Angell, Oregon, proposes to extend the benefits of the Social Security Act to include individuals who are physically disabled. H. R. 6497, introduced by Representative Doughton, North Carolina, proposes to amend the Social Security Act in numerous respects. Among other changes, the bill proposes to exclude from the provisions of the Social Security Act the service performed as a student nurse in the employ of a hospital or a nurses' training school by an individual who is enrolled and is regularly attending classes in a nurses' training school chartered or approved pursuant to state law and service performed as an intern in the employ of a hospital by an individual who has completed a four years course in a medical school chartered or approved pursuant to state law. H. R. 6536, introduced by Representative Norton, New Jersey, proposes to amend the act to establish a Civilian Conservation Corps so as to provide that an enrollee in the corps, or member or former member of the military establishment, who shall furnish blood from his or her veins for transfusion to the veins of an enrollee or discharged enrollee of the corps undergoing treatment in a government or civilian hospital authorized to treat such patient, shall be entitled to be paid therefor a reasonable sum not to exceed $50 for each of such transfusions undergone. H. R. 6545, introduced by Representative Whelchel, Georgia, proposes to authorize the Postmaster General to issue a special postage stamp commemorating the services of Dr. Crawford W. Long "for introducing the use of ether for anesthetical purposes." H. R. 6555, introduced by Representative Doughton, North Carolina, proposes to amend the federal law relating to the advance of funds in connection with the enforcement of acts relating to narcotic drugs, so as to permit such advances in connection with the enforcement of the Marihuana Tax Act

of 1937 and to permit advances of funds in connection with the enforcement of the customs laws. H. R. 6556, introduced by Representative Doughton, North Carolina, proposes to provide for the seizure and forfeiture of vessels, vehicles and aircraft used to transport narcotic drugs, firearms and counterfeit coins, obligations, securities and paraphernalia. H. R. 6558, introduced by Representative Geyer, California, proposes to authorize the Secretary of the Navy to acquire certain real property in the city of Los Angeles and to construct in Los Angeles a marine hospital. H. R. 6586, introduced by Representative Schwert, New York, provides for the necessary medical treatment for the service-connected disabilities of veterans who reside outside the continental limits of the United States or its territories or possessions.

District of Columbia

Bill Introduced.—H. R. 6509, introduced by Representative Vreeland, New Jersey, proposes to provide for insanity proceedings in the District of Columbia.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

State Medical Meeting and Election.—Dr. Harry H. Wilson, Los Angeles, was chosen president-elect of the California Medical Association at its sixty-eighth annual session in Del Monte May 1-4 and Dr. Charles A. Dukes, Oakland, was installed as president. The next annual session will be held in Coronado. Out of state speakers included:

Dr. Chester S. Keefer, Boston, Sulfanilamide and Sulfapyridine in the Treatment of Various Infections.
Dr. Stuart W. Harrington, Rochester, Minn., Surgical Treatment of Carcinoma of the Breast.
Dr. Goodrich C. Schaufiler, Portland, Ore., Pediatric Gynecology.
Dr. Ursus V. Portmann, Cleveland, Some Indications for the Use of Roentgen-Ray Treatment.
Dr. Nathaniel G. Alcock, Iowa City, who discussed a paper entitled "Is Cystoscopy Necessary in the Larger Prostatic Hypertrophies?" by Dr. Bean M. Palmer, Oakland.

Included in the program were symposiums on alcoholism, sulfanilamide, poliomyelitis, diseases of the gastrointestinal tract, carcinoma of the breast and headaches. It was decided at the recent session to assess each member of the association $10 to raise a fund to be used solely for public relations activities.

DELAWARE

Research Conference.—The first session of the ninth annual research conference of Johns Hopkins University at the Henlopen Hotel, Rehoboth, June 5-9, was devoted to biochemistry under the chairmanship of Leslie Hellerman, Ph.D., associate in physiological chemistry, as chairman. During the second week, June 12-16, lectures on organic molecules and organic reactions will be presented with Alsoph H. Corwin, Ph.D., as chairman. Further information may be obtained from Paul H. Emmett, Ph.D., Johns Hopkins University, Baltimore.

DISTRICT OF COLUMBIA

Society News.—Dr. Harry F. Dowling discussed "The Treatment of Pneumonia with Sulfapyridine" before the Washington Medical and Surgical Society April 24.——At a meeting of the George Martin Kober Medical Society April 17, Dr. Lyle M. Mason discussed "A Résumé of Sulfanilamide Therapy in Urology." A neuropsychiatric case report was presented by Dr. Joseph L. Gilbert.

The Gibson Award.—Dr. Howard F. Kane, professor of obstetrics and gynecology, George Washington University School of Medicine, Washington, received the Frank E. Gibson annual award of certificate and purse for "meritorious contributions to medical science" at the annual banquet of the Washington Medical and Surgical Society May 6. Dr. Beveridge Miller was chosen president of the society at this meeting; Dr. Henry J. Russell McNitt, vice president; Dr. Thomas C. Thompson, secretary, and Dr. Frank E. Gibson, treasurer.

Dr. Bloedorn Named Dean at George Washington.—Dr. Walter A. Bloedorn, professor of medicine, George Washington University School of Medicine, Washington, has been appointed dean of the school. The appointment fills the vacancy that occurred when Dr. Earl B. McKinley was lost on the Hawaii Clipper in July 1938. Born in 1886 at Platte Center, Neb., Dr. Bloedorn graduated at Creighton University School of Medicine, Omaha, in 1909. He later studied at George Washington University and the New York Post-Graduate Medical School and Hospital. He is also chief of staff at Gallinger Municipal Hospital, Washington, and a commander, medical corps, U. S. Navy, retired.

FLORIDA

Seventh Annual Graduate Short Course.—The seventh annual graduate short course for doctors of medicine under the auspices of the Florida Medical Association and the state board of health will be held in Daytona Beach June 19-24. Lecturers will include:

Dr. Wilburt C. Davison, dean and professor of pediatrics, Duke University School of Medicine, Durham, N. C.
Dr. Beverley R. Tucker, emeritus professor of neuropsychiatry, Medical College of Virginia, Richmond.
Dr. Maurice C. Pincoffs, professor of medicine, University of Maryland School of Medicine, Baltimore.
Dr. William T. Pride, professor of obstetrics, University of Tennessee School of Medicine, Memphis.
Dr. Raymond W. McNealy, associate professor of surgery, Northwestern University Medical School, Chicago.
Dr. Robert J. Crossen, assistant professor of clinical obstetrics and gynecology, Washington University School of Medicine, St. Louis.

Wednesday evening June 21 there will be an open meeting of the Duval County Medical Society at Ponte Vedra Beach, to which all physicians attending the course are invited.

ILLINOIS

Society News.—Drs. Waltman Walters and Edwin J. Kepler, both of Rochester, Minn., discussed "Adrenal Cortical Neoplasms" before the Peoria City Medical Society May 19.——At a meeting of the Hancock County Medical Society in Carthage May 8 Dr. Leon Unger, Chicago, spoke on hay fever.——Dr. George L. Apfelbach, Chicago, addressed the Grundy County Medical Society at Starved Rock, April 25, on "Diagnosis of Lower Back Pains."——Dr. Vivien P. Siegel, East St. Louis, discussed "Infections of the Hand" before the Madison County Medical Society in Wood River May 5.

Chicago

Dr. Bundesen Returns to Department of Health.—Dr. Herman N. Bundesen, who has been on a leave of absence since November 1938, has returned to his activities as health commissioner and president of the Board of Health of Chicago. Dr. Robert A. Black, who had been acting president of the board during Dr. Bundesen's absence, had asked to be relieved so that he could devote his full time to his private practice, it was reported.

Branch Meetings.—Dr. Guy S. Van Alstyne discussed "The Management of Biliary Tract Surgery" before the Southern Cook County Branch of the Chicago Medical Society May 16.——At a meeting of the Calumet Branch May 19 Dr. William D. McNally spoke on "Practical Aspects of Toxicology in General Practice."——Mr. Henry P. Chandler, president, Chicago Bar Association, addressed the Northwest Branch May 19 on "Cooperation of the Legal and Medical Professions."——The South Chicago Branch was addressed May 23 by Dr. Edward L. Cornell on "The Reckless Interference with the Normal Process of Labor."——Dr. Michael L. Mason discussed "Management of Open Wounds" before the Irving Park Branch May 23.

INDIANA

Distribution of Pneumonia Serum.—The state board of health has approved a plan for distributing pneumonia serum advanced by the pneumonia committee of the state medical association. Distribution points will be established in each of the association's districts, and from twelve to fifteen such centers will be operated. Hospitals or laboratories centrally located will be used. According to the state medical journal, the 1939 session of the general assembly appropriated $75,000 a year to purchase pneumonia serum and certain other serums and antitoxins. A decision by Omer S. Jackson, attorney general, holds that the board cannot use any of this fund for the purchase of sulfapyridine.

KANSAS

Dinner for the Secretary.—Clarence Munns, executive secretary, Kansas Medical Society, Topeka, was guest of honor April 21 at a meeting of the Pratt County Medical Society. Guest speakers at the meeting, which was attended by 125 physicians, were Drs. John L. Lattimore and Forrest L. Loveland, both of Topeka. Mr. Munns was presented with a chest of sterling silver consisting of a complete service for eight The gift was purchased through contributions obtained by the Pratt County Medical Society from the physicians of western Kansas. Dr. Herbert Atkins, Pratt, was toastmaster and Dr. Noble E. Melencamp, Dodge City, made the presentation.

MICHIGAN

Personal.—Dr. Helen E. P. Lanting is in charge of the newly opened clinical laboratory in Escanaba.——Dr. Thomas K. Gruber was presented with a Browning Over-and-Under Shotgun by the resident medical staff of Eloise Hospital May 1 in recognition of his having completed ten years as superintendent of the hospital.——Dr. William C. Ellet was elected mayor of Benton Harbor recently.

Society News.—The Wayne County Medical Society Glee Club gave its fifth annual concert April 24.——Dr. Ralph G. Cock was chosen president-elect of the Kalamazoo Academy of Medicine, in accordance with a recently adopted policy of the academy. Dr. Ralph B. Fast is president.——Dr. Harry J. Isaacs, Chicago, addressed the Calhoun County Medical Society, Battle Creek, May 2 on diagnosis and treatment of heart failure. ——Dr. William D. Robinson, Ann Arbor, addressed the Washtenaw County Medical Society, Ann Arbor, May 9 on "Indications for Therapeutic Use of Vitamin B."

MISSISSIPPI

State Medical Meeting and Election.—Dr. William H. Anderson, Booneville, was chosen president-elect of the Mississippi State Medical Association at its annual meeting in Gulfport in May and Dr. James P. Wall, Jackson, was inducted into the presidency. The next annual session will be held in Jackson May 14-16. Out of state speakers at the recent meeting included:

Dr. Roderick Heffron, New York, The Public Health Aspects of Pneumonia.
Dr. Paul Padget, Baltimore, The Public Health Aspects of Syphilis Control.
Dr. Oscar W. Bethea, New Orleans, Treatment of Pneumonia.
Dr. Grady E. Clay, Atlanta, Treatment of Convergence Squint.
Dr. Carl E. Granberry, New Orleans, The Tracheotomy—Its Dangers and Complications.
Dr. Edward William Alton Ochsner, New Orleans, The Surgical Significance of Amebiasis.
Dr. Cobb Pilcher, Nashville, Tenn., The Late Complications of Head Injuries and Their Treatment.
Dr. William Milton Adams, Memphis, Tenn., Modern Concepts in the Treatment of Facial Injuries.
Dr. Arthur Carlton Ernstene, Cleveland, Diagnosis and Treatment of Coronary Artery Disease.
Dr. Earl H. Floyd, Atlanta, Ga., The Relation Between Urology and Other Branches of Medicine.

Dr. Oren Moore, Charlotte, N. C., delivered the Ewing Fox Howard oration on "Modern Trend of Obstetrics." The Mississippi State Hospital Association held its tenth annual meeting just prior to the session of the state medical association.

MONTANA

State Medical Meeting at Butte.—The sixty-first annual scientific session of the Medical Association of Montana will be held at the Finlen Hotel, Butte, June 28-30, under the presidency of Dr. James C. MacGregor, Great Falls, and with the Silver Bow County Medical Association acting as host. At the annual banquet Thursday Dr. Rock Sleyster, Wauwatosa, Wis., President, American Medical Association, will give the principal address on "Medical Problems of the Day." Dr. Chris E. Emery, Butte, will be toastmaster. Presenting the scientific program will be:

Dr. Ernest Sachs, St. Louis: Head Injuries; The Present Status of Surgery of Brain Tumors.
Dr. Dalton Keats Rose, St. Louis: Bladder Obstruction, Male and Female; Neurogenic Bladder, Particularly in the Application of Handling Those Seen in Association with Ever Increasing Automobile Accidents.
Dr. James Barrett Brown, St. Louis, Management of Compound Injuries of the Face and Jaws; The Repair of Surface Defects Due to Burns and Other Causes.
Dr. Charles Darrell O'Keefe, St. Louis, Cesarean Section—Its Indication, Technic and Results; Endometriosis.
Dr. Carl V. Moore, St. Louis: Splenectomy in the Treatment of Blood Diseases; Recent Advances in the Understanding and Treatment of Deficiency Diseases.
Mr. A. G. Stacil, business manager, Nicollet Clinic, Minneapolis, Group Hospitalization.

NEW HAMPSHIRE

Society News.—The Carroll County Medical Society held its quarterly meeting in Center Ossipee May 7 with Dr. Roland D. Clapp, Lewiston, Me., as a guest speaker on recent progress in roentgenology. Dr. Clarence O. Coburn, Manchester, president of the New Hampshire Medical Society, discussed the work of the society. Mrs. Harry A. Cheney, Campton, president of the woman's auxiliary to the state medical society, addressed the women present.

NEW YORK

Symposium on Silicosis.—The fourth annual silicosis symposium at the Saranac Laboratory, Saranac, will be offered June 19-23. Lecturers will include: Philip Drinker, Ch.E., Boston; Drs. Leroy U. Gardner, director of the laboratory; William S. McCann, Rochester; Eugene P. Pendergrass, Philadelphia; Adolph G. Kammer, Chicago; Royd R. Sayers, U. S. Public Health Service, Washington, D. C.; Anthony J. Lanza, New York; Clarence D. Selby, Detroit, and Oscar A. Sander, Milwaukee, and Mr. Voyta Wrabetz, chairman, Wisconsin State Industrial Commission, Madison. Registration will be limited to 100 and the fee is $25.

New York City

Personal.—Dr. Sigismund S. Goldwater, commissioner of hospitals, received the third annual award of the City Club of New York April 28. This award is made annually to a nonelective public servant who has in the estimation of the trustees rendered outstanding public service to the city.

Dr. Alfred E. Cohn Honored.—Dr. Alfred E. Cohn of the Rockefeller Institute for Medical Research was guest of honor at a dinner at the Waldorf-Astoria April 29, which about 225 persons attended. Dr. Cohn was presented with a volume of more than 300 letters, written by friends in America and abroad in honor of his sixtieth birthday. Dr. Cohn graduated from the College of Physicians and Surgeons of Columbia University in 1904, has been on the staff of the Rockefeller Institute since 1911 and a member since 1920. His special field is research on cardiovascular disease.

Society News.—Dr. Richard Kovacs addressed the Medical Society of the County of Queens May 23 on "Physical Therapy and the General Practitioner" and John T. Keudell, acting police captain in the Grand Central Parkway Precinct, "Traffic Regulations and the Doctor."——A symposium on diagnostic aids in cardiovascular disease was presented at a meeting of the Medical Society of the County of New York May 22 by Drs. Hugo Roesler, Philadelphia, Charles E. Kossmann, George P. Robb and Israel Steinberg.——Dr. Ralph H. Boots addressed the Bronx County Medical Society, May 25, on "Chronic Arthritis."——Dr. Morris Fishbein, Chicago, Editor of THE JOURNAL, addressed the Medical Society of the County of Kings May 23 on "Current Aspects of Medical Legislation" and the Hon. Robert F. Wagner Jr., member of the state assembly, on "The National Health Program."——Dr. David Marine addressed the New York Endocrinological Society May 24 on "The Problem of Exophthalmos."——A symposium on cancer of the breast was presented by Drs. David E. Ehrlich, Samuel G. Schenck and Frank E. Adair before the Long Island Radiological Society April 27.

NORTH DAKOTA

State Medical Election.—Dr. Cyril J. Glaspel, Grafton, was chosen president-elect of the North Dakota State Medical Society at its annual meeting in Fargo May 9, and Dr. Harry A. Brandes, Bismarck, was installed as president. Drs. Frederick W. Fergusson, Kulm, and Alfred R. Sorenson, Minot, were elected vice presidents and Dr. Albert W. Skelsey, Fargo, was reelected secretary. The 1940 meeting will be held in Minot.

OHIO

State Medical Election.—Dr. William M. Skipp, Youngstown, was chosen president-elect of the Ohio State Medical Association and Dr. Parke G. Smith, Cincinnati, was installed as president at the annual session in Toledo May 4. The 1940 session will be in Cincinnati.

Society News.—Reuben L. Kahn, Sc.D., Ann Arbor, Mich., addressed the Montgomery County Medical Society, Dayton, May 5, on "Paradoxic Serum Reactions in Syphilis."——Drs. Leo P. Dolan and Arthur A. Brindley, Toledo, addressed the Auglaize County Medical Society, St. Marys, April 13, on "Urological Problems as Best Handled by the General Practi-

tioner" and "Different Types of Anesthesias" respectively.——Dr. William Gordon Hartnett, Fostoria, discussed "Diagnosis of the Cardiac Arrhythmias by Aid of the Electrocardiograph" before the Seneca County Medical Society, Fostoria, April 13.——Dr. William J. Engel, Cleveland, addressed the Erie County Medical Society, Sandusky, in April on "Treatment of Acute Urinary Retention."

OREGON

Society News.—At a joint meeting of the Central Willamette Medical Society with the Lane County Medical Society in Eugene April 6 Dr. DeWitt C. Burkes, Portland, spoke on "Diagnostic Methods in Neurology."——Dr. Joseph Levitin, San Francisco, addressed the Polk-Yamhill-Marion Medical Society April 11 in Salem on "Ileus, Intussusception and Intestinal Obstruction."

Lectures in Obstetrics.—The committee on maternal welfare of the Oregon State Medical Society and the state board of health sponsored a series of lectures in nine cities during May. Drs. Daniel G. Morton, assistant professor of obstetrics and gynecology, University of California Medical School, and John Mott Rector, visiting pediatrician, Children's and St. Mary's hospitals, San Francisco, were the lecturers. Meetings were held in Astoria, Albany, Eugene, Salem, The Dalles, Bend, Medford, Marshfield and Hood River.

PENNSYLVANIA

Society News.—Drs. Priscilla White and Howard F. Root, Boston, were guests at a clinic meeting of the Lycoming County Medical Society, Williamsport, May 12; Dr. White discussed juvenile diabetes and Dr. Root, surgical complications of diabetes. The society's third postgraduate seminar was held May 26 with Dr. Seymour D. Ludlum, Philadelphia, as the instructor on "Diseases of Constitutional Inferiorities."——Dr. Stanley P. Reimann, Philadelphia, addressed the Lebanon County Medical Society, Lebanon, May 9 on "Nonspecific Treatment of the Cancer Patient."

Philadelphia

Personal.—Drs. John Cajetan Flynn and William P. Grady will receive the honorary degree of doctor of laws at the annual commencement of St. Joseph's College, Philadelphia, June 13. Dr. Flynn is chief visiting physician at St. Joseph's Hospital and Dr. Grady senior laryngologist at St. Mary's Hospital.

Courses for Medical Alumni.—Temple University School of Medicine announces postgraduate courses for medical alumni to be given by the faculty June 13-14. There will be a registration fee of $2. Application for registration should be mailed to Dr. William N. Parkinson, dean, Broad and Ontario streets.

Society News.—The Philadelphia County Medical Society held a "doctors' and nurses' night" May 10. The speakers were Drs. Charles H. Henninger, Pittsburgh, president-elect, Medical Society of the State of Pennsylvania on "The Patient, Nurse and Doctor" and David W. Thomas, Lock Haven, president of the state society, on "Cooperation"; Miss Mary A. Rothrock, president, Pennsylvania State Nurses' Association, "Nursing in Perspective," and Miss Helen Leader, directress of nurses, Presbyterian Hospital, "Eight Hour Duty."

Pittsburgh

The Mellon Lecture.—The twenty-second Mellon Lecture, sponsored by the Society for Biological Research of the University of Pittsburgh School of Medicine, was presented May 11 by Charles Judson Herrick, Ph.D., professor emeritus of neurology, University of Chicago. Dr. Herrick's subject was "A Neurologist Makes Up His Mind."

SOUTH CAROLINA

National Foundation Sends Aid in Poliomyelitis Epidemic.—The National Foundation for Infantile Paralysis has sent to Dr. James A. Hayne, state health officer, contributions of $7,650 to aid in financing a program of treatment for victims of an outbreak of poliomyelitis in the state. Dr. Hayne has asked the federal government for an equal amount, the whole fund to be used to provide orthopedic nursing consultants, physiotherapy technicians, examinations by orthopedic surgeons, diagnoses by pediatricians, hospitalization of about 100 children for thirty days, convalescent and foster home care of about twenty-two children and orthopedic appliances. The foundation also sent to every physician in South Carolina a copy of a bulletin entitled "Care During the Recovery Period in Paralytic Poliomyelitis." It is reported that about 140 cases had developed up to June 2, of which ninety are in Charleston. The U. S. Public Health Service reports that no federal quarantine has been established.

TEXAS

District Meeting.—The annual meeting of the Panhandle District Medical Society was held in Amarillo April 11-12. Among the speakers were:

Dr. George H. Garrison, Oklahoma City, Convulsions in Children.
Dr. D. Columbus Hyder, Memphis, Tenn., Some Obstetric Tragedies.
Dr. Harry H. McClellan, San Antonio, Is Mental Disease an Inherited Defect or an Acquired Delirium?
Dr. Will S. Horn, Fort Worth, Chronic Insomnia.
Dr. Walton G. Stephens, Borger, Factors Governing Healing of Abdominal Wounds.

Dr. Ernst W. Bertner, Houston, president of the Texas State Medical Association, addressed a luncheon meeting on state medicine.

PHILIPPINE ISLANDS

Personal.—Capt. Joseph J. A. McMullin, Medical Corps, U. S. Navy, medical officer in command of the U. S. Naval Hospital, Canacao, has been appointed assistant adjunct professor of surgery at the College of Medicine in the University of the Philippines, Manila.

GENERAL

Society News.—The fourteenth annual meeting of the American Society of X-Ray Technicians will be held at the Hotel McAlpin, New York, June 27-30.——Dr. Forrest L. Loveland, Mills Building, Topeka, Kan., has been chosen secretary of the Northwest Regional Conference; Dr. Louis Fernald Foster, Bay City, Mich., is the president.

Insurance Medical Directors Meet.—The twenty-ninth annual meeting of the Medical Section of the American Life Convention will be held at The Homestead, Hot Springs, Va., June 27-29. The guest speakers will be Drs. Harold M. Marvin, New Haven, Conn., who will discuss "Some Aspects of Cardiovascular Disease," and Ray F. Farquharson, Toronto, Ont., "Recent Advances in Clinical Medicine and Practical Application to Insurance Medicine." Dr. Albert E. Johann, Des Moines, Iowa, is chairman of the medical section.

International Neurologic Congress.—In view of the doubt expressed by some Americans as to the advisability of holding the Third International Neurological Congress in Copenhagen August 21-25, the American committee has communicated with the Danish committee asking for an expression of opinion. The Danish committee has replied that they believe it is advisable to continue with the plans for the congress, that if present conditions continue there will be no question about postponement and that it will be held in Copenhagen as already determined.

Special Society Elections.—Dr. George H. Stevenson, London, Ont., was chosen president-elect of the American Psychiatric Association at its recent annual meeting in Chicago and Dr. William C. Sandy, Harrisburg, Pa., was installed as president. Dr. Arthur H. Ruggles, Providence, R. I., is the secretary-treasurer.——Dr. Gerald B. Webb, Colorado Springs, was chosen president of the Association of American Physicians at its annual meeting in Atlantic City May 3. Other officers include Drs. Hugh J. Morgan, Nashville, secretary, and William S. McCann, Rochester, N. Y., treasurer, reelected.

Medical Library Association.—The forty-first annual meeting of the Medical Library Association will be held in Newark, N. J., June 27-29, at the Academy of Medicine of Northern New Jersey. Among the speakers announced are:

Miss Linda H. Morley, Columbia University Library School, Special Library Policies and Methods.
Dr. Karl M. Scott, Atlantic City, N. J., and Lieut.-Col. Edgar E. Hume, U. S. Army, The Literature of Syphilis.
Miss Margaret Bates, University of Illinois College of Medicine, Chicago, Medical Stamps.
Dr. Arthur H. Sanford, Rochester, Minn., The Supporting Member.
Mary A. Bennett, Ph.D., and Miss Dorothy H. Litchfield, Columbia University, New York, Problems of Microphotography.

At the annual banquet Dr. Charles H. Young, Montclair, N. J., will discuss "The Airplane in Medicine" and Capt. Arthur Caperton, American Airlines, "Spectacular Flights."

Symposium on the Cell and Protoplasm.—Following the meeting of the Pacific Division of the American Association for the Advancement of Science at Stanford University, a symposium on the cell and protoplasm will be presented by biologists and physicists from June 30 to July 5. The speakers will include: Dr. Albert Szent-Györgi, University of Szeged,

Hungary, on "Vitamins"; Dr. Ross G. Harrison, Yale University, New Haven, Conn., "Cellular Differentiation and Internal Environment"; Wendell M. Stanley, Ph.D., Rockefeller Institute for Medical Research, Princeton, N. J., "Viruses" and Edwin G. Conklin, Ph.D., Princeton University, Princeton, N. J., "Cell and Protoplasm Concepts: Historical Account."

Proctologic Society Meeting.—The fortieth annual meeting of the American Proctologic Society will be held at the Hotel St. George, Brooklyn, June 25-27. Among the speakers will be:

Dr. Albert F. R. Andresen, Brooklyn, Allergic Manifestations in the Colon.
Dr. John Scudder, New York, Blood Studies in Shock and Guides to Therapy.
Drs. Jerome M. Lynch and George Johnson Hamilton, New York, Lymphosarcoma of the Rectum.
Dr. Walter A. Fansler, Minneapolis, Preoperative Preparation and Postoperative Care in Abdominoperineal Resections.
Dr. Granville S. Hanes, Louisville, Ky., Proctology Not in Books.
Dr. Garnet W. Ault, Washington, D. C., Rectal Perforations by Enema Tips.

In addition, there will be a program of case reports and a clinic at Brooklyn Hospital. A plan to hold a joint meeting July 10-11 with proctologists in London, England, has been postponed until a more favorable year.

Prize for Research on Human Genital Organs.—Announcement is made of the Francis Amory Septennial Prize of more than $10,000 for outstanding work with reference to the alleviation or cure of diseases affecting the human genital organs. Provided there is work of a quality to warrant it, the first award will be made in 1940. The total amount of the award will exceed $10,000 and may be given in one or more awards. The fund was established by the will of the late Francis Amory, Beverly, Mass., with the American Academy of Arts and Sciences as the judge and distributor. It rests solely within the discretion of the academy whether an award shall be made at the end of any given seven year period and also whether on any occasion the prize shall be awarded to more than a single individual. While there will be no formal nominations, and no formal essays or treatises will be required, the committee invites suggestions which should be made to the Amory Fund Committee, care of the American Academy of Arts and Sciences, 28 Newbury Street, Boston.

Activities in Protection of Eyesight.—The National Society for the Prevention of Blindness continued its activities in many fields during the past year, the annual report shows. It has distributed large amounts of educational material and participated in many campaigns to promote the protection of eyesight, such as the syphilis control campaign. Sight-saving classes for school children, inaugurated in 1913, have grown to 589 in 1938, an increase of thirty-one over 1937. The society cooperates with a number of colleges and universities each summer in offering special courses to train teachers for these courses. A transcribed radio program for presentation on the Fourth of July to warn against eye tragedies during the holiday was an outstanding activity of the year. The society is also working with a committee of the American Student Health Association in studying the health of college students. Revision of the society's handbook for safety engineers and others concerned in the prevention of blindness in industry was undertaken during the year. An institute on eye health offered training to welfare workers in the sight conservation aspects of their work. The society's income for 1938 was $126,000 and its expenditures amounted to $169,000. Financial support is received from 17,000 members and donors in all parts of the country.

CANADA

Canadian Medical Association Meeting.—The seventieth annual meeting of the Canadian Medical Association will be held in Montreal June 19-23, under the presidency of Dr. Kenneth A. MacKenzie, Halifax, N. S. Dr. Allen O. Whipple, New York, will deliver the Lister Oration at a general session Friday June 23 on "A Consideration of Recent Advances in Surgery in the Light of Lord Lister's Studies." Other speakers at the general sessions include:

Dr. Jonathan C. Meakins, Montreal, A Review of the Present Status of Hypertension.
Dr. Arthur J. Bedell, Albany, N. Y., Retinal Changes in Arterial Hypertension.
Dr. Edward P. Cathcart, Glasgow, Scotland, Nutrition.
Dr. Norman F. Miller, Ann Arbor, Mich., Treatment of Dysmenorrhea.
Prof. Arthur B. Appleton, London, England, Physical Exercises.

Professor Cathcart will give a public address on "Food and Nutrition" Monday evening June 19.

Public Health Association Meeting.—The twenty-eighth annual meeting of the Canadian Public Health Association will be held in Toronto June 12-14 at the Royal York Hotel. Among the speakers will be Dr. Haven Emerson, New York, on current practice in communicable disease control; Sir Arthur Salusbury MacNalty, chief medical officer of the ministry of health of Great Britain, on the British national health insurance scheme and Prof. Edward P. Cathcart of the University of Glasgow, Scotland, on nutrition. Dr. Robert E. Wodehouse, Ottawa, deputy minister of pensions and national health, is president of the association.

FOREIGN

Protection of Populations in War.—A congress of the medical and legal professions will be held in Liege, Belgium, June 24-28, to consider problems involved in the protection of the civil population in time of war. According to the announcement, all physicians, civil and military, doctors of law and officers of the land, sea and air forces, as well as technicians interested in these problems are invited to attend. The secretary general of the congress is Dr. Georges Decharneux, 13 rue des Maraichers, Liege, Belgium.

Ministry of Health Appoints Consultants.—The British Minister of Health has appointed the following consultant advisers on the organization of hospitals in England and Wales in war time, according to *Science:* Dr. Gordon M. Holmes, neurology; Dr. Bernard Hart, psychiatry; Dr. Gwynee E. O. Williams, orthopedic surgery; Sir Cuthbert S. Wallace, general surgery; Sir Harold D. Gillies, facial and jaw injuries; Dr. Arthur Tudor Edwards, chest wounds; Dr. Hugh Cairns, head injuries; Dr. Francis R. Fraser, general medicine; Dr. William M. Mollison, ear, nose and throat; Dr. Charles B. Goulden, ophthalmology, and Dr. Alfred E. Barclay, radiology. The presidents of the Royal Colleges of Physicians and Surgeons made the nominations for these appointments.

CORRECTION

Dr. Carrel's Retirement.—A news item in THE JOURNAL, May 20, page 2071, stated that Dr. Alexis Carrel, among others, would retire from the staff of the Rockefeller Institute for Medical Research and that "every laboratory facility will be provided to enable those who retire to continue their research work on their own responsibility if they care to do so." Dr. Carrel writes that his staff is being dispersed and his department closed and that this inevitably brings to an end all his research, including the development of the new method for the cultivation of entire organs in the Lindbergh apparatus. The original information was taken from *Science.*

Government Services

Admiral Butler Retires

Rear Admiral Charles St. J. Butler, medical corps, who retired for age April 1, was ordered detached March 31 as president of the naval retiring board and board of medical examiners and naval retiring board for officers of the medical corps and to proceed home. Capt. Benjamin H. Dorsey, medical corps, has advanced to the rank of rear admiral and been assigned to succeed to duty as president of these boards at the navy department, according to the *Military Surgeon.*

Colonel Siler to Retire

Col. Joseph F. Siler will retire from active service in the medical corps of the U. S. Army, June 30, after about thirty-nine years' service. Dr. Siler graduated at the University of Virginia Medical Department in 1898. He was chairman of the Thompson-McFadden pellagra commission, 1912-1915. He served as chief of professional service division, office of the surgeon general, 1925-1929; chief health officer, Panama Canal, 1929-1934. He entered the service as contract surgeon in 1900, and advanced through the various ranks until 1929, when he was appointed colonel. He was awarded the Distinguished Service Medal and has written extensively on pellagra, dengue fever and typhoid. He is a member of many scientific societies and served as president of the American Society of Tropical Medicine. The successor to Colonel Siler as director of the Professional Service Schools at the Army Medical Center has not been announced.

LONDON

(From Our Regular Correspondent)

May 13, 1939.

Blood Transfusion Service Established

The minute detail in which preparation is being made for dealing with civil casualties of air raids has been pointed out previously. The latest is the establishment of a national emergency blood transfusion service for London at four centers in adjacent cities. Blood immediately available for transfusion to air casualties will be stored in underground refrigerators. Existing donors will have the option of enrolling at their local hospitals or of giving blood at one of the stores. The present London service would cease, as ordinary patients would be transferred for greater safety to hospitals far outside its area. During the September crisis steps were taken to establish a large supply depot within a convenient distance of London. Preparations were so far advanced that the supply would have begun within seven days of the outbreak of hostilities. In the meantime hospitals were advised to store an adequate amount of blood for their immediate needs. Excavations are proceeding for the construction of an underground refrigerated store and properly protected surgery, laboratory and waiting rooms as well as residency for the medical and administrative staff.

The Medical Peace Campaign

Under the presidency of Prof. J. A. Ryle of Cambridge an organization of physicians called the Medical Peace Campaign has been formed. They argue that, as the medical profession is responsible to a large extent for the prevention of disease and suffering, it should take what measures it can to prevent war. The committee has therefore drawn up proposals addressed to physicians throughout the world.

Realizing the suffering caused by war and accepting its medical responsibility to prevent disease, the committee urges the governments of the world to take action to make war impossible. In particular it suggests that, to combat the present emergency, Great Britain, France and Russia should declare that they stand united to resist all further aggression by military force if necessary and that the governments of these countries should invite all other countries, irrespective of their form of government, to associate themselves with this declaration. They maintain that the only way to eliminate all possibility of future war is to establish the rule of international law, based on the principle of justice to all and backed by overwhelming military and economic strength. To this end they urge that a conference be called to discuss the practical measures which should be taken. Finally, regarding medicine as the most international and humane of the professions, they remind their colleagues in all countries of the great part which they may yet play in influencing public opinion on behalf of peace.

Virus Diseases

At a meeting of the Royal Society of Tropical Medicine and Hygiene at which viruses were discussed, Dr. K. M. Smith said that since Iwanowsky discovered the first virus in 1892 a large number of plant and animal viruses had been described. Of the former no fewer than 163 viruses and virus strains were on record. In the affected plants the symptoms were extremely varied. Almost the only point in common was their uniform distribution over most of the plant as the result of the systemic nature of the infection. This contrasted with the more localized lesions caused by other pathogenic agents. A less usual result was a general chlorosis or yellowing of the plant with various distortions. Virus-diseased plants generally did not die. Two kinds of intracellular inclusions were found —a large, rounded, vacuolated mass generally near the nucleus and crystalline plates, as in tobacco mosaic.

Virus diseases could be disseminated experimentally by inoculation and were spread naturally by contact or by air, water, soil and insects. Almost all the transmitting insects were Hemiptera which sucked sap by a piercing apparatus. Though animal viruses multiplied in the insect vector, there was no proof that this occurred in plant viruses.

Prof. S. P. Bedson said that animal viruses were transmitted in a variety of ways, but that insects played a less important part than with plant viruses. Rabies, venereal lymphogranuloma, molluscum contagiosum and warts were distributed by direct contact. The virus of influenza was transmitted by droplet spray infection and of variola and varicella by dried particles.

The great difference between the tissues of the plant and those of the insect rendered improbable multiplication of the plant virus in insects. The delimitation of the virus group was based on (1) small size and filtrability, (2) inability to multiply apart from living cells and (3) production of inclusion bodies. These criteria would include the agents causing trachoma, inclusion conjunctivitis, venereal lymphogranuloma, psittacosis and infection with Rickettsia. He would classify all these as a right wing group. In a left wing group he would classify the very small animal viruses which appeared homogeneous in composition—nucleoprotein. But it was impossible to say whether they were similar to crystallizable plant viruses. The remainder he would classify in a center group with right and left affinities. Rickettsia bridged the gap between the right wing group and the bacteria.

Vitamin E

At a conference on vitamin E, arranged by the Society of Chemical Industry, Dr. K. E. Mason of Vanderbilt University, Nashville, Tenn., said that placental transfer of the vitamin in the rat was nil and mammary transfer exceedingly limited, even when the intake was increased to 2,000 times the minimal. Dr. S. W. F. Underhill pointed out that the effects of vitamin deficiency in the rat were similar to those produced by hypophysectomy. Hypoplasia of the thyroid and degenerative changes in the anterior lobe of the pituitary had been found. Administration of vitamin E would cure the paralysis observed in suckling rats, stimulate normal growth and arrest testicular degeneration due to deficiency of the vitamin. Prolonged deficiency caused degeneration of the ovaries and uterus. Dr. T. S. Moore said that deficiency in female rats produced a brown discoloration but that in males the seminal vesicles were discolored. Prolonged deficiency produced sores in the skin and eventually emaciation and death. Miss A. M. Copping and Prof. V. Korenchevsky of the Lister Institute had found that deficiency from birth produced diminished weight of the body and of the internal organs.

A discussion on clinical applications was opened by Dr. P. Vogt-Muller of Copenhagen. Wheat germ oil gave 75 per cent of success in the treatment of barren cows and 70 per cent in barren sows. In human medicine vitamin E was successful in from 75 to 80 per cent of cases of habitual abortion. The treatment had also been effective in cases of threatened abortion, premature separation of the placenta and the toxemia of pregnancy. Dr. E. V. Shute of the University of Western Ontario said that a deficiency of vitamin E might be detected by a test of the estrogen vitamin E equilibrium of the blood. Deficiency of the vitamin must be very common in the nonpregnant. It was found in pregnant hypothyroid patients and in cases of abortion and accidental hemorrhage. The most important and earliest sign was uterine tenderness at the placental site. Wheat germ oil as a source of vitamin E should be fresh and preserved cold. Mr. D. W. Currie had treated

ninety-five cases of habitual abortion with wheat germ oil, alone or with progesterone, and had obtained 80 per cent of living births. In cases of threatened abortion he obtained an even higher percentage of full term pregnancies.

The International Standard for Chorionic Gonadotropin

At the third International Conference on the Standardization of Hormones, in Geneva last year, it was decided to establish international standards for hormones of the anterior pituitary and the analogous substances of urine and serum. The preparation of these standards, their storage and their dispensing were left to the National Institute of Medical Research of Great Britain. The institute has prepared the international standard for the gonadotropic substance of human urine (chorionic gonadotropin) from material provided by six different countries. The standard is dispensed in tablets of 10 mg. The international unit is defined as the gonadotropic activity of 0.1 mg. of the standard preparation, which is the amount required to produce cornification of the vaginal epithelium of the immature rat. Thus each tablet contains about 100 international units. Like international standards for other hormones, drugs and vitamins, the standard for chorionic gonadotropin is held by the National Institute for Medical Research on behalf of the Health Organization of the League of Nations. It is distributed to national centers established in other countries or to workers in countries where centers have not been set up.

First Aid Posts in London

The minister of health has approved schemes submitted by the metropolitan boroughs and the corporation of the city for the establishment of 131 fixed first aid posts, five cleansing stations and thirty-four mobile units for London. The estimated total required is 200. One physician is to be appointed by the local authority for each post and sixty voluntary helpers. Of these the total number required is 12,000 women, but already 17,000 have volunteered. The number of men volunteers required is 2,591, and almost this number has been enrolled. The fixed posts will be located mostly in hospitals or the basements of institutions.

PARIS

(From Our Regular Correspondent)

May 6, 1939.

Tetanus Anatoxin

Through a series of studies starting with the discovery of diphtheria anatoxin about fifteen years ago, Gaston Ramon has set up new methods for the prophylaxis and treatment of tetanus: vaccination proper, serovaccination, anatoxic serotherapy and emergency prevention through the use of solutions of antitoxin. Since 1926 the dose of anatoxin has been specified for antitetanus vaccination. Three injections are necessary. Unlike diphtheria anatoxin, tetanus anatoxin does not cause intolerance. Diversified protection can be assured, increasing the effects of each, through mixing tetanus anatoxin with antityphoid vaccine and diphtheria anatoxin.

Antitetanus vaccination has received a unanimously favorable reception in France; it has been estimated that one and a half million persons have been vaccinated. Antitetanus vaccination has been obligatory in the army for two years; more than 800,000 men have been vaccinated.

Compared with antitetanus serum, the anatoxin was found to be stronger and more lasting. On the other hand, none of the vaccinated subjects had tetanus. Serovaccination gives protection which is achieved rapidly but is of short duration, and postserum tetanus occurring as late as the third month after vaccination has been reported. Experience has proved that immunization can become lasting if serovaccination and the use of anatoxin are associated as a routine. Such association is recommended as a therapeutic measure also; it really is an efficacious toxin-anatoxin treatment.

The benefits of anatoxin vaccination have been extended to the horses and mules of the French army, with remarkable results. Instead of fifty-nine probable cases, only one case of tetanus has been observed in six years.

Health of Rural Populations

The *Bulletin de l'Organisation d'hygiène de la Société des nations* is publishing a series of studies dealing with the health of rural populations. These studies deal in part with curative medicine, but the most interesting phase is that dealing with preventive medicine. The prevention of diseases among rural populations involves a study of their working conditions, nutrition and housing, the installation of water pipes and the construction of sewers, all that concerns the life of the peasants and the inhabitants of small isolated localities. It is desirable that in France more attention be given to the question of sanitation in the country. The population is decreasing there, and the exodus of young people to the cities, with its regrettable social consequences, could be discouraged if rural regions were more healthful.

Personals

Professor Herissey, who holds the chair of biologic chemistry at the Faculté de médecine of Paris, and Prof. Léon Binet, who occupies the chair of physiology at the same institution, were elected to the Académie de médecine recently. Binet has published much material on varied subjects, including the functional exploration of the lung and asphyxias, and is the author of a classic treatise on physiology.

Prof. Marc Tiffeneau, who succeeded Professor Roussy as dean of the Faculté de médecine of Paris, has been elected a member of the Académie des sciences.

The Académie de médecine has lost Professor Nicolas, one of its most eminent members, who died in Nancy at the age of 78. He was permanent secretary of the Association of Anatomists of French Speech.

The Status of Sickness Insurance

The German ministry of labor, which controls the sickness insurance organizations, published a survey on the status of the legalized sickness insurance organizations in the year 1938. The number of groups showed a further decrease; as has been stated before in these letters, efforts are being made to reduce the number of groups so as to save on the cost of administration. According to the latest official figures there exist in the old territory of the reich 4,481 legalized sickness insurance groups, with 21.5 million members, and twenty-eight supplementary groups, with approximately 2.2 million members; that is, in all there are about 4,500 groups, with a membership of 23.7 millions. The year 1938 closed with a small financial surplus, which, however, was so slight that the financial status of the insurance groups must be kept under constant control. Regarding the question of the functions of sickness insurance, the ministerial reviewer points out that today the incidence of disease should not be estimated merely from the standpoint of sickness insurance, because the incidence of disease is today a question which concerns general economics and which must be estimated in its general effects. Cases of malingering represent a burden for the insurance funds by causing unnecessary expenditures and thus preventing the use of funds for improvements in services or reduction of premiums; moreover, such cases deprive the economic life of the nation of working forces. He further stresses that

sickness insurance has the task of giving early and thorough help also in the form of prevention and prophylaxis. Efforts should be made to reduce the cases which concern only trifling matters but which take up a relatively large part of the disbursements. These funds could be used for more important functions, also in the sphere of prophylaxis. The reviewer admits that this aim, namely the reduction of minor cases, cannot be accomplished by legal measures but requires educational efforts.

The task for 1939 is the creation of a sickness insurance organization for greater Germany, that is the incorporation of the newly acquired territories, Austria and the Sudeten region.

Unrestricted Practice Abolished

By a new law a period of quackery is terminated in Germany, or at least its end is within sight. This closes a period which was initiated in 1869 as the result of a false interpretation of liberalism. The historic paradox of this entire development is that physicians and the Berlin Medical Society under the leadership of the ophthalmologist Professor von Graefe and of Virchow worked at that time for the so-called kurierfreiheit (free practice of medicine). During the many ensuing decades the medical profession did not succeed in effecting improvements and in introducing better conditions for the German people; anybody who wanted to could "cure." The national socialist movement has given attention to these problems ever since it came to power. Care was taken that the nature cure practitioners, the so-called heilpraktiker, were under some form of control and that the severest abuses were removed, but those who were permitted to remain received certain assurances and it may be said that unscientific "therapeutics" was promoted and protected by the highest authorities. Now, however, under the new law, a decisive step has been taken. The essential provisions are as follows: A person practicing medicine who does not have the "approbation" as a physician must have a permit. The practice of medicine in the meaning of this law is every professional or occupational action for the diagnosis, cure or alleviation of diseases, illnesses or bodily defects in human beings. Whoever has been a professional practitioner of medicine may continue if he secures a special permit, under the professional designation "heilpraktiker" (lay practitioner), but in the future, that is for new candidates, this permit is given only in exceptional cases. However, one concession allows that a person who demonstrates by special accomplishments his capacity for practicing medicine may, by a dispensation of the ministry, be admitted to the study of medicine on easier terms so far as he proves his aptitude for this study. Training schools for nature medicine must be closed. Violations of this law are punishable by imprisonment for as long as one year as well as by a fine.

The lay practitioners must be members of their organization, that is of the "German society for lay practitioners." A permit may be granted under exceptional conditions for the practice of the art of healing by a person not a physician who has not been active in this sphere heretofore but who wishes to be in the future. The decision as to whether such a permit is to be granted is rendered by a committee of experts of the reich's ministry of the interior consisting of two physicians and two lay practitioners. Before the committee renders the decision, the candidate must subject himself to a test of his qualifications and efficiency as a practitioner in a hospital designated by the ministry. The physician in charge of the hospital, in consultation with a lay practitioner, supervises this examination, which may last as long as six months. If the permit is granted at this time, the candidate is given the title "physician of nature medicine." Thus a title with the component "physician" is applied for the first time to a person who has not completed a regular course of medical studies. These persons are also subject to the reich's regulations for physicians, just like the regular physicians. Only a small number of persons will be affected by this.

According to another concession, "Whoever helps his fellow men in an unselfish manner to prevent or cure diseases should not be hindered in doing this"; thus it seems that if a person does not take payment for it he is permitted to practice quackery. The leader of the physicians of the German reich emphasizes that the lay practitioners did much to promote the natural therapeutic methods but that the national socialist state has already succeeded in producing a synthesis between school medicine and the natural therapeutic methods. He expresses the opinion that the majority of physicians now are acquainted with the biologic methods of treatment and are making adequate use of them. Thus a special group of nature cure practitioners is no longer necessary. He also said that in the future the lay practitioners would number about 5,000 instead of the present 13,000 and that, on the basis of the new law, this group would not receive new additions and thus would be automatically abolished within a few decades. Some therapeutic performances will not be affected by the regulations of the new law, especially those of a more mechanical nature, for instance the determination of visual acuity by the optician and the making of orthopedic apparatus.

In the future it will thus be entirely clear who, besides physicians, may practice medicine as a profession or a trade in Germany. Since the belief in miracles and superstitions is widespread among the people, this thorough regulation will no doubt produce favorable results.

Marriage and Birth Increases

Statistics on the growth of the population show a favorable development for 1938. The frequency of marriages was high, about 22,000 more marriages having been contracted in 1938 than in 1937 in the old reich. This increase is all the more noteworthy because the male youth of the years with a falling birth rate has now attained marriage maturity. An exceptionally large increase of marriages is reported for Austria (22,000 in the third quarter of 1938, more than twice as many as in the corresponding period in 1937). A similar fact was observed during the earlier period of the Nazi régime because of the easements, like loans, granted to newly married couples.

The increase in the birth rate received a new impetus in the second half of 1938; 7.7 per cent more children were born in the third quarter of 1938 than for the same period in 1937. The total number of births in 1938 may be computed to be 1,340,000 for the old reich; that is, 19.6 per cent per thousand inhabitants. If to this are added about 91,000 births in Austria and about 52,000 in the Sudetenland, the total number of births for the whole of present day Germany amounts to 1,484,000. This number is by 165,000, or 10 per cent, short of the 1,650,000 necessary to maintain population and army needs.

School for Leaders of the Red Cross

A school for leaders of the German Red Cross, opened at the end of February near Berlin, is to serve chiefly for the training of the leaders of the chief sections of the different district stations of the Red Cross. In addition there exist nine district schools which train the file leaders in courses lasting six days. About thirty persons are usually accepted for each of these six day training courses. In the opening address the president of the German Red Cross, brigade leader Dr. Grawitz, explained that in 1938 the Red Cross of all Germany had been completely reorganized. In the spirit of national socialism a new soldierly organization was formed out of the more than 9,000 societies that existed earlier. He pointed out that this new organization had proved its worth at the time of the union with Austria, at the time of the occupation of the Sudeten districts, in the care of Sudeten-German refugees and in the sanitary service of the workers who constructed the fortifications on Germany's western borders.

Tuberculosis and the Government

In view of strong representations by a deputation and outspoken criticism of the government's policy regarding tuberculosis by Dr. H. W. Palmer, until recently superintendent of a large sanatorium, the government in New South Wales is considering a proposal to provide special facilities for the accommodation and care of patients with early tuberculosis.

The recommendations, if put into effect, would come near to solving the tuberculosis problem but for the fact that most of the patients with the early form in need of the care proposed have yet to be found. Despite the thousands of persons slightly afflicted, clinics, sanatoriums and hospitals receive few patients who have not reached an advanced stage. This is thought to be due to certain limitations to which the agencies responsible for notification are subject. The general practitioner, for instance, when reporting a case of tuberculosis has to fill in elaborate forms, forwarding with them a short history of the case, a description of the present condition of the patient and an outline of the treatment advised, to assist the tuberculosis division to decide how to act. All this takes considerable time, for which the physician receives little or no reward. Then, practitioners are often too busy to find the time or take the trouble necessary to test a patient thoroughly for signs of tuberculosis. Many others lack expert knowledge and experience necessary to diagnose a disease the early symptoms of which are elusive. Furthermore, a considerable number of physicians are reluctant to brand their patients with the social stigma of tuberculosis. No wonder therefore that few cases of early involvement are reported.

Notifications from clinics are almost as disappointing, although for other reasons. Fear of losing his means of livelihood keeps a patient away until his disease is so advanced that, on an average, he has infected ten other persons. When he does present himself, note is made of his contacts, who are called on by a visiting nurse. It is by testing these that the clinic obtains the bulk of its patients, including the few patients in the early stages who never should have been infected. According to the most optimistic estimates, scarcely more than 20 per cent of all patients are in these stages. As a means of combating this state of affairs, it has been suggested that a mobile clinic be instituted which would attempt to locate possible cases of early involvement through the general practitioner.

Frequently the wage earner cannot afford to leave his wife and children, who depend on him. Consequently after he has received the distressing news that he is afflicted, work and worry combine to aid the progress of the disease, which develops rapidly until it is incurable and the sufferer may have infected others. If he goes into a sanatorium he gets a pension of £1 a week after a certain amount of departmental delay, but this sum is not nearly sufficient to maintain his wife and family, who are probably already infected and need good food. Official figures show that 50 per cent of the invalid pensions granted to women in New South Wales between the ages of 25 and 30 (the child-bearing ages) are for tuberculosis.

Many and frequent recommendations have been made to both the state and the commonwealth government to improve this state of affairs but nothing has yet been done to make them effective. That such an omission is a penny wise, pound foolish policy is proved by the fact that last year New South Wales had to spend £60,000 on tuberculosis, ineffectively, in addition to subsidies to various hospitals. It is evident that the tuberculosis problem can be solved only by making it possible for the patient in the early stages to receive treatment, and by insuring that a patient with the arrested form will not have a relapse. Any money spent in these directions will be more than offset by a reduction in the lost legion of expensive incurable patients.

Preventable Disease

That the list of diseases which were positively preventable was ever increasing and that, although the causes of many of the world's most virulent diseases had been known for years, they had not yet been stamped out were facts stressed by Sir Alfred Webb-Johnson, surgeon to Queen Mary, delivering the Anne MacKenzie memorial oration at the Australian Institute of Anatomy. He said that an expenditure equal to that being devoted to war purposes would be necessary to eradicate them and that, if only peace could be assured and the vast sums expended on armaments could be devoted to the improvement of housing and nutrition, the provision of better water supplies and all the other basic needs of health, the results might be better for mankind. He also mentioned the problem of the airplane as a possible means of rapid spread of infective disease from one country to another. Cholera, yellow fever and trypanosomiasis, which formerly were held in check by ocean barriers, could now be spread by air travelers, and this necessitated a stringent watch and control by medical authorities.

Sir Colin MacKenzie Memorial

Before the oration was delivered, the minister for health, Senator Foll, unveiled a memorial tablet which had been erected in the Institute of Anatomy by Lady MacKenzie to its founder and first director, Sir William Colin MacKenzie. Senator Foll said that the institute was its own memorial to the active life of its founder and that the late Sir Colin's work would become more and more important in the future as investigators made use of the material which he had provided

Protection Against Air Raids

Preparations for the protection of the civilian population in air raids have commenced. Throughout the country groups of men and women are being trained in first aid and decontamination duties, and physicians, police and hospital employees are being instructed in antigas measures. Some arrangement too has been made for emergency organization of essential services. There is a pressing need, however, for greater cooperation with the medical profession and for extension of facilities for the collection, evacuation and treatment of such casualties as do occur.

Marriages

JOHN KENNETH SOKOL, Spencer, Iowa, to Miss Ruth Ashley of Grand Forks, N. D., at Evanston, Ill., April 1.

DUNCAN I. C. KING, Hendersonville, N. C., to Miss Virginia Marie Braznell of Miami Beach, Fla., March 4.

CHARLES LAWRENCE WHITTEMORE to Miss Amy Dumbell Villalonga, both of New York, May 24.

MARCUS EUGENE MORRISON to Miss Sara Katherine Harlan, both of Corinth, Miss., recently.

ROBERT J. HAUSCHEL to Miss Izetta Pointdexter, both of Bremerton, Wash., February 14.

CHARLES W. MCLAUGHLIN JR., to Miss Beatrice Remeirs, both of Omaha, January 14.

JAMES OLIVER WARREN to Miss Sue Thrasher, both of Welch, W. Va., March 12.

WILLIAM CATLETT LITTELL to Miss Alma Bordelon, both of Opelousas, La., recently.

RICHARD T. HAVERSTOCK to Miss Evalyn Moore, both of Seattle, February 25.

JOSEPH DAVIS to Miss Ella Rose Goldberg, both of Louisville, Ky., recently.

DAVID J. WERNER to Miss Loyola Host, both of Milwaukee, February 18.

Deaths

Daniel Nathan Eisendrath ⊕ once a distinguished surgeon of Chicago and more recently a resident of Paris, France, died in Paris, June 1, following an operation. Dr. Eisendrath was born in Chicago, Nov. 8, 1867. He received his bachelor's degree from Johns Hopkins University in 1889 and the degree of doctor of medicine from Northwestern University Medical School in 1891. After study abroad he began the practice of medicine in Chicago. He was assistant clinical professor of surgery at Rush Medical College and attending urologist at Michael Reese Hospital. He left the United States to establish a permanent residence in France in 1930, qualifying as a practitioner under the laws of France and becoming consulting urologist to the American Hospital in Paris. He was the author of a textbook on clinical anatomy published in 1903, a textbook on surgical diagnosis, and also with H. C. Rolnick author of "Clinical Urology," the first of the several editions of which appeared in 1928. He was also the author of a number of monographs and scientific contributions devoted to surgical subjects. During the World War he served as captain in the medical corps. He was a member of the Chicago Surgical Society, the Western Surgical Association, the Chicago Urological Society and the American Urological Association. He was a fellow of the American College of Surgeons and a member of the Congrès de chirurgie (France) and of the Société belge d'urologie. For some years he served as Paris correspondent of THE JOURNAL.

Alfred Friedlander ⊕ Cincinnati; Medical College of Ohio, Cincinnati, 1895; since 1919 professor of medicine and since 1934 dean, University of Cincinnati College of Medicine; member of the American Pediatric Society; fellow of the American College of Physicians; served during the World War; chief of the medical staff in charge of all medical and educational work of the Cincinnati General Hospital and formerly superintendent; on the staff of the Hamilton County Home and Chronic Disease Hospital and the Hamilton County Tuberculosis Sanatorium; president of the Heart Council of Greater Cincinnati; author of "Hypotension," published in 1927; aged 67; died, May 28.

A. Donaldson Smith, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1889; engaged in African exploration with a scientific staff provided by the British Museum; exploration between Berbera and the Nile, and in Mongolia; was awarded the Cullum gold medal by the American Geographic Society, Kane gold medal by the Philadelphia Geographic Society; honorary fellow of the Royal Geographic Society, which awarded him the Patron's Medal; author of "Through Unknown African Countries"; aged 74; died, February 18, in the United States Naval Hospital.

Ida Josephine Brooks, Little Rock, Ark.; Boston University School of Medicine, 1891; president of the Arkansas Homeopathic Board of Medical Examiners; formerly lecturer and instructor on social hygiene and associate professor of psychology and psychiatry at the University of Arkansas School of Medicine; at one time acting assistant surgeon in the United States Public Health Service, health director and psychiatrist of the city public schools and psychiatrist of the juvenile court; aged 85; died, March 13, in St. Vincent's Infirmary of pneumonia following a fracture of the hip.

Frank Wilbur Foxworthy, Miami Beach, Fla.; Medical College of Indiana, Indianapolis, 1897; at one time a practitioner in [illegible] as on the staffs of the Methodist [illegible] Hospital and consulting physician to the board of education; served during the Spanish-American War and was awarded the Congressional Medal for valor in action; associated with several insurance companies; author of "Life Insurance Examination," published in 1923; formerly on the staff of the Victoria Hospital, Miami, and St. Francis Hospital; aged 65; died, March 15, in Florence, Ala.

Edward Jay Bernstein, Detroit; University of Maryland School of Medicine, Baltimore, 1887; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; at one time professor of ear, nose and throat, Woman's Medical College, Baltimore; at various times attending ophthalmologist and otolaryngologist to the Bay View Hospital and the Freedman's Hospital, Baltimore, and Borgess Hospital, Kalamazoo, Mich.; formerly consultant to the Grace Hospital; aged 75; died, March 30, of cerebral thrombosis.

Richard Stanwood Benner ⊕ Springfield, Mass.; Harvard University Medical School, Boston, 1903; member of the New England Obstetrical and Gynecological Society and the New England Surgical Society; fellow of the American College of Surgeons; served at various times and capacities on the staffs of the Wesson Hospital, Springfield Hospital and Mercy Hospital, Springfield; Mary Lane Hospital, Ware; Noble Hospital, Westfield, and the Wing Memorial Hospital, Palmer; aged 62; died, March 23, of coronary thrombosis.

Carroll Julian Roberts, Buffalo; University of Buffalo School of Medicine, 1903; professor of medicine at his alma mater; fellow of the American College of Physicians; formerly chairman of the city board of health; aged 58; assistant attending physician to the Buffalo General Hospital; consulting physician to the J. N. Adam Memorial Hospital, Perrysburg, and clinical director of the Edward J. Meyer Memorial (Buffalo City Hospital), where he died, April 6, of pneumonia.

Robert H. Grube, Long Beach, Calif.; Medical College of Ohio, Cincinnati, 1886; past president of the Greene County (Ohio) Medical Society; formerly member of the Ohio State Board of Health; at one time city health commissioner of Xenia, Ohio, and health officer of Greene County, Ohio; for many years on the staff of the McClellan Hospital; aged 82; died, February 23, of arteriosclerosis with hypertension and chronic myocarditis.

Harry Lee Shaw, Sumter, S. C.; Medical College of the State of South Carolina, Charleston, 1891; member and past president of the South Carolina Medical Association; past president and secretary of the Sumter County Medical Society; for many years member of the state board of medical examiners; served during the World War; on the staff of the Tuomey Hospital; aged 73; died, February 18, of cerebral hemorrhage.

Lyman Robert Forgrave ⊕ St. Joseph, Mo.; Central Medical College of St. Joseph, 1899; member of the American Academy of Ophthalmology and Oto-Laryngology; fellow of the American College of Surgeons; on the staffs of the Noyes Memorial and Missouri Methodist hospitals and consultant to the State Hospital number 2; aged 63; died, March 9, in St. Luke's Hospital, Kansas City, of bronchopneumonia.

Charles Courtney Grieve ⊕ Medical Director, Captain, United States Navy, retired, San Diego, Calif.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1901; entered the navy in 1903 and retired in 1929 for incapacity resulting from an incident of service; fellow of the American College of Surgeons; aged 65; died, February 17.

Charles R. Garr, Flemingsburg, Ky.; Hospital College of Medicine, Louisville, 1880; member of the Kentucky State Medical Association; past president of the Fleming County Medical Society; past president of the county board of health; aged 80; died, March 11, in the Good Samaritan Hospital, Lexington, of carcinoma of the rectum.

Hercules R. Webster ⊕ Texarkana, Ark.; St. Louis College of Physicians and Surgeons, 1881; an Affiliate Fellow of the American Medical Association; formerly secretary of the Miller County Medical Society; said to have written the first compulsory vaccination law (Arkansas) adopted in the United States; aged 82; died, February 16.

Herbert Lawrence Strandberg, Carteret, N. J.; University of Maryland School of Medicine, Baltimore, 1916; member of the Medical Society of New Jersey; president of the board of education and formerly member of the borough council; served during the World War; aged 48; died, February 24, of chronic congestive heart disease.

Leo Josephus Crum ⊕ Kalamazoo, Mich.; University of Michigan Homeopathic Medical School, Ann Arbor, 1906; past president of the Kalamazoo Academy of Medicine; served during the World War; aged 56; on the staff of the Borgess Hospital, where he died, March 15, of hypertensive heart disease and acute coronary occlusion.

Claudius James Byrne, Worcester, Mass.; Tufts College Medical School, Boston, 1910; member of the Massachusetts Medical Society; fellow of the American College of Surgeons; aged 54; senior surgeon to the Worcester City Hospital, where he died, March 19, of hypertension with coronary artery disease and nephrosclerosis.

Challon Guy Forsee, Louisville, Ky.; University of Louisville Medical Department, 1905; member of the Kentucky State Medical Association; formerly adjunct professor of surgery at his alma mater; fellow of the American College of Surgeons; on the staff of the SS Mary and Elizabeth Hospital; aged 63; died, March 3.

Philip Frank Bernstien, Brooklyn; Syracuse University College of Medicine, 1917; member of the Medical Society of the State of New York and the American Academy of Ophthalmology and Oto-Laryngology; served during the World War; aged 47; died, March 9, in the Jewish Hospital of heart disease.

Roscoe Conkling Danford, Pana, Ill.; Northwestern University Medical School, Chicago, 1896; member of the Illinois State Medical Society; fellow of the American College of Surgeons; served during the World War; chief, surgical department, Huber Memorial Hospital; aged 67; died, March 30.

Charles David Ryan, Indianapolis; Kentucky School of Medicine, Louisville, 1903; member of the Indiana State Medical Association; served during the World War; formerly connected with the Veterans' Administration; aged 61; died, February 7, of coronary occlusion and mitral stenosis.

John Amos Knapp, Mount Vernon, N. Y.; Bellevue Hospital Medical College, New York, 1888; member of the Medical Society of the State of New York; on the courtesy staff of the Mount Vernon Hospital; aged 84; died, February 2, of arteriosclerosis, nephritis and uremia..

George Wheelock Banning, Lakeland, Fla.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1895; at one time on the staffs of the Mercy and St. Luke's hospitals, Davenport, Iowa; aged 69; died, February 21, in the Morrell Memorial Hospital of cerebral hemorrhage and pneumonia.

W. T. Ryan, Tracadie, N. B., Canada; McGill University Faculty of Medicine, Montreal, Que., 1901; for many years special federal quarantine officer at McAdam Junction; superintendent of the Dominion Government Hospital; aged 61; died, February 16, at Bathurst.

John Walker Wigham, Toronto, Ont., Canada; University of Toronto Faculty of Medicine, 1904; L.R.C.S., L.R.C.P., Edinburgh, Scotland, 1905, L.F.P.S., Glasgow, 1905; on the staffs of the Toronto Western and St. Joseph's hospitals; aged 57; died, February 28.

John Noble Ellison ⊕ Portsmouth, Ohio; Miami Medical College, Cincinnati, 1902; past president of the Hempstead Academy of Medicine; aged 61; on the staff of the Mercy Hospital, where he died, March 30, of septicemia and infection of the knee and foot.

Walter Byrne, Russellville, Ky.; University of Louisville School of Medicine, 1910; member of the Kentucky State Medical Association; secretary of the Logan County Medical Society; served during the World War; aged 53; died, March 18, of heart disease.

Edouard Thompson Anderson, Corpus Christi, Texas; Willamette University Medical Department, Salem, Ore., 1898; member of the State Medical Association of Texas; formerly on the staff of the Spohn Hospital; aged 72; died, February 9, of arteriosclerosis.

John Arthur Funk, Hamadan, Iran, Persia; Columbia University College of Physicians and Surgeons, New York, 1900; for many years a medical missionary; in charge of the Lily Reid Holt Memorial Hospital for Men; aged 65; died, March 5, of myocarditis.

John Henry Downing, Toronto, Ont., Canada; Western University Faculty of Medicine, London, 1902; formerly member of the board of education; aged 70; died, March 10, in the Toronto General Hospital of meningitis following an infection of the ear.

George Pierce Du Bose, Washington, D. C.; University of Virginia Department of Medicine, Charlottesville, 1883; formerly connected with the United States Pension Bureau; aged 76; died, February 7, of cerebral hemorrhage and arteriosclerosis.

Ralph Bartholomew Scheier ⊕ San Francisco; College of Physicians and Surgeons, San Francisco, 1908; medical director of the Canyon Sanatorium, Redwood City, Calif.; aged 58; died, February 25, of adenocarcinoma of the urinary bladder.

Charles Roy Davis ⊕ Detroit; Cornell University Medical College, New York, 1908; fellow of the American College of Surgeons; for many years on the staff of the Grace Hospital and the Parkside Hospital; aged 56; died, March 22, of heart disease.

Orrin Henry Freeland ⊕ Mason, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1897; Spanish-American War veteran; formerly member of the board of education; aged 69; died, March 25, of heart disease.

Tobias M. Uhler, Easton, Pa.; Jefferson Medical College of Philadelphia, 1874; member, past president and secretary of the Medical Society of the State of Pennsylvania; aged 90; died, February 19, in St. Petersburg, Fla., of cerebral hemorrhage.

Claude Porterfield Fox ⊕ Greeneville, Tenn.; University of the City of New York Medical Department, 1888; fellow of the American College of Surgeons; aged 72; chief of staff of the Greeneville Sanatorium and Hospital, where he died, March 7.

Harry Calvin Berger ⊕ Kansas City, Mo.; Harvard University Medical School, Boston, 1915; member of the American Academy of Pediatrics; on the staff of the Children's Mercy Hospital; aged 49; died, March 5, of coronary occlusion.

Edward Everett Bickers, Eminence, Ky.; Kentucky School of Medicine, Louisville, 1898; formerly mayor; past president of the county board of health; aged 66; died, March 14, in the Deaconess Hospital, Louisville, of bronchopneumonia.

John Lester Shawl, Onarga, Ill.; Hahnemann Medical College and Hospital, Chicago, 1902; member of the Illinois State Medical Society; on the staff of the Iroquois Hospital, Watseka; aged 72; died, February 23, of heart disease.

Elisha Miller Robinson, Birmingham, Ala.; Vanderbilt University School of Medicine, Nashville, Tenn., 1885; member of the Medical Association of the State of Alabama; aged 75; died, February 26, of uremia, nephritis and myocarditis.

John Joseph Donoghue, Worcester, Mass.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1904; member of the Massachusetts Medical Society; aged 64; died, March 21, in the Pondville Hospital, Wrentham.

Herbert Kelley Gallagher, Albuquerque, N. M.; Jefferson Medical College of Philadelphia, 1922; at one time health officer of Limestone County, Ala.; aged 42; died, March 15, in St. Joseph Sanatorium of pulmonary tuberculosis.

Howard Leslie Cornell, Los Angeles; Medico-Chirurgical College of Kansas City, Mo., 1902; author of three volumes of the "Encyclopedia of Medical Astrology"; aged 66; died, February 17, of nephritis and hypertrophy of the heart.

Andrew Young Thompson ⊕ Larimore, N. D.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1908; on the staff of the Grand Forks County Hospital, Arvilla, aged 59; died, February 26, in Grand Forks.

John Harding, Perry, N. Y.; University of Buffalo School of Medicine, 1878; member of the Medical Society of the State of New York; formerly village trustee and village president; aged 83; died, February 8, of pneumonia.

Cameron Tyerwhitt Coulter, Malone, N. Y.; Queen's University Faculty of Medicine, Kingston, Ont., Canada, 1913; health officer; served during the World War; aged 54; died, February 15, of coronary occlusion.

Mary Salina Barradell, Chicago; Chicago College of Medicine and Surgery, 1913; member of the Illinois State Medical Society; aged 68; died, March 9, in the Roseland Community Hospital of cerebral hemorrhage.

Ira Jefferson Bush, El Paso, Texas; Louisville (Ky.) Medical College, 1890; member of the State Medical Association of Texas; aged 73; died, March 10, of strangulated umbilical hernia and myocarditis.

George H. Turner, Garrison, Texas; Louisville (Ky.) Medical College, 1892; aged 66; died, February 28, in the City Memorial Hospital, Nacogdoches, of hypertension, arteriosclerosis and bronchopneumonia.

Stanley Frank Wasielewski ⊕ Milwaukee; Marquette University School of Medicine, Milwaukee, 1933; aged 31; died, February 25, in St. Joseph's Hospital of rheumatic heart disease with auricular fibrillation.

Giuseppe Munna ⊕ Freeport, N. Y.; Regia Università degli Studi di Palermo Facoltà di Medicina e Chirurgia, Italy, 1904; served during the World War; aged 58; died, February 10, of coronary thrombosis.

William A. Staton, Coal Fork, W. Va.; Kentucky School of Medicine, Louisville, 1885; aged 78; died, February 14, in a hospital at Charleston of chronic hypertrophic prostatitis and hypostatic pneumonia.

Lemuel Alfred Anthony, Rio Vista, Calif.; Missouri Medical College, St. Louis, 1891; served during the World War; aged 70; died, February 11, in the Veterans Administration Facility, San Francisco.

Gustavus Adolphus, Clearwater, Fla.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1900; aged 69; died, March 3, in the Emory University Hospital, Atlanta, of carcinoma of the left lung.

Robert Ewing Zimmerman, Butte, Mont.; University of Louisville (Ky.) School of Medicine, 1938; intern at St. James Hospital; aged 27; was found frozen to death, February 7, near McIntosh, S. D.

Joel William McDonald, Hot Springs National Park, Ark.; College of Physicians and Surgeons, Little Rock, 1909; served during the World War; aged 57; died, February 16, of mitral insufficiency.

Bureau of Investigation

ZORBIT

A Fake Capitalized at Forty Thousand Dollars

Zorbit, Incorporated, of Montclair, N. J., was chartered in the state of Delaware in November 1937 by William Teetzel, President and Managing Director, with a capitalization of $40,000. The concern sold through the mails a reddish brown powder that when applied to the feet was represented to alleviate the pain of arthritis, rheumatism, neuritis, sciatica and lumbago.

Zorbit seems to be a Canadian fake, for the advertising declared that it "has helped thousands in Canada" and, it was added, is "now available to sufferers in the U. S. A." Such "sufferers," one assumes, are the type that a deceased circus manager described as having a birth rate of one a minute.

"Zorbit is not a cure-all"; no, indeed. It was recommended only for such conditions as those already listed. And it worked "Through the Feet." Starting with the hypothesis that "absorption of medicine is not new," it simply "remained for that eminent Canadian chemist and scientist, W. F. Teetzel, to perfect, after years of painstaking research, a formula that could be readily absorbed into the bloodstream." Result, Zorbit! One learns further from Mr. Teetzel's advertising that the Zorbit formula "was perfected in 1923 after several years research by Mr. W. F. Teetzel, for over forty years a leading pharmacist and chemist in Canada."

The reddish brown powder called Zorbit had the following composition:

Iodine, resublimed	½ part	Senna leaves	4 parts
Cascara bark, powdered	3 parts	Mandrake root	6 parts
Nux vomica	1 part	Sulfur, resumblimed	6 parts
Baking soda	4 parts	Iron carbonate	5 parts

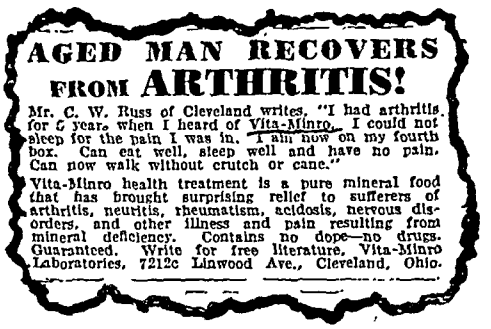
And enough iron oxide to make the powder red!

The instructions for the use of Zorbit were to bathe the feet in warm water, leave them moist, apply a bottle-cap full of the powder to each foot and repeat the treatment on alternate days.

As this powder would *not* be absorbed into the blood stream and certainly would not restore sufferers with rheumatism, arthritis, sciatica, neuralgia or lumbago to "perfect health," the realistic Post Office Department declared Zorbit a fraud and on Sept. 1, 1938, closed the mails to Zorbit, Inc., and also to that "leading pharmacist and chemist," W. F. Teetzel.

THE VITA MINRO FRAUD

Another Fake Is Debarred from the Mails



Harry L. Singletary and Clarence S. Gadsden, both of Cleveland, were, according to a federal report, engaged in promoting a cure-all called "Vita Minro Health Tablets." The business was conducted under such trade styles as "Vita Minro Biochemical Laboratories, Inc.," and "Vita Minro Biochemical Corporation."

The tablets were sold under the claim that they would restore missing vital minerals to the body, cause the glands to function normally, eliminate toxins and dangerous deposits from the blood stream and thereby cure or prevent rheumatism, arthritis, neuritis, neuralgia, indigestion, nervous disorders, dizziness, kidney disorders, low blood pressure, colds, "flu," severe headaches, dropsy—and what have you?

According to the Hon. Calvin W. Hassell, Acting Solicitor for the Post Office Department, in his memorandum to the Postmaster General recommending the issuance of a fraud order, Harry L. Singletary is an ex-locomotive engineer who with his wife operates a boarding house in Cleveland. The name of Clarence S. Gadsden, which also appears in the memorandum, is found in the files of the Bureau of Investigation of the American Medical Association, which indicate that in 1933 he was connected with an imposingly named concern, "The American Biochemical Corporation" of Cleveland, which put out "Paracelsus," a product similar to Vita Minro.

The Vita Minro Tablets, as already suggested, were sold as a cure for whatever ailed one—from soft corns to hardening of the liver! When analyzed by government chemists the tablets were found to be approximately 25 per cent table salt, 56 per cent potassium chloride, 6 per cent potassium sulfate, 7 per cent baking soda and 2 per cent chalk. Although the tablets were claimed to contain all the mineral elements essential to good health, they contained mere traces of iron, calcium and iodine and not any phosphorus!

After the Post Office Department began its investigation of this fraud, Singletary is said to have notified it that he was reorganizing the business so as to abandon the use of the mails and to sell his product through retail drug stores. Such a method of continuing a medical fraud has often been resorted to in the past. It will be interesting to see whether the stipulations of the new federal law governing the sale of "patent medicines" will effectively prevent such circumventions. The old Food and Drugs Act of 1906 limited the powers of the officials to such an extent that a clever faker, by eliminating his cruder falsehoods from the trade package and confining his lies to

other and more potent avenues of publicity—such as billboards, newspaper advertisements, circulars and almanacs—was able to continue his swindle so long as retail druggists cooperated by stocking and in some cases "pushing" the product.

On Sept. 20, 1938, a fraud order was issued against the variously named trade styles of Singletary and Gadsden as well as against the names of Harry L. Singletary and Clarence S. Gadsden themselves.

MISBRANDED "PATENT MEDICINES"

Abstracts of Notices of Judgment Issued by the Food and Drug Administration of the United States Department of Agriculture

[EDITORIAL NOTE.—The abstracts that follow are given in the briefest possible form: (1) the name of the product; (2) the name of the manufacturer, shipper or consigner; (3) the composition; (4) the type of nostrum; (5) the reason for the charge of misbranding, and (6) the date of issuance of the Notice of Judgment—which is considerably later than the date of the seizure of the product and somewhat later than the conclusion of the case by the Food and Drug Administration.]

Heato Salve.—Lucky Heart Laboratories, Inc., Memphis. Composition: Small amounts of zinc oxide and camphor, benzocaine, resorcinol and rosin, in a petrolatum and lanolin base. Not antiseptic when used as directed. Fraudulently represented to be made wholly from roots and herbs, and to heal wounds, boils, burns, "piles," etc., and to give "pep." —[*N. J. 28311; September 1938.*]

Jim Wade Hygienic Powder.—Jim Wade, Inc., Shreveport, La. Composition: Essentially copper sulfate, zinc sulfate and ammonium alum. For irritated mucous membrane, including vaginal, and for "general feminine hygiene." Fraudulent therapeutic claims.—[*N. J. 28307; September 1938.*]

Kandu Vegetable Compound Female Regulator and Builder.—Lucky Heart Laboratories, Inc., Memphis. Composition: Essentially extracts of plant drugs, alcohol, sugar and water, flavored with cloves. Fraudulent therapeutic claims.—[*N. J. 28311; September 1938.*]

Malto-De.—Alberty Food Products, Inc., Hollywood, Calif. Composition: Essentially 79 per cent of sugar, including glucose and cane sugar, with cocoa, malt and powdered dry milk. Fraudulently represented to contain 12½ per cent soluble calcium and phosphorus to each pound and to correct a deficiency in calcium, phosphorus and vitamin D, effect complete growth, well formed bones, sound, hard teeth and eliminate and prevent rickets, etc.—[*N. J. 28310; September 1938.*]

Nod.—Reader Drug Co., Chicago. Composition: 1½ grains phenobarbital and 2 grains of aminopyrine per tablet. Fraudulently represented as a harmless, non-habit forming remedy for all types of nervousness, sleeplessness, alcoholic effects, etc.—[*N. J. 28304; September 1938.*]

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

ADMINISTRATION OF ANESTHESIA IN SMALL HOSPITAL

To the Editor:—The problem has arisen in our hospital as to the best method of handling anesthesia. The hospital is a small one, fifty-six beds, with an active staff of fifteen doctors. Most of the men are too busy to give anesthesia, and if we have a local man as chief anesthetist there are times when he is not available. Also there isn't one who would be willing to give the obstetric anesthesias as well. The question has come up about developing one or two nurse anesthetists and we should like to know what your opinion is of this. Can you give us any idea as to what other hospitals of this size do? We shall greatly appreciate any information you can give us.

M.D., Massachusetts.

ANSWER.—This problem is probably dependent on the persistence of the habit of looking on the administration of anesthetics as a technical procedure requiring little medical knowledge and deserving small financial recompense.

The American Hospital Association, the College of Surgeons, the American Medical Association and other organizations have gone on record as believing in the necessity of the personal direction of anesthesia service by a physician who is interested in and himself trained in anesthesia. Such a director plus a nurse technician are scarcely justified in a fifty-six bed hospital. It would seem, therefore, that with proper financial reward in sight a member of the staff now interested in internal medicine or some other specialty would find it both interesting and profitable to assume in addition the duties of anesthetist to a fifty-six bed institution. Short term postgraduate training is available in many centers. Certainly many recent graduates could be found who have had some training in anesthesia and who would be glad of the opportunity to join such a staff.

SAUERKRAUT JUICE

To the Editor:—Please give me any information you can on the medicinal qualities, if any, of sauerkraut juice. Is there any harm in using it as a saline cathartic? DAN TUCKER MILLER, M.D., St. Louis.

ANSWER.—The following definition and standard for sauerkraut has been adopted by the U. S. Department of Agriculture: "Sauerkraut is the clean, sound product, of characteristic acid flavor, obtained by the full fermentation, chiefly lactic, of properly prepared and shredded cabbage in the presence of not less than two per cent (2%) nor more than three per cent (3%) of salt. It contains, upon completion of the fermentation, not less than one and one-half per cent (1.5%) of acid, expressed as lactic acid. Sauerkraut which has been rebrined in the process of canning or repacking contains not less than one per cent (1%) of acid, expressed as lactic acid." According to Pederson (*Am. J. Pub. Health* **24**:229 [March] 1934) the commercial preparation of sauerkraut is apparently not well standardized in all parts of the country, and a number of samples examined by him were found to vary considerably in chemical composition. However, Pederson reports that excellent quality kraut contains from 2.2 to 2.4 per cent of salt, from 1.3 to 1.5 per cent of total acids as lactic and from 0.2 to 0.3 per cent of volatile acids as acetic. Pederson reports that the first few days of active fermentation is carried on by a group of acid and gas producing cocci, Leuconostoc mesenterioides Van Tieghem, which produce volatile acid, carbon dioxide and alcohol as well as lactic acid. The fermentation is completed by the lactic acid producing rod Lactobacillus pentoaceticus Fred, Peterson and Davenport. Rose (Laboratory Handbook for Dietetics) reports that sauerkraut itself contains, per hundred grams, 1.7 Gm. of protein, 0.5 Gm. of fat, 3.8 Gm. of carbohydrate, 40 mg. of calcium, 10 mg. of phosphorus and 3.3 mg. of iron.

Little information concerning the composition of sauerkraut juice is available. Middleton (*Wisconsin M. J.* **25**:554 [Nov.] 1926) quotes Starke as stating that analyses of eight cans, including seven brands of sauerkraut juice, indicated a salt content of 1.9 Gm. per hundred cubic centimeters or 1.8 Gm. per hundred grams. The juice also may be expected to contain both lactic and acetic acids and to contain the lactic acid bacillus. It is not known, however, whether the bacilli are present in sufficient numbers and viability to be of any real service in cases of excessive intestinal putrefaction.

It is well known that sauerkraut juice has a mildly laxative action for many persons. There is evidence (*Arch. f. exper. Path. u. Pharmakol.* **166**:703, 1932; see also editorial in THE JOURNAL, Nov. 5, 1932, p. 1607) that sauerkraut juice has a stimulating action on active strips of intestine from guinea pigs and rats similar to the action of acetylcholine. It has been further reported (*Arch. f. exper. Path. u. Pharmakol.* **175**:736, 1934) that sauerkraut juice contains histamine and acetylcholine in concentrations of approximately 1:25,000 parts. However, it is stated that the laxative effect of sauerkraut juice is not due to its content of these substances.

Guerrant, Rasmussen and Dutcher report (*J. Nutrition* **9**:667 [June 10] 1935) that sauerkraut juice contains 8.2 mg. of ascorbic acid per hundred cubic centimeters, equivalent to 164 international units of vitamin C. However, the report indicates that these figures are based on the analysis of one can only. Since the vitamin C content of sauerkraut itself has been reported to be highly variable, it is to be expected that the vitamin C content of different samples of sauerkraut juice will also vary widely. Rice reports the use of sauerkraut juice in the preparation of acid milk for infant feeding (*Arch. Pediat.* **51**:390 [June] 1934). Seventy-five infants were fed either fresh or evaporated milk acidified with sauerkraut juice without the addition of orange juice. No scurvy is reported to have developed in any of the children. Until further evidence concerning the ascorbic acid content of different brands of canned sauerkraut juice is available, however, it would seem inadvisable to depend on this product as a source of vitamin C in infant feeding.

TOXICITY OF SHOE DYES

To the Editor:—A patient complains of dimness of vision of the right eye of ten days' duration. The only significant finding in the physical examination was a rather marked optic neuritis in the right eye. Spinal puncture gave entirely negative results. The only significant point in the history was the fact that the patient had dyed a pair of shoes three weeks prior to the onset of her present illness and had worn the shoes daily until the onset of the present illness. The dye used was Shinola Black Dye. Would you kindly inform me whether you have any cases on record of optic neuritis following the use of shoes dyed with this dye.

SAMUEL B. NADLER, M.D., New Orleans.

ANSWER.—The carton of Shinola Black Dye contains the following printed warnings: "Do not wear shoes the day they are dyed. . . . Dye is non-toxic when used on shoes. . . . Caution: Dye is inflammable. Keep it away from fire or flame." Potential toxicity is thus recognized by the manufacturer. The fact that this dye is inflammable precludes the presence of high percentages of polychlorinated hydrocarbons. On burning, this dye yields the characteristic odor of hydrogen chloride, which suggests that some chlorinated hydrocarbon may be present in low percentages. The formula for shoe dyes is likely to change from time to time, so that no warrant exists for precise claims in the absence of careful analysis. However, in times past Shinola Black Dye is believed to have consisted chiefly of nigrosin dye dissolved or suspended in a mixture of methyl cellosolve and denatured ethyl alcohol. The denaturant may have been methyl alcohol representing approximately 5 per cent of the denatured alcohol. In the present instance, if the shoes were not worn within twenty-four hours after dyeing the likelihood of any poisoning is somewhat remote, although methyl cellosolve, if present, may have dried slowly, but absorption of methyl cellosolve through the skin is not thoroughly proved. Reference is made to injuries to the eyes from methyl cellosolve as described by Parsons in the *Journal of Industrial Hygiene and Toxicology* (**20**:124 [Feb.] 1938). Apart from the Shinola product it is to be recognized that some other shoe dyes and leather dressings still contain nitrobenzene and may contain wood alcohol, aniline oil or aniline hydrochloride. Such substances may be distinctly dangerous if shoes are dyed while on the feet or worn immediately after being dyed. Still other shoe dyes may contain orthochlorobenzene or related compounds, the toxicity of which is disputed. If carbon tetrachloride or other chlorinated hydrocarbon is present in appreciable quantities, some opportunity for optic neuritis exists, since ocular damage has been described by Wirtschafter as caused by carbon tetrachloride (Toxic Amblyobia and Accompanying Physiological Disturbances in Carbon Tetrachloride Poisoning, *J. Indust. Hyg.* **16**:4 [Jan.] 1934). On the assumption that the present injury may have been caused by the action of methyl cellosolve or some cellosolve, helpful information might have been gained from careful blood studies such as described in the Parsons reference cited and also in an article by Greenburg and others titled "Health Hazards in the Manufacture of 'Fused Collars': I. Exposure to Ethylene Glycol Monomethyl Ether" (*ibid.* **20**:134 [Feb.] 1938). Queries and minor notes on shoe polishes or dyes have appeared in THE JOURNAL from time to time:

April 27, 1929, page 1471; Jan. 17, 1931, page 212; Aug. 22, 1931, page 557; Sept. 7, 1935, page 819, also, a communication from C. S. Miner appeared in the correspondence column of THE JOURNAL, Feb. 22, 1919, page 593. Dr. R. E. Stifel reported a case of methemoglobinemia due to poisoning by shoe dye (THE JOURNAL, Feb. 8, 1919, p. 395) and there was an editorial on shoe dyes and aniline poisoning July 3, 1926, page 34.

PREGNANCY AND ROENTGEN RAYS

To the Editor:—It has often been stated that fluoroscopic and x-ray examinations of pregnant women may cause fetal monstrosities. I should like to know whether there is any contention for this statement and, if so, whether there is any period in pregnancy when the fetus is sensitive and when not sensitive; also whether x-ray films or fluoroscopic examinations differ in their effect. Would short fluoroscopic examinations be a possible cause for any fetal derangement at any time in pregnancy?

PAUL B. SHUEY, M.D., Long Island, City, N. Y.

ANSWER.—It is well established that fetal monstrosities may result from exposure of the testis, the ovary or the ovum to x-rays and radium, but the dosage must be large. It was learned during early irradiations of carcinoma in pregnancy that abortion resulted or that the child was deformed, aplastic, microcephalic, idiotic or the like, although a few exceptions have been reported. Even the gynecologic application of radium or x-rays damages the child-bearing function of the ovaries, the follicles being permanently affected.

Obstetric roentgenography, in which fluoroscopy almost never is used, does not harm the child or the ovaries; that is, unless an unusual number of films are made.

Only recently have any objections been heard to the foregoing statement, but these are from abroad and are deductions from experiments on plants. Hüssy of Basel found that irradiated beans show no effects in the first generation but that in subsequent ones hypoplastic and deformed beans occurred. Martius of Germany, an experienced roentgenologist, suggests restriction of even the taking of roentgenograms during pregnancy. The greatest danger to the ovum is in the early weeks; therefore the x-ray studies should be postponed if possible until after the fourth month of pregnancy.

X-ray examination for studies on the gastrointestinal and the urinary tract may comprise fluoroscopy as well as films, and in deciding the question of the dangers of the two one should consider the total amount of the active rays used, there being no difference in the quality of the effects.

If the patient is obese or the x-ray man less skilled or if he does not have his eyes accustomed to the dark before he starts his fluoroscope he may give the fetus an overdose of the rays. In such a case the routine films would be safer.

As elsewhere in medicine, idiosyncrasy is to be considered.

POSTMENOPAUSAL VAGINAL ULCERATION

To the Editor.—I have recently seen several cases of ulceration of the vaginal outlet in the fourchette the cause of which I have been unable to determine. In some cases the ulcers were multiple and in others only a single small isolated ulcer was present. In such cases the ulcers are pinpoint to pinhead in size, are rather punched out in appearance and are not covered by any membrane. They are surrounded by an area of erythema possibly 1 cm. in diameter and are tender but not painful. In one case they have been associated with like ulcers on the vaginal wall but in no case has there been any cervicitis or erosion of the cervix. They have occurred only in nulliparous women who are married and past the menopause. Occasionally there has been a slight watery discharge. The thing that has brought them to the attention of their hosts has uniformly been severe discomfort during intercourse. Can you give me any information regarding the possible cause and appropriate treatment?

G. HENRY KNOLL, M.D., Le Roy, N. Y.

ANSWER.—The condition described comes under the category of "senile vaginitis," which is a nonspecific inflammatory lesion of the vagina. This condition usually occurs in elderly women, but it may be observed in young women in whom an artificial menopause has been produced by operation or by radiation therapy. For this reason Davis has suggested the name "postmenopausal vaginitis" as a better term than "senile vaginitis."

Generally after the menopause there is physiologic atrophy of the organs of reproduction. The vagina is particularly affected and is shortened in its anteroposterior diameter and constricted in its lateral diameter, especially at the introitus. The mucosa usually has a glistening appearance because of the absence of normal rugae and atrophy of the squamous epithelium. During coitus the stretching produces superficial tiny lacerations and small hemorrhages. If there is an irritating discharge in the vagina or repeated trauma from intercourse or other cause, the bacteria in the vagina produce an inflammatory reaction in the exposed areas. This results in the formation of superficial ulcers and erosions in the vaginal mucosa both at the introitus and in the vagina itself. Frequently these denuded areas become apposed and adhere to one another, resulting in filmy adhesions. When these adhesions become organized there is firm union between parts of the vagina resulting in obstruction and distortion of the vagina.

The usual symptoms of postmenopausal vaginitis are a watery discharge, severe pain on intercourse, burning on urination, pelvic discomfort and perhaps also pruritus of the vulva.

In most cases of postmenopausal vaginitis, relief can readily be obtained by the administration of estrogen. This substance should be given in two forms: hypodermically and locally as vaginal suppositories. It is best to give from 2,000 to 4,000 international units of estrogen subcutaneously three times a week for about five or six weeks. During this time the patient should insert into the vagina every night a suppository containing 2,000 international units of estrogen. Usually improvement will be noted within two weeks, but treatment must be continued for five or six weeks. The cessation of the annoying symptoms is due to the changes brought about in the vaginal mucosa by the estrogenic substance. Hence there is improvement not only in the subjective symptoms but also in the appearance of the vaginal mucosa. Generally there is a recurrence of the atrophy of the vagina a few weeks after the treatment has been stopped. However, the disagreeable symptoms do not often recur. If they do, another course of treatment, but of shorter duration, should be administered.

PAINFUL HAND

To the Editor:—A Jewish right-handed roofer aged 44 complained of pain, numbness and tingling in the left hand of four months' duration. These symptoms first occurred in the third finger and gradually spread to the fourth and fifth fingers and the hypothenar (ulnar) side of the left hand. The symptoms have been constant, have been increasing in severity and seem to be worse at night, at which time brisk massage of the hand provides sufficient relief to enable him to fall asleep. An hour before the first visit, as he stepped out of a warm automobile into the street, he had a sudden attack of similar pain, which he described as a "sudden shock." This pain began in the third, fourth and fifth fingers at the plantar surface of the left hand and radiated up the anterolateral aspect of the left forearm to the elbow. The patient was plethoric, 5 feet 10 inches (178 cm.) tall, weighing 235 pounds (106.6 Kg.), and had a temperature of 98.6 F. and a blood pressure of 116 systolic, 86 diastolic in both arms. The radial and brachial pulses were equal and palpable with a rate of 80. The rest of the examination was essentially negative except for the affected hand. The left hand was moderately cyanosed, slightly swollen and showed no atrophy or clubbing of the fingers. There was a moderate tenderness over the heads of the fourth and fifth metacarpal bones on the plantar surface, and the left hand was slightly colder than the right. The left grip was definitely weaker than that of the right hand. There were no changes in touch, temperature or vibratory senses. Hoffmann's sign was negative. The urine was normal. The Wassermann and Hinton reactions were negative. Red blood cells numbered 5,090,000, with hemoglobin (Sahli) 86 per cent and white blood cells numbered 7,320; the differential smear was normal. Roentgenograms of the upper left extremity, mediastinum and cervical ribs were negative. Roentgenograms of the teeth revealed an abscess on the third left upper molar (extracted two days after the x-ray film was made). The past history was negative except for a chronic cholecystitis two years before. The patient was diagnosed elsewhere as having rheumatism and he was treated by baking, diathermy and exposures to ultraviolet rays with no relief. My treatment has consisted of alternating hot and cold soaks, baking and massage and aminophylline. The latter gave him the only relief he has ever had. Any help you can give me will be gratefully appreciated.

BENJAMIN SLATE, M.D., Cambridge, Mass.

ANSWER.—It is impossible from the observations submitted to make an absolute diagnosis. Three conditions, however, are to be considered: (1) acroparesthesia (peripheral vascular disease), (2) tumor of the spinal cord at the level of seventh and eighth cervical vertebrae, (3) scalenus anticus syndrome. The following procedure is suggested: Determine the patency of the vessels and the degree of possible vascular dilatation of the blood vessels in the left arm, forearm and hand by intradermal injection of histamine for flare formation in the arm, forearm and hand and by color changes in the dependent and elevated positions of the left upper extremity. A detailed neurologic examination including a manometric study of the fluid for a subarachnoid block is indicated.

The prognosis of the first possible diagnosis is usually fairly good with parenteral administration of tissue extract or intravenous injection of typhoid vaccine or a cervical sympathectomy.

The prognosis of the second possibility depends on the location of the tumor. If it is extramedullary and intraspinal a neurosurgical exploration may reveal a meningioma, cyst or neurofibroma, which can be removed entirely.

If none of these tests reveal any abnormal changes one must consider the third possibility (scalenus anticus syndrome). This condition is one in which the scalenus muscle becomes hyper-

trophied and spastic and by pressure on the subclavian artery may produce symptoms such as the patient complains of, as well as a possible inequality of the radial pulses. This syndrome imitates the effects produced by a cervical rib. The treatment consists of cutting this muscle at its clavicular attachment.

STERILITY AND UNDESCENDED TESTES

To the Editor:—A man aged 26 of Norse descent has been married seven years and has no children. His general health is good but he has bilateral congenital undescended testes, from which he has experienced no ill effects except some embarrassment as a boy at times when he had to undress in the presence of other children. His parents neglected to do anything about this condition while he was a child. He has intercourse with his wife (who is apparently healthy) about once a week; no birth control is practiced. The patient states that erections are good and that orgasm is present with discharge of seminal fluid. His wife has never been pregnant to their knowledge. Examination is essentially negative except for the absence of testes in the scrotum. The penis is of normal size and the inguinal rings are small and contracted. There is no external evidence of the testis on either side. Male secondary characteristics are predominant. Spermatic fluid was examined by a physician six years ago and the patient reports that sperm cells were present with slight motility. In 1938 the fluid was examined again, and the physician reported no sperm cells present. A fresh condom specimen carried to my office by the wife in the vagina revealed no sperm cells. The wife is anxious to have a child. One child was adopted a year ago but was lost through sickness. They have previously consulted several physicians and are fairly well acquainted with the problem faced. The patient would like to know whether it would be advisable to undergo an operation for bringing the testis (one or both) down into the scrotum and whether any beneficial results could be expected from the operation combined with hormone therapy—that is, in regard to his sterility? What chance is there of the testes undergoing malignant change if left where they are? Will his sexual powers become progressively weaker? M.D., Minnesota.

ANSWER.—Although most cases of this type that are relieved by endocrine therapy are treated about the time of puberty, this method should be tried before operation is attempted. The anterior pituitary-like gonadotropic substance should be employed three times a week for a period of about six months.

If this therapy is without result, operation may be considered. The condition is complicated somewhat in this case by the fact that it is difficult to state the exact location of one or both testes. It might be advisable to inject one ejaculatory duct through the prostatic urethra and have an x-ray film made which might give some indication of where the testis is. This procedure should be done only on one side and only by an expert in this field, as an attack of acute epididymitis has followed such an injection. If the testes cannot be located, the only thing to be done is to dissect down and hunt for them. The best operation is probably the one devised by Torek, described in detail in the *New York Medical Journal* Nov. 13, 1909.

It was formerly believed that undescended testes frequently become malignant as a result of pressure from their abnormal position. More extended clinical experience has shown that this is not the case. There is also no reason why the patient's sexual powers should become weaker.

EXCESSIVE SWEATING OF EXTREMITIES

To the Editor:—Will you kindly discuss the nature of and treatment for sweating of the hands and feet.

JOHN J. MOREN, M.D., Louisville, Ky.

ANSWER.—Excessive sweating results from irritation of the nerves, which may occur at any point of the central nervous system. When symmetrically limited to the hands and feet, its common cause is emotional embarrassment, excitement or fear. Evaporation of the sweat makes the hands and feet cold, and knowledge of the fact that one's hands are cold and clammy may add to the embarrassment. The same mechanism causes the axillary sweating seen so commonly in patients during a physical examination. This phenomenon occurs most frequently in adolescents and young adults and tends to improve spontaneously as they grow older.

The patient should be told the cause and encouraged to cultivate self confidence. Soaking the hands in hot water gives temporary relief. Wiping off the perspiration, dabbing the part with an astringent lotion such as alum in water 10 per cent, or from 1 to 7 per cent tannic acid or zinc sulfate in dilute alcohol. After such a lotion has dried, a dusting powder containing salicylic or benzoic acid about 5 per cent may be used. Stronger than any of these is a 25 per cent solution in water of aluminum chloride. This is quite acid in reaction. No soap should be used just before the lotion is applied and no fabrics handled until the hands are dry again after its use. Aluminum chloride, used once in three days, often lessens sweating so that a comfortable condition may be maintained thereafter by using the lotion only once a week.

The most lasting result is to be obtained from divided doses of roentgen rays, 75 roentgens of unfiltered rays once a week until it is seen that the sweating has lessened. Then the treatment should cease and progress of the case should be observed. If the sweating again becomes excessive, more treatment may be given. Treatment should always be stopped short of a full effect, for, as MacKee says, too much dryness is a much more difficult problem than too little (X-Rays and Radium in the Treatment of Diseases of the Skin, ed. 3, Philadelphia, Lea & Febiger, 1938, p. 545).

Excessive perspiration accompanies acrocyanosis, erythromelalgia and erythredema but is only one of the symptoms. The treatment is directed at the cutaneous disease. Tachycardia, tremor or other signs of hyperthyroidism accompanying hyperhidrosis should not be disregarded.

BEZOARS

To the Editor:—I am interested in finding out whether any attempts have been made in the synthetic production of cow bezoars (gallstones). If so, where can I obtain information regarding these experiments? Also whether any work has been done regarding production of any animal bezoars. J. JOSEPH HOROWITZ, M.D., Brookline, Mass.

ANSWER.—The bezoar is a concretion found in the stomach or intestine of man and animals, particularly the ruminants. This concretion is composed of layers of bile salts, soaps, calcium carbonate and phosphate, pigment and proteins around a nucleus of hair or vegetable fibers or a small gallstone. No two natural bezoars are identical in structure or appearance. There is no record available that they have ever been made synthetically.

It is possible to make an artificial gallstone by grinding the ingredients of such stones to a powder and pressing this powder into any desired form, but such artificial stones do not have the laminated appearance of natural stones (Holmes, F. S.: *South. J. Med. & Pharm.* **2**:527, 1847).

CYCLIC VOMITING

To the Editor:—One of twins aged 4 years suffers from cyclic vomiting. A maternal aunt had the same trouble for years in childhood. Are there any new theories relative to cyclic vomiting? What percentage of cases are associated with chronic appendicitis? Will you please send me references relative to the chemical theory versus the allergic theory as the causative factor? M.D., New York.

ANSWER.—There have been many etiologic theories proposed as to the cause of cyclic or recurrent vomiting. The French school, championed by Marfan, has emphasized the presence of acetone bodies in the urine and termed the condition acetonemic vomiting. Occasionally the acetone occurs in the urine before the onset of vomiting. Usually there is acidosis or a reduction in the carbon dioxide combining power of the plasma. Occasionally alkalosis has been reported. This may be explained by the loss of hydrochloric acid associated with the vomiting. Usually the blood sugar is lowered during the height of an attack. Some observers have stated that lowering the blood sugar by fasting may induce an attack. Others have reported inability to produce attacks of vomiting by means of starvation in children known to have this condition. A primary disorder of fat metabolism has been noted, namely an increased combustion of fat. Omitting cream and allowing milk of a low fat content has been said to reduce the frequency of the attacks. Certainly children suffering with this condition have an abnormal metabolism.

Some of the early observers believed that cyclic vomiting was caused by chronic appendicitis. In later years this association has not been stressed, so that the percentage of the association of cyclic vomiting with appendicitis must be small.

In children prone to cyclic vomiting attacks may be initiated by various infections, so that careful examination of these children in each attack should be made. It is conceivable that the predominant symptom of vomiting might mask an attack of appendicitis in such a child.

The allergic theory as an etiologic cause of cyclic vomiting is not stressed in recent textbooks or compilations on pediatric subjects. Jerome Glaser and Mary L. Lerner (*Am. J. Dis. Child.* **53**:1273 [May] 1937) mention allergy among a list of causes of cyclic vomiting. Allergy may manifest itself in symptoms referable to the gastrointestinal tract, as for instance allergic colic from the ingestion of foodstuffs to which the patient is definitely sensitive. However, no one has presented a convincing number of cases in which cyclic vomiting was associated with sensitivity to any specific allergens.

THYROID, PREGNANCY AND SIZE OF BABY

To the Editor:—In a discussion at a series of lectures on obstetrics here the following questions arose: Do thyroidectomized women have larger babies? Is there any evidence that offspring of thyroidectomized women are more apt to show thyroid deficiency? Is it ever justified to give a pregnant woman thyroid for overgain of weight or lowered metabolism except when she is otherwise recognized to be deficient in thyroid? I am sure that the group taking this course sponsored by the state medical society will be grateful for any information that you may furnish.

J. E. JONES, M.D., Lawton, Okla.

ANSWER.—There is good clinical evidence to substantiate the fact that the thyroid gland undergoes some hypertrophy and increased activity during pregnancy which subsides following delivery. Rarely thyrotoxicosis has its origin in pregnancy. The administration of small doses of iodine has been suggested to prevent such a complication. Many clinicians prescribe from 5 to 10 mg. of iodine during pregnancy as a prophylactic measure. The use of iodized salt usually provides sufficient iodine. In goiter regions such a prophylactic measure may be entirely indicated.

There is no good evidence that the offspring of thyroidectomized women are more likely to have thyroid deficiency than the offspring of normal women. Halsted (An Experimental Study of the Thyroid Gland of Dogs, with Special Consideration of Hypertrophy of this Gland, *Johns Hopkins Hosp. Rep.* **1**:373, 1896) reported a series of experiments in which pregnant bitches were subjected to thyroidectomies early in pregnancy and the offspring were born with greatly hypertrophied thyroid glands. A mother with myxedema may give birth to a cretin with a large thyroid gland. Such mothers, however, are of low fertility and do not often conceive. Cretins likewise are of low fertility and do not reproduce. Endemic cretinism does not exist in this country, but a sporadic cretin is occasionally encountered. These cases are due to congenital absence or insufficiency of the thyroid gland. Thyroidectomized mothers apparently do not have larger babies than normal mothers.

The administration of thyroid during pregnancy should be limited to mothers who have definite evidence of thyroid deficiency. The most easily demonstrable evidence of such deficiency is a low basal metabolic rate or symptoms of hypothyroidism. Sufficient thyroid should be admitted to bring the basal rate to the normal level and to maintain it there. Women who gain excessively during pregnancy need not show evidence of thyroid insufficiency. If an excessive gain of weight is not associated with toxemia of pregnancy, it is best controlled by diet and exercise.

GROUP ALLERGENS FOR CUTANEOUS TESTS—SENSITIVITY TO SOLUTION OF FORMALDEHYDE AND GASOLINE

To the Editor:—1. In testing the skin for allergy do pastes of grouped allergens for rubbing into the abraded skin give satisfactory results? 2. Is there a better simple but accurate method? 3. Can desensitization generally be accomplished with commercially available products? 4. What suggestions would you offer in the treatment of (*a*) a laboratory instructor sensitive to solution of formaldehyde and (*b*) a service station attendant sensitive to gasoline?

J. PAUL PROUDFIT, M.D., Washington, Pa.

ANSWER.—1. On the whole, grouped allergens such as those made for rubbing into the abraded skin do not give as satisfactory results as individual allergens. This is because in the process of grouping the concentration of each material used is naturally less than if the material were used separately. If, however, the patient is highly sensitive to some material such as cottonseed, he will give a positive reaction with group allergens as well as with individual allergens. It is frequently difficult enough to obtain positive reactions with single materials in those who are only mildly sensitive.

2. There is no method that is completely accurate, but the best method is to use scratch tests singly and follow them up with intradermal tests in those patients in whom sufficient information has not been obtained by the scratch method. By the use of the scratch method first there will be no danger of any constitutional reactions from the intradermals. Those who make all their tests intradermally run the risk of having constitutional reactions, especially to potent materials such as cottonseed, buckwheat, horse dander, ragweed and glue.

3. Commercially available products can successfully induce hyposensitization. The lessening of sensitivity is a quantitative affair and it is almost impossible to render a patient entirely desensitized. In other words, one cannot completely and permanently desensitize a person to any material to which he is sensitive. However, for all clinical purposes he can frequently be made to be free from symptoms even when exposed to reasonable amounts of the material to which he is sensitive.

4. (*a*) Sensitivity to solution of formaldehyde is probably incurable. However, the use of a respirator or even a simple expedient such as packing the nose with petrolatum might be of help. If the solution of formaldehyde causes cutaneous disorders, rubber gloves should be used.

(*b*) The same procedure would apply to one who is sensitive to gasoline. In the latter, sensitivity to ethyl gasoline, which contains tetra-ethyl lead, must also be considered.

CONGENITAL TORTICOLLIS

To the Editor:—Kindly let me know the accepted treatment for torticollis in a male infant aged 2 months. The child had a normal spontaneous birth and is the second child. The left side of the face and the left side of the head is flatter and not as prominent as the right side. The child keeps its head turned to the right with the chin over the right shoulder and persists in sleeping on the right side. He can turn his head to the left. The left sternocleidomastoid muscle appears to be more prominent than the right one. Will the deformity of the face and head clear up? Does this deformity of the head and face occur with torticollis?

M.D., New York.

ANSWER.—Congenital torticollis is most often caused by fibrous contraction of one sternocleidomastoid muscle. If the condition is mild and the position easily corrected, treatment should consist of repeated stretching to a position of overcorrection, associated with light massage of the tight muscle. After 2 months of age, and particularly when there is already the associated deformity of the face and head, which is often not noticeable at so early an age but becomes more marked as the child grows older, if the torticollis itself has not been corrected more aggressive treatment is indicated. A well padded plaster of paris cast should be applied to the head and chest, extending downward to the level of the umbilicus and maintaining a position of extreme overcorrection. A cast which is carefully applied, so that there will be no question of pressure sores developing under it, may be left on for six weeks without any danger. The cast should then be bivalved and physical therapy instituted consisting of daily stretching and massage. When this type of treatment is undertaken in the patient younger than 6 months of age, the prognosis for cure is good. In the event that the deformity does recur, an operation will be necessary. This operation consists of exposure of the sternocleidomastoid muscle, either near its attachment to the clavicle or at the tip of the mastoid process. Not only should the muscle be divided but a segment at least 1 cm. in length should be removed. From three to four days after the operation a plaster of paris cast similar to that described should be applied, but not at the time of operation. If the attempts to correct the torticollis by any or all of these measures are entirely successful, the deformity of the face and head will completely disappear. However, if the correction of the torticollis is not obtained until the child is several years older, some residual deformity, particularly asymmetry in the level of the eyes, may persist throughout life.

HYPERTENSION AND ALLERGY

To the Editor:—Please let me know whether any experimental work has been done to prove or disprove that allergy is the cause of essential hypertension.

ADOLPH KROLL JR., M.D., Passaic, N. J.

ANSWER.—There is no available evidence on this point from animal experimentation. Clinically there is a preponderance neither of allergic individuals with hypertension nor of hypertension in allergic patients. Kerppola (Coca and others: Asthma and Hay Fever in Theory and Practice, Springfield, Ill., Charles C. Thomas, publisher, 1931) found asthma in 5 per cent of 200 cases of essential hypertension. Kahn (*M. J. & Rec.* **120**:596 [Dec. 17] 1924) states that hypotension is common in allergic states but that elevation of pressure occurs during an asthmatic attack and speculates as to whether repeated attacks may result in persistent elevation of pressure. This is particularly important in respect to the use of epinephrine.

The most comprehensive statement on the matter is given by Vaughan and Sullivan (*J. Allergy* 8:573 [Sept.] 1937), containing extensive quotations of the current attitudes and giving the results on eighty-one allergic patients studied intensively with regard to clinical allergy, cutaneous tests, leukopenic indexes and blood pressure. They give detailed reports of the cases with some definite evidence of increased pressure when the patients were exposed to substances to which they were allergic. However, most of their patients failed to show this response.

Waldbott (THE JOURNAL, May 3, 1930, p. 1390) reports repeated elevations of pressure in patients repeatedly exposed to allergens or in those acquiring new sensitization. The most recent point of view as expressed by Ragland (*Clin. Med. &*

Surg., January 1938) is that since so many allergic manifestations, such as eczema and angioneurotic edema and hyperesthetic rhinitis, involve local edema, why may not the intima of capillaries and arterioles swell similarly, constituting the foundation for essential hypertension? However, evidence of this relationship is not convincing in general, regardless of the specific cases, and those encountering the hypertensive aspect are not impressed with the allergic basis of the disease.

UNILATERAL EDEMA OF LEG

To the Editor:—A white man aged 30 complains that his left leg becomes tired following a moderate amount of exertion and that his left leg is becoming larger than the right. His past and his family history are negative. On examination the patient is well nourished, and the only positive changes noted were moderately hypertrophic tonsils, marked pyorrhea of the gums and a left leg definitely larger than the right. At the thigh the left side was 2 inches larger in circumference than the right. At the calf of the leg the left side was 1¼ inches larger in circumference than the right. There is no venous or arterial disease of either leg. The bony structures are apparently normal. Reflexes in the two legs are normal and equal. No abnormal reflexes are elicited. There is no pain or tenderness on palpation. I should like to know the possible diagnosis and treatment.

M.D., West Virginia.

ANSWER.—Unilateral, noninflammatory edema of the lower extremity may be due to a chronic progressive lymphatic obstruction in the pelvis, in the retroperitoneal space or in the peripheral lymphatic system. There also may be a congenital anomaly of the lymphatics, such as aberrant or persistent lymph channels which gradually become manifest in later life.

A more frequent cause of unilateral edema, however, is deep venous obstruction; a careful history may elicit an iliofemoral thrombosis following some infectious disease or operation; it is not at all necessary to find enlarged superficial veins in deep venous obstruction. Treatment depends on accurate diagnosis. If the edema is fairly soft and pitting, elevation in bed, mercurial diuretics, such as salyrgan or mercupurin, and restriction of salt and fluid intake will hasten the return of the size of the limb to normal. Focal infection should be eradicated. Elastic support reaching from the toe to the groin must be worn to prevent refilling of the edematous limb when the patient is ambulatory. In nonpitting, hard edema, signs of mechanical obstruction should be looked for. If enlarged lymph glands are found in the groin or in the iliac fossa, a biopsy may be advisable to rule out the possibility of Hodgkin's disease, tuberculosis or glandular metastasis from another source. Roentgen treatment may control the lymphatic hyperplasias. If there is a suspicion of a low grade obliterative lymphangitis from an infected toe nail or from a ringworm infection, this source should be adequately treated. Surgical measures such as stripping of the perivenous lymphatics or establishment of better drainage of lymph into the retroperitoneal spaces may have to be done in carefully selected cases.

DEAFNESS AND PREGNANCY

To the Editor:—Would you please explain the "why" of deafness following pregnancy that has been apparently normal otherwise? Is there any treatment?

M.D., New York.

ANSWER.—The pregnant woman is subject to all those forces which produce deafness in others and in addition suffers from special hazards due to her pregnant state. The query does not give the results of examination of the external auditory canal and of the membrana tympani.

Assuming that there is no impacted cerumen or tubotympanic catarrh or other transitory and correctible deafness, one must assume that the loss of hearing, if severe, is due to a perception or a conduction type of deafness. If of the latter type it will in all likelihood be otosclerosis; if of the former variety it will be due to an auditory nerve or cochlear involvement. Both of these types of hearing disturbance may be seen during and shortly after pregnancy. A mild involvement may be so aggravated that it first becomes noticeable at these times; or the deafness may come rather suddenly in a hitherto normally hearing person. The present opinion is that these disturbances are apt to occur in pregnancy because of profound changes in metabolism and in the activity of the glands of internal secretion at this time.

The treatment of profound deafness aggravated by and occurring during or shortly after pregnancy will depend on the nature of the deafness and its severity. A complete examination and a working diagnosis of the hearing state are essential. Severe deafness will necessitate psychologic handling, training in lip reading and, in suitable instances, the use of a hearing device. Inflation of the ears and nasal operations are, as a rule, not efficacious.

DIFFERENCE IN THE BLOOD PRESSURE IN THE TWO ARMS

To the Editor:—A patient has a blood pressure on the right arm of 158 systolic and 100 diastolic and on the left arm it is 178 systolic and 110 diastolic. There is thus a difference of 20 mm. of mercury (systolic readings) between the right and the left arm. Can you tell me what might cause such a difference and what procedures I might carry out to find the correct diagnosis? I have looked up various authorities but can find no references to this difference in blood pressures on the two arms of the same individual.

M.D., Massachusetts.

ANSWER.—The difference in blood pressure between the two arms is usually a transient finding related to the time interval rather than to any actual difference between the arms. It is a common occurrence in taking the blood pressure if one starts with the right arm to find that the pressure in that arm is higher than it is two or three minutes later when taken on the left arm. Then if one goes back to the right arm one finds the pressure the same as in the left arm or a little lower. The observations are similar if one starts with the left arm.

On the other hand, there may be a real difference between the two arms. An important difference, however, is quite rare and has not yet been adequately explained in most cases except in those with syphilitic aortitis with obstruction to flow of blood into either subclavian artery or as a result of tumor or scar compressing either subclavian, axillary or brachial artery. There seems to be a congenital difference in a few cases which may perhaps be accounted for by a difference in the size or caliber of the vessels, although this has not been confirmed, or more likely a compression of one vessel or the other by an anatomic variation in the relationship of subclavian artery to clavicle and adjacent muscles. It was recognized during the World War, and probably before, that some recruits were able to decrease or obliterate the pulse in one arm by certain movements of the shoulder in an attempt to escape enlistment in the army.

The difference of pressure in the case referred to is relatively slight and if confirmed is probably to be explained on one of the anatomic factors discussed in the absence of evidence of disease. The difference is, however, unimportant.

PELVIC MEASUREMENTS AND LABOR

To the Editor:—A primigravida aged 22, 5 feet 2 inches (157 cm.) tall, has the following external pelvic measurements: anterior superior spines, 24 cm.; iliac crests, 26 cm.; trochanters, 30 cm.; external conjugate, 19 cm. The husband is a big boned man, 6 feet 2 inches (188 cm.) tall. Would you say that there is great likelihood of serious difficulty in labor?

M.D., Ohio.

ANSWER.—The external pelvic measurements are only a rough indication of the size of the pelvic cavity as a birth passageway. Although the diameters listed are somewhat shorter than the average, the pelvic planes need not be much smaller than normal. The depth of the pelvic inlet can be gaged accurately by determining the diagonal conjugate, which is the distance from the outside of the symphysis pubis to the promontory of the sacrum. If this measures more than 12 cm. the inlet of the pelvis is probably sufficiently roomy to accommodate the average size baby. Another indication of the capacity of the inlet is the course of pregnancy. In patients without cephalopelvic disproportion the fetal head usually enters the pelvic inlet about four weeks before the onset of labor. In the event that the head has failed to engage with the onset of labor, a carefully conducted test of labor may be safely carried out in an attempt to evaluate clinically the capacity of the birth canal.

TRICHOMONAS PROSTATITIS

To the Editor:—Can you give me the latest treatment for chronic prostatitis due to Trichomonas vaginalis? A woman presented herself at my office a few months ago with trichomonas vaginitis. I cleared up the condition only to have it recur about six weeks later. At that time I took a prostatic smear from the husband and found numerous pus cells and several active trichomonads in the prostatic secretion. The husband is symptom free.

HAROLD T. GOLDEN, M.D., Herkimer, N. Y.

ANSWER.—The best treatment for prostatitis due to infection from Trichomonas vaginalis is prostatic massage and application of heat to the prostate. The prostate should be massaged twice a week, firmly but gently, with the patient's bladder full. At home the patient can use a hot water prostatic heater for ten minutes each day. The prostate should be massaged until it is free from trichomonas and pus cells, and the patient should not have intercourse with his wife until he has been cured. Perhaps, as an added precaution, it would be best for him to use a condom even after both have been pronounced cured for at least two months in the hope of preventing a recurrence of the infection.

HYPNOTISM IN OBSTETRICS

To the Editor:—Some time ago there was reported in the daily press (I do not have the reference at hand) the case of an obstetric patient (a doctor's wife, I believe) who lost her life in the course of hypnotic treatment preparatory for her labor. Are you in a position to give the true facts concerning this happening? What is the latest opinion with regard to hypnosis in labor? FREDRIC LEWIS, M.D., New York.

ANSWER.—Without the newspaper reference it is not possible to give a clear opinion, but it is not known, psychiatrists say, that any person has ever died from pure hypnotism. It is conceivable that if, in hypnotic sleep, the patient is given tasks beyond the power of the heart, death might result. The dangers lie in the after-effects—hysteria, phobias, hallucinations and more or less permanent disorientations—although many psychologists deny these in toto.

Probably the woman referred to died from some complication—obstetric, medical or surgical—that was hidden by the alleged hypnotic sleep into which she had been cast. In the early days of twilight sleep an occasional rupture of the uterus or hemorrhage proved fatal.

Pure hypnotism was tried in 1821 by Récamier (said to be the inventor of the uterine curet) in general surgery. It is believed that Fauconnet, in 1860, was the first to use hypnotism for labor pains. Toward the end of the last century Bernstein and Charcot interested the world in this form of suggestion, and obstetricians experimented with it too but many did not pursue the practice long; it was difficult and uncertain, and after-effects were feared. Semianesthesia combined with suggestion worked better. In 1921, because twilight sleep gave such "bad experiences," von Oettingen reintroduced hypnosis, beginning the séances as training at the seventh month and culminating them at labor. Others tried to use posthypnotic suggestion, i. e. putting the gravida into a state of hypnotism and suggesting a painless labor at term. Although a measure of success attended these trials, few obstetricians practice the method today (Halban-Seitz, volume 2, page 811, has quite a little information on the subject).

TUBERCULOSIS OF THE SKIN

To the Editor:—One week ago I removed a small cystic mass which involved the skin and subcutaneous tissues in the region of the elbow. The pathologic report was tuberculosis cutis. The mass was first noted two months ago. The patient is in good health otherwise and is about 30 years old. One year ago I removed an anal fistula. There are no other cutaneous lesions at present. What treatment do you suggest for the tuberculosis cutis, both local and general? The scar has healed well but there remains a mass the size of a small pea in the region lying under but not connected with the skin. The original mass was as big as a good sized grape. ARNOLD BOCKAR, M.D., Warwick, N. Y.

ANSWER.—The site of the lesion should be examined with x-rays. It is possible that the skin was secondarily involved from a disease process in the underlying bone. It is generally known that other granulomatous lesions may closely simulate tuberculous ones. Assuming the underlying bone not to be involved, treating the lesion with x-rays may be helpful. General ultraviolet baths cautiously used with the dosage graduated upward may be given. Gold salts, such as sodium gold thiosulfate intravenously, at times improve some kinds of cutaneous tuberculosis. Diets with a low sodium chloride content may be tried. Finally, the general measures that are in standard use in treating tuberculosis other than of the skin should be adopted.

BLOOD SEDIMENTATION IN CHOREA

To the Editor:—Would you kindly discuss sedimentation rate relative to chorea? M.D., Ontario.

ANSWER.—Most observers are in agreement that the blood sedimentation rate is normal in chorea. When there are other manifestations of rheumatic fever along with chorea the rate is usually fast. Indeed, it would seem that a fast sedimentation rate in a patient with chorea should be considered confirmatory evidence of the presence of active rheumatic fever. Pertinent to the question is the evaluation of the association between rheumatic fever and chorea. Gerstley and his associates (Chorea: Is It a Manifestation of Rheumatic Fever? *J. Pediat.* 6:42 [Jan.] 1935) state that chorea may be caused by rheumatic fever but that this is only one of many immediate causes, psychic trauma being considered as more important. More recently, Coburn and Moore (The Independence of Chorea and Rheumatic Activity, *Am. J. M. Sc.* **193**:1 [Jan.] 1937) have agreed with this conception and state further that the presence of a normal sedimentation rate in uncomplicated chorea is strong evidence against the rheumatic origin of chorea.

It would seem reasonable to consider chorea as a symptom complex, and one closely related to rheumatic fever. In so-called pure chorea, without the presence or history of other manifestations of rheumatic fever, the incidence of rheumatic heart disease is low: Jones and Bland (Clinical Significance of Chorea as a Manifestation of Rheumatic Fever, THE JOURNAL, Aug. 24, 1935, p. 571), 3 per cent, Sutton and Dodge (Relationship of Sydenham's Chorea to Other Rheumatic Manifestations, *Am. J. M. Sc.* **195**:656 [April] 1938) 18 per cent. However, a high percentage of patients having chorea do have other manifestations of rheumatic fever at some time. The problem hence becomes one of evaluation of the presence or absence of rheumatic fever during chorea. A fast or abnormal sedimentation rate would indicate that rheumatic fever is active.

UNEQUAL BODY DEVELOPMENT

To the Editor:—Occasionally I find a patient (1) fairly well developed from the hips downward but of poor muscular development about the chest, shoulders, arms and neck or (2) normally developed down as far as the hips but with excessively enlarged legs. Is there any recognized cause for these inequalities and what can be done to correct them? At present I am interested in a patient with the first condition. M.D., Pennsylvania.

ANSWER.—These are questions which do not permit of specific answers but encourage generalization. The millions of persons who are too large in one part of the body (or too small in another) represent physiologic variations from normal. It is hard to know when they represent pathologic states. Acromegaly is recognized as a well defined condition and its cause is known, but the underlying cause of vague deviations from normal as mentioned in these questions is not known.

Much attention has been paid these questions and there are many volumes written on anthropometry. The one most widely referred to is "Human Constitution" by George Draper (W. B. Saunders Company, 1924).

Therapeutic efforts are usually disappointing. Differing results are reported following the use of various endocrine substances. Diet also is often disappointing, for a high caloric diet usually adds weight where it isn't wanted and a weight-reduction diet usually reduces the wrong part of the body. Exercises may be used to develop muscles, but the woman with thin legs doesn't want bulging muscles. Treatment, for the most part, consists in assisting the patient to an understanding of his problem and helping him effect a philosophic readjustment.

THERAPY FOR HYPOTHYROIDISM

To the Editor:—Please explain the use of thyroxine, compound solution of iodine (Lugol's solution) and thyroid in the treatment of hypothyroidism. It is not clear from the literature that I have read how these preparations should be used, separately or combined, in the treatment of hypothyroidism. M.D., South Carolina.

ANSWER.—While iodine is occasionally reported to produce improvement in some cretins, it has no part in the routine management of hypothyroidism. While thyroxine is of great scientific importance, it likewise has almost no part in the treatment of hypothyroidism. It may be of value in rare instances in which there is some uncertainty about whether or not the patient is taking the thyroid medication that is prescribed. To produce its maximum effect, thyroxine should be administered in an alkaline solution and may be given by the oral, intravenous or subcutaneous route. In nearly every case of hypothyroidism the medication of choice is desiccated thyroid, which is cheap, readily obtainable and easy to take. A preparation should be used in which the iodine content is constant.

ACETYLCHOLINE IN PAROXYSMAL TACHYCARDIA

To the Editor:—Will you please inform me regarding the use of acetylcholine in attacks of paroxysmal tachycardia. G. W. POTTER, M.D., Redfield, S. D.

ANSWER.—Acetylcholine or similar preparations have been used since 1925 in the treatment of paroxysmal tachycardia. There is considerable variation in the degree of success reported by different investigators. All are agreed that it is impossible to attain the therapeutic effect without disagreeable and occasionally dramatic side effects. Nausea and syncope, the latter accompanied by cardiac standstill at times, are the most frequent untoward symptoms. Substernal pain and a sense of constriction in the chest are frequently noted, but their significance is not clear. Flushing, salivation and sweating are nearly always

produced when the drug is administered in sufficient dosage to produce any demonstrable effect on the heart or blood pressure.

Since most attacks terminate spontaneously in a relatively short time and do not produce serious cardiac insufficiency, it is neither necessary nor wise to use this drug as a routine for this purpose. In protracted attacks or those occurring in the presence of minor organic heart disease, it might be considered if other means of stopping an attack have been tried unsuccessfully. There would seem to be reasonable doubt about the wisdom of using it in a case in which the tachycardia is a complicating feature of serious organic heart disease because of the occasional gross disturbance the drug produces in hemodynamics. If it is to be used, it should be given in proper dosage (from 20 to 30 mg.) subcutaneously and not intravenously. Atropine should be readily available to counteract serious side effects.

INTRAVENOUS INSULIN

To the Editor:—I would appreciate any information you might give me regarding the rapidity of the effect of the various types of insulin when given intravenously. I would be grateful for a bibliography.

M.D., Michigan.

ANSWER.—Longwell and Ravin (*Am. J. Physiol.* **117**:453 [Nov.] 1936) found that the action of protamine zinc insulin, when injected intravenously into rabbits, did not differ significantly from that of regular insulin given by the same route.

Berg, Gross, McAfee and Zucker (*Proc. Soc. Exper. Biol. & Med.* **32**:1080 [April] 1935) compared the effect of unmodified insulin injected intravenously on the blood sugar of normal and depancreatized dogs. They give references to the published papers of others in which the results of similar studies on men and animals were reported.

Meythaler and Kleineidam (*Arch. f. exper. Path. u. Pharmakol.* **178**:315, 1935) state that in man, following the intravenous injection of unmodified insulin, the fall in blood sugar begins within one minute.

The monograph "Insulin: Its Chemistry and Physiology," by Hans F. Jensen (New York, Commonwealth Fund, 1938) contains an extensive bibliography on this and related topics.

LONG-CONTINUED APPLICATION OF ICHTHAMMOL

To the Editor:—I have been asked by a colleague what effects could be expected from a continuous application to the skin for a period of ten years of ichthammol. Would it be likely to cause excessive pigmentation or some form of dermatitis? F. W. KENNEY, M.D., Denver.

ANSWER.—"Ichthammol is obtained by the destructive distillation of certain bituminous schists, sulfonating the distillate, and neutralizing the product with ammonia" (National Formulary—ed. 6, 1936, page 201). It has a slight antiseptic action as compared with phenol. Through its action as a reducing and exfoliating agent it is of value in parasitic conditions. Even diluted to 10 per cent strength it produces a drying effect on the upper layers of the epidermis. Some skins are easily irritated by ichthammol. Because of its sulfur content, its long continued application might easily produce a chronic dermatitis. Increased pigmentation could result from ten years' application of the drug.

MONOCYTIC LEUKEMIA

To the Editor:—Do the hematologists recognize such a condition as monocytic leukemia, and if so what is the clinical course of the illness and its symptomatology? In a case of chronic aplastic anemia what is the significance of the sudden appearance of from 30 to 40 per cent of monocytes, the patient otherwise doing well clinically?

JACOB L. STEIN, M.D., Brooklyn.

ANSWER.—Monocytic leukemia is rather generally recognized as a disease entity from the hematologic point of view. There is disagreement, however, as to whether or not it can be distinguished from other leukemias on clinical grounds alone. Forkner (*Arch. Int. Med.* **53**:1 [Jan.] 1934) believes that it can be so distinguished because of the presence of swelling with ulceration and necrosis of the mucous membranes of the mouth, whereas only hemorrhages are found in other types of leukemia. In general, monocytic leukemia is acute and runs a brief and often fulminating course similar to other types of acute leukemia. There are usually fever, lesions in the mouth, some lymphadenopathy (mostly cervical) and usually moderate splenomegaly and hepatomegaly.

The appearance of from 30 to 40 per cent of monocytes in aplastic anemia is difficult to interpret. If the absolute number of granulocytes is decreased simultaneously, it is probably a bad sign.

SEDATIVES AND GRANULOCYTOPENIA

To the Editor:—I want to prescribe a mild sedative for a patient in whom severe granulocytopenia developed four years ago while taking pentobarbital sodium, phenobarbital and a tablet containing aminopyrine. Bromides cause a rash, chloral hydrate causes excitement. Would the administration of phenobarbital alone be completely free from danger? Has any case of granulocytopenia been reported which was thought to be due to phenobarbital alone?

M.D., Saskatchewan.

ANSWER.—When granulocytopenia became comparatively frequent, suspicion was directed toward hypnotics and pain-relieving drugs, since their increased use seemed to be concomitant with the increased frequency of granulocytopenia. Certain combinations contain barbital derivatives as well as aminopyrine; it was first thought that the barbital derivatives were the chief offenders. Later it was shown that aminopyrine was the most frequent causative factor. There seem to be few if any cases in which it has been positively proved that phenobarbital in acceptable dosage has caused granulocytopenia.

Since the patient is in need of a mild sedative and is sensitive to so many preparations, it is suggested that carbromal U. S. P. XI (bromdiethyl, acetylurea) be tried. In this drug the small amount of bromine is in "masked form" and probably will not cause a rash.

CONGENITAL SYPHILIS

To the Editor:—Kindly outline the treatment of heredosyphilis in a boy aged 7 years who has not been given any form of therapy. His height is 45 inches (114.3 cm.) and his weight 46¼ pounds (21 Kg.).

M.D., New Jersey.

ANSWER.—The treatment for this patient cannot be outlined with any degree of certainty without knowledge of the manifestations of congenital syphilis which he presents, if any. Does he, for example, have interstitial keratitis? If he does, depending on the duration and severity of the ocular lesion, nonspecific fever therapy might be immediately instituted. Does he have any clinical evidence of neurosyphilis and is the spinal fluid normal or abnormal? Or, on the contrary, does he show any evidence of congenital syphilis other than inactive stigmas and a positive serologic reaction of the blood?

Regardless of the type of manifestations which he presents he certainly should be treated, since no previous treatment has been given. Without further information, however, the best that can be done is to refer the inquirer to the chapter on treatment in the monograph "Prepubescent Syphilis," by Jeans and Cooke, published by D. Appleton & Co., New York, in 1930 or to chapter 28 on the treatment of congenital syphilis in "The Modern Treatment of Syphilis," by Moore, published by C. C. Thomas, Springfield, Ill., in 1933.

REPEATED CURETTEMENTS

To the Editor:—Would repeated curettages under aseptic conditions, with or without pregnancies and in the absence of any infections or inflammations of the uterus, have a tendency to result in sterility or any other harmful effect in the patient? M.D., Chicago.

ANSWER.—No. In recent years endometrial biopsies have been performed repeatedly on patients in the physician's office with harmful results in hardly any cases. Some of these women were sterile before the biopsies were performed and conceived after these minor operations. Of course endometrial biopsies are not as extensive as curettages. However, if a curettement is properly performed—that is, if it is done under aseptic conditions and with gentle removal of only endometrial tissue—there is complete regeneration of the endometrium and no interference with the normal cyclic activity of the endometrium.

INHALATION OF CHROMIUM SALTS

To the Editor:—A man aged 20 has been working as a chrome plater for the past fifteen months. He has had several ulcers on his hands which have healed. He has at no time had any ulcers in his nose. While working he is protected by rubber gloves and wears a respirator. He has had a few attacks of coma while working. He states that he was unconscious for four hours during one of these attacks. He is nervous, and I am inclined to believe that the "so-called comatose attacks" were really hysteria. Could inhalation of chromium salts have an effect on the brain or cause coma? A. J. WEINBERG, M.D., Chicago.

ANSWER.—The action of chromium is almost entirely topical and limited to mucous membranes, the skin or its adnexa. No reference to the occurrence of coma as a direct result of chromium has been found. It certainly is not probable in the absence of other indications of severe chromium poisoning.

Medical Examinations and Licensure

COMING EXAMINATIONS

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, June 3, page 2354.

STATE AND TERRITORIAL BOARDS

ALABAMA: Montgomery, June 20-22. Sec., Dr. J. N. Baker, 517 Dexter Ave., Montgomery.

ARIZONA: *Basic Science.* Tucson, June 20. Sec., Dr. Robert L. Nugent, Science Hall, University of Arizona, Tucson. *Medical.* Phoenix, July 5-6. Sec., Dr. J. H. Patterson, 826 Security Bldg., Phoenix.

CALIFORNIA: *Written examinations.* San Francisco, July 10-13, Los Angeles, Aug. 7-10, and Sacramento, Oct. 16-19. *Oral examinations* (required when reciprocity application is based on a state certificate or license issued ten or more years before filing application in California). Los Angeles, August 7, and San Francisco, Nov. 15. Sec., Dr. Charles B. Pinkham, 420 State Office Bldg., Sacramento.

COLORADO: Denver, July 10-12. *Applications must be filed on or before June 20.* Sec., Dr. Harvey W. Snyder, 831 Republic Bldg., Denver.

CONNECTICUT: *Medical (Regular).* Hartford, July 11-12. *Endorsement.* Hartford, July 25. Sec., Dr. Thomas P. Murdock, 147 W. Main St., Meriden. *Medical (Homeopathic).* Derby, July 11-12. Sec., Dr. Joseph H. Evans, 1488 Chapel St., New Haven.

DELAWARE: Dover, July 11-13. Sec., Medical Council of Delaware, Dr. Joseph S. McDaniel, 229 S. State St., Dover.

DISTRICT OF COLUMBIA: *Basic Science.* Washington, June 26-27. *Medical.* Washington, July 10-11. Sec., Commission on Licensure, Dr. George C. Ruhland, 203 District Bldg., Washington.

FLORIDA: Jacksonville, June 19-20. Sec., Dr. William M. Rowlett, Box 786, Tampa.

HAWAII: Honolulu, July 10-13. Sec., Dr. James A. Morgan, 48 Young Bldg., Honolulu.

IDAHO: Boise, Oct. 3-4. Dir., Bureau of Occupational License, Mr. H. B. Whittlesey, State Capitol Bldg., Boise.

ILLINOIS: Chicago, June 20-22 and Oct. 17-19. Superintendent of Registration, Department of Registration and Education, Mr. Homer J. Byrd, Springfield

INDIANA: Indianapolis, June 20-22. Sec., Board of Medical Registration and Examination, Dr. J. W. Bowers, 301 State House, Indianapolis.

IOWA: *Basic Science.* Des Moines, July 11. Dir., Division of Licensure and Registration, Mr. H. W. Grefe, State Department of Health, Capitol Bldg., Des Moines.

KANSAS: Kansas City, June 13-14. Sec., Board of Medical Registration and Examination, Dr. J. F. Hassig, 905 N. 7th St., Kansas City.

MAINE: Augusta, July 11-12. Sec., Board of Registration of Medicine, Dr. Adam P. Leighton, 192 State St., Portland.

MARYLAND: *Medical (Regular).* Baltimore, June 20-23. Sec., Dr. John T. O'Mara, 1215 Cathedral St., Baltimore. *Medical (Homeopathic).* Baltimore, June 20-21. Sec., Dr. John A. Evans, 612 W. 40th St., Baltimore.

MASSACHUSETTS: Boston, July 11-13. Sec., Board of Registration in Medicine, Dr. Stephen Rushmore, 413-F State House, Boston.

MICHIGAN: Ann Arbor and Detroit, June 14-16. Sec., Board of Registration in Medicine, Dr. J. Earl McIntyre, 100 W. Allegan St., Lansing.

MINNESOTA: Minneapolis, June 20-22. Sec., Dr. Julian F. Du Bois, 350 St. Peter St., St. Paul.

MISSISSIPPI: Jackson, June 21-22. Asst. Sec., State Board of Health, Dr. R. N. Whitfield, Jackson.

MONTANA: *Reciprocity.* Helena, Oct. 2. *Examination.* Helena, Oct. 3-4. Sec., Dr. S. A. Cooney, 216 Power Block, Helena.

NEW HAMPSHIRE: Concord, Sept. 14-15. Sec., Board of Registration in Medicine, Dr. T. P. Burroughs, State House, Concord.

NEW JERSEY: Trenton, June 20-21. Sec., Dr. Earl S. Hallinger, 28 W. State St., Trenton.

NEW MEXICO: Santa Fe, Oct. 9-10. Sec., Dr. Le Grand Ward, 135 Sena Plaza, Santa Fe.

NEW YORK: Albany, Buffalo, New York, and Syracuse, June 26-29. Chief, Bureau of Professional Examinations, Mr. Herbert J. Hamilton, 315 Education Building, State Education Department, Albany.

NORTH CAROLINA: Raleigh, June 19. Sec., Dr. William D. James, The Hamlet Hospital, Hamlet.

NORTH DAKOTA: Grand Forks, July 5-8. Sec., Dr. G. M. Williamson, 4½ S. Third St., Grand Forks.

OKLAHOMA: Oklahoma City, June 14. Sec., Dr. James D. Osborn, Jr., Frederick.

OREGON: *Medical.* Portland, June 20-22. Sec., Dr. Joseph F. Wood, 509 Selling Bldg., Portland. *Basic Science.* Corvallis, July 8, and Portland, Oct. 28. Sec., State Board of Higher Education, Mr. Charles D. Byrne, University of Oregon, Eugene.

PENNSYLVANIA: [illegible] Philadelphia and Pittsburgh, beginning July 5. [illegible]uly 7-8. Dir., Bureau of Professional Licensing, [illegible], 358 Education Bldg., Harrisburg.

PUERTO RICO: Santurce, Sept. 5. Sec., Dr. O. Costa Mandry, Box 3854, Santurce.

RHODE ISLAND: Providence, July 6-7. Sec., Dr. Robert M. Lord, 366 State Office Bldg., Providence.

SOUTH CAROLINA: Columbia, June 27. Sec., Dr. A. Earle Boozer, 505 Saluda Ave., Columbia.

SOUTH DAKOTA: Rapid City, July 18-19. Director, Medical Licensure, Dr. G. J. Van Heuvelen, State Board of Health, Pierre.

TENNESSEE: Memphis, June 15-16. Sec., Dr. H. W. Qualls, 130 Madison Ave., Memphis.

TEXAS: Austin, June 19-21. Sec., Dr. T. J. Crowe, 918 Mercantile Bldg., Dallas.

UTAH: Salt Lake City, June 26-28. Dir., Department of Registration, Mr. G. V. Billings, 326 State Capitol Bldg., Salt Lake City.

VERMONT: [illegible] Sec., Board of Medical Registration, Dr. W. [illegible]

VIRGINIA: [illegible] Sec., Dr. J. W. Preston, 30½ Franklin Road, Roanoke.

WEST VIRGINIA: Bluefield, July 5. Sec., Public Health Council, Dr. Arthur E. McClue, State Capitol, Charleston.

WISCONSIN: *Milwaukee, June 27-30.* Sec., Dr. Henry J. Gramling, 2203 S. Layton Blvd., Milwaukee.

West Virginia March Report

Dr. Arthur E. McClue, secretary, West Virginia Public Health Council, reports the oral and written examination held at Charleston, March 6-8, 1939. The examination covered eleven subjects and included 110 questions. An average of 80 per cent was required to pass. Five candidates were examined, all of whom passed. Seventeen physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
St. Louis University School of Medicine		(1926)	82.5
Long Island College of [illegible]		[illegible]	89.9
New York University	"	[illegible]	87.9
University of Cincinnati	"	[illegible]	83.9
University of Tennesse	"	[illegible]	88.2

Wisconsin January Examination

Dr. Henry J. Gramling, secretary, Wisconsin State Board of Medical Examiners, reports the oral, written and practical examination held at Madison, Jan. 10-12, 1939. The examination covered twenty subjects and included 100 questions. An average of 75 per cent was required to pass. Fourteen candidates were examined, all of whom passed. Thirteen physicians were licensed by reciprocity and one physician was licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Northwestern University Medical School		(1938) 87, 89, (1939)	85
Rush Medical College		(1937)	87
University of Minnesota Medical School		(1938)	88
Marquette University School of Medicine		(1938) 88, 88,	89
University of Wisconsin Medical School		(1933) (1936) 86, 87, (1937) 89, 89,	87,

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
College of Physicians [illegible]	[illegible]go	(1885)	Illinois

* License has not been issued.

Missouri Reciprocity and Endorsement Report

Dr. Harry F. Parker, secretary, State Board of Health of Missouri, reports ten physicians licensed by reciprocity and two physicians licensed by endorsement at the meeting held in Jefferson City, Jan. 12, 1939. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
University of Colorado School of Medicine		(1934)	Colorado
University of Kansas School of Medicine		(1934, 2)	Kansas
Louisiana State University Medical Center		(1938)	Louisiana
University of Michigan Medical School		(1936)	Michigan
University Medical College of Kansas City, Missouri		(1911)	Nebraska
University of Pittsburgh School of Medicine		(1936)	Penna.
University of Tennessee College of Medicine		(1931), (1937)	Tennessee
Vanderbilt University School of Medicine		(1922)	Tennessee

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Washington University School of Medicine		(1928)	N. B. M. Ex.
University of Vermont College of Medicine		(1935)	N. B. M. Ex.

Book Notices

A Dictionary of Food and Nutrition. By Lulu G. Graves, Organizer and Director of Dietary Departments in Michael Reese Hospital, Chicago, Lakeside Hospital, Cleveland, and Mt. Sinai Hospital, New York, and Clarence Wilbur Taber. Cloth. Price, $3.50. Pp. 423. Philadelphia: F. A. Davis Company, 1938.

This book is the first attempt to provide a compendium of terms of interest to students of foods and nutrition. It includes not only definitions of the more common medical and scientific terms related to the science of nutrition and dietetics but also definitions of a number of such uncommon medical terms as acoria, ageusia, addephagia, eupepsia and oligocythemia. Many comparatively unknown foods such as cherimoya, chervil, genipap, grumichama, sapodilla and sapote are listed, often with interesting details as to origin, history and use. The book is complete. It contains in appendix and scattered throughout the text a number of useful tables and a bibliography of books, bulletins and journal articles pertaining to the subjects. Considerable material has been incorporated relative to the nutritive value of the more common articles of diet. Unfortunately the material relating to nutrition is marred by occasional inaccuracies, such as the statement that sulfur-dried apricots contain more vitamin A (instead of vitamin C) than the unsulfured fruit, frequent confusion of food or nutritional value with calory value and the statement that pellagra is believed to be due to the absence in the diet of vitamin G (now identified as riboflavin). For some unknown reason the definitions for caseinogen and casein are given according to British rather than American usage. The customary American terms for the chief protein of milk, before and after the action of rennin, are casein and paracasein, respectively. However, in spite of these inaccuracies, which may be corrected in future editions, the dictionary has many valuable features, which should make it a convenient and useful addition to the reference shelves of physicians, dietitians, home economists and others interested in foods and in the science of nutrition.

Our Sex Life: A Guide & Counsellor for Everyone. By Fritz Kahn, M.D. Translated from the German by George Rosen, M.D. Cloth. Price, $6. Pp. 459, with 41 illustrations. New York: Alfred A. Knopf, 1939.

This volume, published in German in 1937, is an attempt to provide for the average intelligent person the information that every one ought to have. The book is divided into several parts, the first dealing with the sex function, the second with the technic of sex activity, the third with the hygiene of sex life, the fourth with the problems of fertility, the fifth with the disturbances of sex life, the sixth with the diseases of sex life, the seventh with prostitution, the eighth with the sex life of children, the ninth with the sex life of the unmarried and the tenth with the author's solution of the sex problem. The book is well written, is handsomely illustrated and is modern in its point of view. The author is firm for continence during premarital life, although recognizing that 95 per cent of people fail of complete continence. He recognizes that no real solution has yet been offered for the sex problem of the unmarried and that only through sound education is a solution approached.

Précis de technique radiographique. Par P. Porcher, radiologiste des hôpitaux de Paris. Avec la collaboration de A. Juquelier, assistant de radiologie des hôpitaux de Paris. Cloth. Price, 150 francs. Pp. 332, with 302 illustrations. Paris: Gauthier-Villars, 1938.

The extraordinary development of x-ray diagnosis has encouraged the production of a rather large number of diagnostic works without much reference to technical detail. The state of perfection to which the manufacturers have brought their radiographic equipment has permitted a simplification of technic for ordinary radiographic work, which can be learned in a relatively short time by physicians familiar with the anatomic and pathologic detail. For the benefit of the technician and for those physicians who do their own technical work (every physician should know better than his technician how to do this work), this is a valuable book. The first half deals with the radiographic technic of exploration of the skeleton; the second part deals with the viscera, including the digestive tube and its appendages, the urinary and genital tracts and the respiratory tract. Despite the excellence of this book and the wealth of the photographs showing the various positions described, there is one serious fault, which another edition may perhaps correct. It would aid greatly if, in addition to the photographs of the patients in position for the radiographic exposures, there were added reproductions of the ensuing radiographic results. In fact, without such reproductions the value of the work is greatly reduced. Here and there a few roentgenograms are included, but they are relatively few and certainly inadequate. The book is well printed. The photographic illustrations, though small, are effective, and on the whole the work is a desirable addition to the working library of every radiologist and his helpers.

Rheumaprophylaxe und Rheumafürsorge. Herausgegeben von Dr. P. Köhler, Geh. San.-Rat. Leiter der Staatlichen Rheumaheilanstalt und des Sanatoriums Bad Elster, und Prof. Dr. Rud. Jürgens, Stellv. Direktor der Univ.-Klinik für natürliche Heil- und Lebensweisen und Chefarzt des Augusta-Hospitals Berlin. Verhandlungen der Deutschen Gesellschaft für Rheumabekämpfung Stuttgart, 17.—18. IX. 1938 (Sonderausgabe aus Zeitschrift für Rheumaforschung Band I, Heft 10, 1938.) Boards. Price, 8 marks. Pp. 156, with illustrations. Dresden & Leipzig: Theodor Steinkopff, 1938.

The German Society for the Fight Against Rheumatism met in Stuttgart in September 1938. The present volume, the record of the proceedings, was published by Steinkopff as one of a series of books appearing in the past months, all concerned with various phases of the rheumatism problem. Julius Rother of Berlin opened the meeting. He stated the subject for the symposium and set the temper of the talks by warning his colleagues of their deep responsibility to the fatherland in guarding the health of their fellow Germans. Reiter of Berlin outlined a plan under consideration whereby all those interests within the reich which are concerned with rheumatism are to be coordinated. The nation is to be divided into sectors. Statisticians, insurance companies, dentists, clinicians and bacteriologists will take part in the work. The results will be evaluated and the work directed from the central office; thus useless duplication will be avoided. Eighteen medical papers were presented. The diversity of the subject matter does not permit of individual reviews. However, the papers dealt mainly with general considerations of the incidence and prophylaxis of rheumatic diseases. The "focal infection school" was unusually well represented and discussed extensively the probable roles of dental infections and diseases of the upper part of the respiratory tract, the pelvis and the appendix. No new proofs of the focal infection hypothesis were presented, although, as usual, those with conviction regarding this hypothesis needed no further proof. Josenhans insists that much will be accomplished when every German school child vigorously massages his gums with the "zahnigel"—a gum finger cot with rubber bristles! The proceedings are of interest to those who are following the growing concern of the profession with the rheumatism problem. In Germany, as elsewhere, there is increasing realization of the serious sociological problems and the economic ravages of these previously neglected diseases.

Fevers for Nurses. By Gerald E. Breen, M.D., Ch.B., D.P.H., Senior Assistant Medical Officer, The North Eastern Hospital, London. Cloth. Price, $2. Pp. 199, with 21 illustrations. Baltimore: William Wood & Company, 1938.

This book begins with several chapters on the general features, observations to be made and principles of prevention of fevers in general. The diseases are next discussed individually according to definition, cause, incubation period, segregation period, incidence, mode of spread, course, complications, treatment and prophylaxis. The final chapter is on operative procedures. The clear, concise manner of presentation makes for easy reading. Moreover, constant reference to the patient and the nurse bring realism to items which might otherwise be overlooked.

Giperergicheskie reaktsii (v eksperimente i klinike.) Pod redaktsiey D. E. Alperna. Réactions hyperergiques (expérimentales et cliniques.) Paper. Price, 7 rubles. Pp. 240, with illustrations. Kiev: Gosudarstvennoe meditsinskoe izdatelstvo USSR, 1938.

This volume, published by the department of pathologic physiology of the Ukrainian Institute of Experimental Medicine, deals with investigations carried on in the institute into the various phases of hyperergic reactions. The papers are in Russian with a brief summary in French. The volume should prove of interest to experimental workers in this field.

Molding and Casting: Its Technic and Application for Moulage Workers, Sculptors, Artists, Physicians, Dentists, Criminologists, Craftsmen, Pattern Makers and Architectural Modelers. By Carl Dame Clarke, Associate Professor of Art as Applied to Medicine, University of Maryland School of Medicine, Baltimore. Cloth. Price, $4.50. Pp. 308, with 69 illustrations. Philadelphia: Warren-Knight Company, 1938.

This volume is useful as a reference book to sculptors, artists, dentists, criminologists, craftsmen, pattern makers and architectural modelers. It is of inestimable value to physicians interested in moulages for medical record or the production of realistic, natural and comfortable prostheses. Although in his preface the author "freely admits that this text is far from complete," the book is probably the most complete published reference book to be found on the art of molding and casting. Unlike many other persons doing this type of work, who have patented and carefully guarded their "trade secrets," Clarke has given a comprehensive outline of methods and formulas, some of which are a definite improvement on those now employed. The material is arranged in logical and orderly fashion, beginning with a history of molding and casting as applied to medicine and science in general, going on to the subject of where and how to purchase molding and casting ingredients and continuing with all the details of molding and casting simple subjects, all parts of the human body, pathologic specimens and large subjects. Following the section on molding and casting the entire body are sections on moulages of the oral cavity and moulage prosthesis. The detailed and clearly written descriptions make the volume an ideal textbook for amateurs. There are numerous references.

The Emotional Factor in Visceral Disease. By H. G. McGregor, M.D., M.R.C.P., Medical Registrar, Royal Sussex County Hospital. Foreword by R. D. Gillespie, M.D., F.R.C.P., D.P.M. Cloth. Price, $3. Pp. 198, with 4 illustrations. New York & London: Oxford University Press, 1938.

Dr. McGregor has written an interesting, timely and useful little book in which he gives much information and much good advice. It is an excellent idea to show the medical student that, even when he finds organic disease such as peptic ulcer or chronic ulcerative colitis, asthma, hypertension or hyperthyroidism, he must not forget that factors of nerve strain, fatigue, worry, fear, difficulties in adjustment to life or internal psychic conflicts may well be more important in maintaining the disease or producing exacerbations than are the organic changes to be observed in the body. Furthermore, treatment will often be useless unless the psychic factors are recognized and corrected so far as is possible. The author discusses the now well known fact that there is a definite ulcer diathesis or personality which must be recognized and dealt with during all attempts at treatment of the disease. He gives a number of case reports to show that psychic strain is likely to cause flare-ups in the course of chronic ulcerative colitis, and he shows the importance of such strain in some cases of asthma. He gives much good advice about the treatment of the nervous states, and he points out what should be well known, namely that there are only a few physicians who were born with the requisite temperament, understanding and personality to help persons with nervous and psychic troubles. The average physician, who doesn't like these patients and doesn't like to be bothered with them, usually cannot help them, and often he only antagonizes and outrages them and sends them away angry. The book should be read by all internists and by all young physicians starting out in practice.

Crime and the Man. By Earnest Albert Hooton. Cloth. Price, $3.75. Pp. 403, with 64 illustrations. Cambridge, Massachusetts: Harvard University Press, 1939.

This volume is based on a twelve year survey of the anthropology of the American criminal. It is accompanied by a more extensive work giving all the statistical data on which it is based. Much of the material was used as the foundation of a series of lectures before the Lowell Institute. The author recognizes that psychiatry, anthropology and ethnology all have been concerned with crime and that the answer is not yet available. Since the time when Lombroso contended that the skull of the criminal is distinctive, the anthropological approach to the problem has had significance. Some 15,000 criminals in ten states were examined in this study. The book seems to lead to the conclusion that special studies of the relationship of body build to crime and of alleged occupations of criminals to physique and to general sociological status suggest that the type of a criminal's offense is the resultant of several selective forces or agencies. The author finds, for instance, that tall, thin men tend to murder and to rob, tall heavy men to kill and to commit forgery and fraud, undersized thin men to steal and to burglarize and short heavy men to assult, to rape and to commit other sex crimes, whereas men of mediocre body build tend to break the law without obvious discrimination or preference. The first generation American criminals, he finds, are more persistently criminalistic than the foreign born. It is of course significant that a large scientific study of this type should lead to the definite conclusion that there is a criminal type or several criminal types. The author finds that race does not make the human animal criminalistic but that race undoubtedly influences the choice of crime in those organic inferiors who appear in each racial group. He believes that first offenders ought to be segregated and carefully studied and that paroled delinquents should be kept on a permanent reservation. He feels that the only purely environmental, nonbiologic means of crime prevention which has the slightest prospect of success is the training, supervision and education of children from depressed areas and inferior stocks prior to the onset of delinquency. Professor Hooton is a scientist who knows how to write; he has wit and literary style and what he says merits attention.

Clinical Bio-Chemistry. By Ivan Maxwell, M.D., B.S., M.Sc., Lecturer in Physiology and Clinical Bio-Chemistry, University of Melbourne. Fourth edition. Cloth. Price, 22s. 6d. Pp. 343, with 6 illustrations. Melbourne: W. Ramsay (Surg.) Pty., Ltd., 1938.

This edition contains much of the same material as before, with slight extensions in most chapters and the addition of methods for determining serum phosphatase, urinary p_H and urinary vitamin C. As in former editions, no attempt has been made to present a choice of methods with critical discussions on reliability and significance of the results. It is unfortunate that the methods for determining blood and urinary dextrose, nonprotein nitrogen by nesslerization, urea by urease paper, serum calcium and blood uric acid have not been brought down to date. The book contains much factual material of value to the clinician, and each chapter concludes with a short bibliography of clinical interest.

Medicine for Nurses. By C. Bruce Perry, M.D., F.R.C.P., Professor of Medicine, University of Bristol, Bristol. Cloth. Price, $2. Pp. 211, with 11 illustrations. Baltimore: William Wood & Company, 1938.

In his preface the author states that this book "is primarily intended for nurses studying for the Certificate of General Nursing of the General Nursing Council." In the short space of 203 small pages an attempt is made to discuss the diseases of the blood, of all the systems and of the joints and muscles, deficiency diseases, diseases of the skin and acute infectious diseases and to give some advice on the nursing requirement. Consequently there is not enough explanation of the majority of diseases to satisfy even a minimum of curiosity.

Methodik der Hormonforschung. Von Dr. phil. habil. Christian Bomskov, Laboratoriumsleiter der chirurgischen Klinik der Universität Freiburg i. Br. Band II: Ovar (Follikelhormone, Gelbkörperhormon), Hoden/Hypophysenvorderlappen. Paper. Price, 89 marks. Pp. 1,016, with 274 illustrations. Leipzig: Georg Thieme, 1939.

This book deals with the hormones of the ovaries, testes and anterior pituitary gland. Like the first volume, it is a huge compilation of scientific reports, containing a remarkable amount of data which would be obtained with difficulty under ordinary circumstances. Detailed descriptions are given of the physiologic and chemical properties, extraction methods and assay methods of these hormones. The material is presented in great detail and includes practically all methods for extraction of the various hormones, chemical procedures for their purification and synthesis and assay technics that have been published. For this reason it is an invaluable source book for the investigator in the field of endocrinology. The material, however, is not critically evaluated by the author and contains in detail abstracts of numerous reports of questionable value, demonstrating that the author either has little insight as to the actual worth of much of the material or else is merely acting as a collector of data. The volume is probably intended not to be read but only to be consulted. Considerable experience with the material in question is necessary in order to use it properly. The average medical student or physician would derive little benefit from a perusal of the book.

Der Rheumatismus: Sammlung von Einzeldarstellungen aus dem Gesamtgebiet der Rheumaerkrankungen. Herausgegeben von Professor Dr. Rudolf Jürgens, Stellv. Direktor der Universitätsklinik für natürliche Heil- und Lebensweisen und Chefarzt des Augusta-Hospitals Berlin. Band IX: Die Arthroskopie (Endoskopie des Kniegelenks): Ein Beitrag zur Diagnostik der Gelenkkrankheiten. Von Dr. med. Ernst Vaubel, Medizinische Universitäts-Klinik Frankfurt a. M. Band XI: Der akute Gelenkrheumatismus (das rheumatische Fieber). Von Dr. med. Ernst Vaubel, Medizinische Universitäts-Klinik Frankfurt a.M. Band XII: Dermatologie und Rheumatismus. Von Prof. Dr. med. Richard Frühwald, Direktor der Hautabteilung am Stadtkrankenhaus Chemnitz. Boards. Price, 10 marks; 7.50 marks; 4.50 marks. Pp. 64, with 25 illustrations; 124; 52, with 17 illustrations. Dresden & Leipzig: Theodor Steinkopff, 1938.

Since the turn of the century, physicians have learned much about the exact diagnosis of diseases of the joints. Laboratory procedures and many mechanical methods have contributed largely to this increasing skill. Thus, new light on the diagnosis of rheumatic diseases has resulted from studies of roentgenologic evidence, of fluid aspirated from joints, of specimens taken for biopsy and of immunologic data. Arthroscopic examination may now be added to this growing list. This procedure, the direct visualization of the cavities of joints by an endoscope designed for this purpose, should become important for the study and diagnosis of disease of joints, just as cystoscopic, bronchoscopic and gastroscopic examinations have proved of value. In volume IX of the present series on rheumatism, Vaubel has outlined the technic of the procedure, the indications for it and the attendant dangers, and he has described the instrument made for him by Wolf of Berlin. A description of the normal cavity of the knee joint as seen through the arthroscope is included, and also reports of eleven cases of arthritis in which he employed arthroscopic examination. Roentgenograms and descriptions of the arthroscopic appearance of the diseased joints are presented. Sixteen colored drawings are appended, which show clearly the pathologic changes as seen through the instrument. The diseases pictured include rheumatic fever, acute and chronic infection, arthritis, intermittent hydrops, "arthrosis deformans" and synovial lipoma. This book is devoted to the author's own work. The reader must look elsewhere for the history of the development of the method.

Volume XI in the series, on rheumatic fever, is an objective survey of much present knowledge. The introductory chapter deals with the important geographic, climatic and seasonal factors affecting rheumatic fever. This is followed by a section devoted to a review of pathologic and clinical considerations. The remainder of the text deals with prognosis, therapy, diagnosis and pathogenesis. Discussing the pathologic changes of rheumatic infection, Vaubel has presented a review of much of the newer work in this field. In the earliest stages one finds edema of the connective tissues of affected organs, the individual fiber bundles being separated by edema and swollen or replaced by opaque masses which, like fibrin, stain with acidophilic dyes. This lesion, which appears to be caused by a specific injury to the intercellular ground substance in which fibrils are embedded, has been named "fibrinoid swelling" by Klinge. The rheumatic granuloma, or Aschoff nodule, is a lesion belonging to the later course of the disease. In the section dealing with diagnosis a useful chapter is included regarding the electrocardiogram. Although it shows no alteration pathognomonic of the disease, it gives distinct evidence of myocardial injury in at least 62 per cent of cases of acute involvement. The character of these changes is outlined. Vaubel has observed the late effects of rheumatic fever on the joints, clinically and by arthroscopic examination. Correctly, he emphasizes that these do not include progressive, chronic arthritis; the lesions of the joints almost invariably clear without leaving any residue. Regarding prognosis, everything depends on the severity of the cardiac involvement, which, as Vaubel indicates, is far more frequent and more intense early than later in life. Of those attacked between the ages of 11 and 25, it has been shown that only 20 per cent are alive at the age of 40. After summarizing the recent work on bacteriology and immunology in rheumatic fever, Vaubel cautiously concludes that the etiology of rheumatic fever remains obscure. A specific infectious agent has not yet been proved. Evidence for the tuberculous hypothesis is slim and, as to streptococci, the most one can say is that a preceding streptococcic infection probably forms the groundwork for rheumatic fever; the streptococcus, says Vaubel, is not yet proved to be the specific exciter. He points out that those who claim that the lesions of rheumatic fever are a hyperergic response of the organism sensitized to streptococci overlook the fact that similar lesions have been induced in animals by toxins and by direct infection; the allergic hypothesis is not yet proved. The appended bibliography is fairly extensive.

Volume XII of the series is divided into two sections, the first dealing with "skin diseases which occur frequently in rheumatism" and the second with "secondary skin diseases not causally related to rheumatism." No attempt is made to arrange the dermatologic disturbances on the basis of a classification of articular diseases. Under the first of the two headings are found descriptions of certain types of erythema, purpura, urticaria and nodular eruptions which occasionally accompany rheumatic diseases. These are presented in the pedagogic manner conventional to textbooks on dermatology. Included under the first grouping is an interesting description of Freund's "erythrosis," a condition characterized by pigmentation, heat, redness and atrophy of the skin of the digits distal to the terminal phalangeal joints, with marked hyperkeratosis of the nails. This apparently occurs in association with "rheumatoid" or chronic infectious arthritis. In the second section is a division dealing with altered physiologic function of the skin in rheumatic diseases. These include disturbed sensibilities, altered cutaneous capillary pressure, dysfunction of thermoregulation, vasomotor disturbances and altered sensitivity to dietary and bacterial proteins. Some articular diseases are attributed by rheumatologists to focal infection, and dermatologists are likewise of the opinion that some dermatologic diseases are caused by foci of infection. Accordingly, Frühwald included in the text descriptions of alopecia areata, dyshidrosis, eczema, furunculosis, lichen planus, lupus erythematosus, pemphigus vulgaris and pyoderma; all are possibly related to focal infection (although not particularly to disease of the joints). No descriptions of psoriatic arthritis, keratodermia blennorrhagica or Haverhill fever are included. This volume contains some interesting data regarding associated articular and cutaneous diseases but would be much improved by more systematic arrangement.

Big Fleas Have Little Fleas or Who's Who Among the Protozoa. By Robert Hegner, Professor of Protozoology in the School of Hygiene and Public Health of the Johns Hopkins University. Based on Messenger Lectures, Cornell University, 1937. Cloth. Price, $3. Pp. 285, with 127 illustrations. Baltimore: Williams & Wilkins Company, 1938.

Whenever a chemist, a biologist, a physician or any other kind of scientist suddenly appears on the scene with the extraordinary ability to present his knowledge in such a manner as to interest the average reader, he is welcomed with loud shouts of joy and satisfaction. If he possesses as well the extraordinary ability to make sketches that are full of human interest and if he possesses also a sense of humor like that of the renowned James Thurber, he merits a pedestal. Thus we salute Prof. Robert Hegner of the School of Hygiene and Public Health of the Johns Hopkins University, whose Messenger Lectures at Cornell University in 1937 are here elaborated in a mixture of prose and verse, humor and science, such as seldom appears on the medical scene. The book is readable, enjoyable and enlightening; it deserves a tremendous audience.

The Language of the Dream. By Emil A. Gutheil, M.D. Cloth. Price, $3.50. Pp. 286, with 40 illustrations. New York: Macmillan Company, 1939.

The author of this volume was associated with Stekel and is convinced that none of the books thus far available in the field of the dream are sufficiently concrete or instructive for the average reader. He has attempted a different type of presentation, considering first the element of the dream and the basic mechanisms and next the symbols that appear in dreams, the method of interpretation and the relationship of the dream to the neuroses. His concluding chapter, dealing with the psychologic schools, indicates the differences in point of view of the freudian method from that of Adler and Jung. The book is supplemented by a bibliography, a glossary and an index. It is not likely to have much interest for the average lay reader. It will, however, be significant to all workers in the field of psychiatry, to educators and to those especially interested in the scientific significance of the dream.

The Extra Pharmacopoeia (Martindale). Volume II. Published by direction of the Council of the Pharmaceutical Society of Great Britain. In two volumes. Twenty-first edition. Cloth. Price, 22s. 6d. Pp. 1,148. London: Pharmaceutical Press, 1938.

This volume completes the first edition issued under the new ownership. Neither volume has undergone much change in general scope; the first deals with the composition and application of drug products, while this one deals with such ancillary subjects as analysis and assay of medicinal products, foods and waters. The first section is an analytic addendum concerned with substances previously described, the second section is devoted to problems of analytic chemistry and clinical pathology and the last part deals largely with bacteriologic problems. The work is broad in its scope and may well serve as a starting point in many chemical, clinical and bacteriologic investigations.

The Little Doc: The Story of Allan Roy Dafoe, Physician to the Quintuplets. By Frazier Hunt. Cloth. Price, $2. Pp. 302, with portrait. New York: Simon & Schuster, Inc., 1939.

Most of this book, which appeared in the *Saturday Evening Post*, purports to be the authentic life of Dr. Allan Roy Dafoe. The author is widely known as a competent journalist. Physicians will remember the original story of the birth of the quintuplets, which appeared shortly after the great event occurred. The book reflects some of the terrific excitement and the confusion that attended this event. Frazier Hunt dramatizes the event and, best of all, tells the real story of its entrance into the news and of its development into one of the biggest news stories of all time. The extraordinary interest for medicine is not so much in the birth of five babies as in their growth and development. Apparently there is no record anywhere in the history of medicine of five prematurely born infants weighing as little as these five weighed and surviving. The story is worth the time of any reader.

Zur Pathogenese der arteriellen Hypertension unter besonderer Berücksichtigung der Rolle der Nieren und Nebennieren im Mechanismus des weissen Hochdrucks. Von Roald Opsahl. Acta medica scandinavica, Supplementum 92. Paper. Pp. 262, with 17 illustrations. Stockholm, 1938.

Opsahl is of the opinion that pathologic anatomy may still cast much light on the nature of hypertensive diseases and here presents the results of his investigations along these lines. The first part of the book contains a brief description of the physiologic regulation of blood pressure and the mechanisms involved in the production of hypertension. The author divides persistent hypertension into three categories based on whether it results from purely renal, purely extrarenal or combined renal and extrarenal causes. The second and larger part of the book is devoted to postmortem observations with special reference to the state of the heart, the kidneys and the endocrine organs in hypertension. The student of the field may be interested in the data presented on the weights of the endocrine organs in hypertension. Opsahl concludes that renal hypertension is the result of and compensatory to impairment of glomerular filtration. This may be true but is not proved by the evidence presented. Nor, in the light of recent American work, can one agree with the author's skepticism regarding the role of decreased renal blood flow and of substances formed by the kidney in the pathogenesis of hypertension.

Sbornik trudov posvyaschenny XL-letney deyatelnosti Prof. V. N. Tonkova. [Collection of Works Celebrating 40 Years' Activity of V. N. Tonkov.] Cloth. Price, 20 rubles. Pp. 502, twith illustrations. Leningrad: Izdanie voenno-meditsinskoy akademii RKKA im. S. M. Kirova, 1937.

This volume is dedicated to Prof. V. N. Tonkov, head of the department of anatomy in the Military Medical Academy of Leningrad, by his former pupils on the occasion of his completion of forty years of pedagogic activity. The papers deal with problems in human and in comparative anatomy.

Kurzgefasstes Lehrbuch der Physiologie. Von Ph. Broemser, o. Professor für Physiologie in München. Second edition. Paper. Price, 12 marks. Pp. 371, with 198 illustrations. Leipzig: Georg Thieme, 1938.

This is a well organized and well balanced classic textbook on physiology suitable for medical students. It is not exhaustive and yet it is fundamental. No attempt is made to refer to original literature; consequently it will be of little use to advanced students or investigators.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Malpractice: Loss of Finger Attributed to Failure to Remove Fragment of Needle.—The plaintiff sued the defendant, attributing the loss of a finger to his negligence in failing to remove a fragment of a needle therefrom. The trial court entered a judgment of nonsuit and the plaintiff thereupon appealed to the district court of appeal, second district, division 2, California.

The plaintiff was a seamstress and on Saturday, March 2, 1935, she accidentally ran a needle into her right ring finger through the second joint, and a fragment of it became embedded in the finger. She was taken to the office of the defendant, a physician, shortly after noon. The defendant was about to leave his office but stated that he was familiar with this type of case and would have no difficulty in removing the needle. At the time the plaintiff went to the defendant's office her hand was discolored by a dark stain from the material on which she had been working. According to the evidence the defendant did not wash the finger or hand but swabbed the finger with a liquid which he stated was iodine. He tried to locate the needle with a "Zio-Lite" but was unable to do so. He then sent the plaintiff to a dentist in the building who had x-ray equipment for making roentgenograms of teeth. The dentist made a roentgenogram of the finger but it was not clear or distinct. The defendant, however, made an incision in the finger and probed for the needle for about four or five minutes without locating it. He put some gauze in the wound to establish drainage, stitched up the side of the incision and bandaged the finger and hand. He gave the plaintiff a box of pills to relieve pain and sent her home with instructions to come back the following Monday morning in order to have roentgenograms made.

Saturday evening the plaintiff's hand became very painful, and on Sunday efforts were made to reach the defendant by telephone but he could not be located. Her finger and hand had become swollen and in order to relieve the pain the plaintiff cut the bandages. She became feverish and ill. On Monday she was taken to another physician, who found evidence of infection; a roentgenogram was made and the plaintiff was sent to a hospital where the needle was extracted. Her arm became swollen up to the shoulder and eventually an amputation of the finger was necessary.

On behalf of the plaintiff, evidence was introduced tending to show that the leaving of the needle in the tissue in the present case was the primary cause of the infection. It is the usual and ordinary custom in the community, a witness testified, to take a roentgenogram of the finger before it is incised for the purpose of removing a needle, and that when a roentgenogram is faded and the needle is entirely incased in the finger and not visible to the eye it is not the customary and usual practice for a physician to cut and incise the finger, relying on that type of roentgenogram.

On a motion for a nonsuit, the court said, the trial court must assume that all the evidence in the plaintiff's favor is true and every favorable inference fairly deducible from the evidence and every favorable presumption fairly arising from the evidence must be drawn in the plaintiff's favor. Measured by these rules, the court thought that the issues in the present case should have been submitted to the jury. The court was not unmindful of the general rule that in cases of malpractice it must be shown by expert testimony that the damages suffered by the plaintiff resulted from the failure of the defendant to possess and use that degree of care and skill ordinarily possessed and used by physicians and surgeons in good standing in the locality. The testimony of the expert witness in the case, the court thought, was sufficient to meet the requirements of the general rule, considered in connection with the facts established by the lay witnesses. Even in actions for malpractice the jury may consider without the testimony of experts

matters which are within the common knowledge of mankind. It might be well argued, the court said, that it is a matter of common knowledge that a needle accidentally embedded in the finger of a seamstress might cause infection if not promptly extracted, that a clear roentgenogram would be of assistance to the surgeon and that an effort should be made to secure one.

In the opinion of the appellate court, therefore, the trial court erred in granting the motion for a nonsuit and the judgment of nonsuit was therefore reversed.—*Wires v. Litle (Calif.), 80 P. (2d) 1010.*

Autopsy: Right of Coroner to Authorize Autopsy Without Holding Inquest.—Patrick, a fireman employed by the City of Macon, Mo., collapsed and died while fighting a fire. The local physician of the defendant insurance company which insured the city against possible liability under the Missouri workmen's compensation act notified the coroner that the city had insurance on Patrick and that "they ask for an autopsy." Later in the day another physician employed by the insurer performed the autopsy. Patrick's widow sued the insurance company, alleging that it had caused the autopsy to be performed without her consent or knowledge. From a judgment for the widow the defendant appealed to the Kansas City court of appeals, Missouri.

The court of appeals found no merit in a contention that the widow's remedy was exclusively under the workmen's compensation act. This suit, said the court, is based on the theory that the widow has a quasi-property right in the remains of her husband. The wrong of which she complains occurred after the death of the husband, was in no way connected with the cause of his death and could not therefore be cognizable under the compensation act.

The court disagreed with a contention made by the insurance company that the autopsy was legally performed. In Missouri, the court pointed out, a coroner has no authority to order an autopsy except in connection with an inquest to be held before a coroner's jury. No inquest was held in this case and it was evident that the coroner had no intention to hold an inquest, for he testified that the autopsy was performed merely that he might have information on which to make out a death certificate.

The insurance company next insisted that if the coroner believed an autopsy was necessary he acted in his judicial capacity in having one performed, and the defendant insurance company was therefore protected. But, answered the court, a coroner acts judicially only with respect to determining whether an inquest shall be held and not in the "calling or holding of an autopsy." He has no authority to order an autopsy except in connection with an inquest. In the opinion of the court, the jury could conclude from the evidence that even though the coroner sought to justify the autopsy on the theory that it was necessary for him to sign a death certificate, he abused his office in authorizing the autopsy for the purpose of assisting the defendant insurance company to obtain evidence to be used to defeat any claim for compensation to be made by the widow.

For the reasons stated, the judgment in favor of the widow was affirmed.—*Patrick v. Employers Mut. Liability Ins. Co. (Mo.), 118 S. W. (2d) 116.*

Medical Practice Acts: Refusal to License by Reciprocity Graduate of Unrecognized Medical School.—Salowitz attended the Detroit College of Medicine and Surgery for three years, leaving school in 1925 with conditions in certain subjects. He entered the Chicago Medical School in October 1925 and after an attendance of two school years and an internship of one year received a diploma therefrom in June 1928. In June 1927 and in June 1928 he sought to be examined for a license to practice in Michigan, but the Michigan State Board of Registration in Medicine refused to permit him to do so because [illegible] graduated from a school "not on the accredited list as [illegible]." In September 1928 he was licensed after examination in Illinois. In 1933, and again in 1934, he sought a license by reciprocity in Michigan based on his Illinois license. On the refusal of the board so to license him he sought a writ of mandamus from the Supreme Court of Michigan to direct the board to issue the license.

The Michigan medical practice act provides in part as follows:

> The applicant may, at the discretion of the board, be registered and given a certificate of registration if he or she shall present satisfactory proof of the possession of a certificate of registration or license which has been issued to said applicant within the states, territories, districts or provinces of the United States, or within any foreign country, where the requirements for the registration of said applicant at the date of his or her license shall be deemed by said board of registration in medicine to be equivalent to those of this act.

Under this section, said the court, the granting or refusal of registration rests within the discretion of the Board of Registration in Medicine and courts will not interfere with the exercise of that discretion unless the discretion is abused. In the opinion of the court the board in this case had not acted arbitrarily. The general policy of the board for a number of years past had been to grant recognition only to graduates of class "A" medical schools. In establishing the classification of such institutions the board has accepted the recommendations of the Council on Medical Education and Hospitals of the American Medical Association. The board is a member of the Federation of State Medical Boards of the United States, an organization formed to harmonize rules and regulations maintained in the different states and to promote a uniform and harmonious reciprocal relation between states. The results of investigations made of medical schools by the Council on Medical Education and Hospitals of the American Medical Association are available to all state boards through the federation, and this method of procedure is expedient because of the practical impossibility of independent investigation of all medical institutions by each board. The Council on Medical Education and Hospitals has not at any time during the past ten years recognized the Chicago Medical School as a class "A" school. In 1927 and in 1928 the Chicago Medical School was listed by the Council as a class "C" institution and since that date has been refused any recognition at all.

Salowitz claimed, however, that the board had impliedly recognized the Chicago Medical School by allowing a graduate of that school to take the Michigan examination in June 1926. It appeared with respect to that physician, however, that he attended the Detroit College of Medicine and Surgery from September 1909 to May 1913 but was not allowed credit for any of the work because he failed to remove a condition he had received in anatomy during the first year of his medical school work. He then became associated with certain physicians in Detroit and served during the war. Later he attended the Chicago Medical College in 1923 and 1924 and graduated therefrom. But the Michigan board admitted him to examination in 1926 solely on the basis of his work at the Detroit college, the board specifically stating that he was not admitted to examination on the fact of his graduation from the Chicago Medical College.

The court therefore denied the writ of mandamus.—*Salowitz v. Michigan State Board of Registration in Medicine (Mich.), 280 N. W. 737.*

Society Proceedings

COMING MEETINGS

American Association for Thoracic Surgery, Los Angeles, July 5-7. Dr. Richard H. Meade Jr., 2116 Pine St., Philadelphia, Secretary.

American Physiotherapy Association, Denver, June 25-30. Mrs. Eloise T. Landis, 2065 Adelbert Road, Cleveland, Secretary.

American Proctologic Society, Brooklyn, N. Y., June 25-27. Dr. Curtice Rosser, 710 Medical Arts Bldg., Dallas, Texas, Secretary.

Maine Medical Association, Poland Springs, June 25-27. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.

Medical Library Association, Newark, N. J., June 27-29. Miss Janet Doe, 2 East 103d St., New York, Secretary.

Montana, Medical Association of, Butte, June 28-30. Dr. Thomas L. Hawkins, 50 North Main St., Helena, Secretary.

National Tuberculosis Association, Boston, June 26-29. Dr. Charles J. Hatfield, 50 West 50th Street, New York, Secretary.

Pacific Coast Oto-Ophthalmological Society, San Francisco, June 19-22. Dr. C. Allen Dickey, 450 Sutter St., San Francisco, Secretary.

Pacific Northwest Medical Association, Spokane, Wash., June 26-29. Dr. C. W. Countryman, 407 Riverside Avenue, Spokane, Wash., Secretary.

West Virginia State Medical Association, White Sulphur Springs, July 10-12. Mr. Joe W. Savage, Public Library Bldg., Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to members of the Association and to individual subscribers in continental United States and Canada for a period of three days. Three journals may be borrowed at a time. Periodicals are available from 1929 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Preoperative Diagnosis of Gallbladder Disease Through Laboratory Analysis and Fluoroscopic Examination of Gallbladder and Duodenum. W. M. Bland, Tuscaloosa.—p. 350.

Primary Lymphosarcoma of Intestine: Report of Four Cases. C. R. Lafferty, Montgomery.—p. 353.

American Journal of Clinical Pathology, Baltimore

9: 121-256 (March) 1939

Concerning the Method Proposed for Reporting the Serologic Reactions for Syphilis as Positive, Doubtful and Negative. J. A. Kolmer, Philadelphia.—p. 121.

Occurrence of Nonspecific Substance in Guinea Pig Serum Fixed by Antigen in the Wassermann Test. A. S. Giordano and Bonita Carlson, South Bend, Ind.—p. 130.

Guinea Pig Serum in Relation to Prezone and Nonspecific Wassermann Reactions. J. A. Kolmer, with technical assistance of Elsa R. Lynch, Philadelphia.—p. 136.

*Laughlen Test for Syphilis: Comparison with 1,000 Kline, 1,100 Kolmer and 100 Kahn Tests. Regena C. Beck, Richmond, Va.—p. 151.

*Reliable, Sensitive, Simple and Rapid Slide Flocculation Test for Syphilis. L. Y. Mazzini, Indianapolis.—p. 163.

Sedimentation Rate and Leukemoid Reaction in Metastatic Tumors of Bone. D. H. Kaump, Temple, Texas; F. J. Heck and E. G. Bannick, Seattle.—p. 176.

Myeloid Pattern in Pernicious Anemia. E. A. Sharp, E. M. Schleicher and J. W. Wolter, Detroit.—p. 189.

Diagnosis of Trichinosis by Digestion Method: Additional Aid to Diagnosis. F. B. Queen, Denver.—p. 209.

*Spirochetal Jaundice in Buffalo, N. Y.: Report of Fatal Case in Fish Merchant. N. W. Elton, Buffalo.—p. 219.

Serum Phosphatase in Differential Diagnosis of Obstructive Jaundice. A. S. Giordano, Agatha Wilhelm and Mildred C. Prestrud, South Bend, Ind.—p. 226.

Torula Meningitis in Child. R. D'Aunoy and C. R. Lafferty, New Orleans.—p. 236.

General Hospital Laboratory Costs. W. P. Stowe, San Francisco.—p. 239.

Laughlen Test for Syphilis.—Beck states that the Laughlen test for syphilis is less time consuming than other flocculation tests and the results are easier to read (not interpret). It is of value in following the response of serums of patients under treatment, for testing donors for emergency transfusions and for preoperative cases. The test requires as much experience and skill in its performance and interpretation as other flocculation tests and should be performed under the supervision of an experienced serologist. In comparing the Laughlen test with 1,000 Kline tests, 1,100 Kolmer-Wassermann tests and 100 Kahn tests, the Laughlen test was shown to be just as specific and a little more sensitive than the other tests. The test is suitable as a routine test; the positive and doubtful results should be checked by another reliable test. The Laughlen test has not yet been shown applicable to the testing of spinal fluids.

Flocculation Test for Syphilis.—Mazzini describes a modification of the slide flocculation test for syphilis, in which a beef heart and egg yolk extract are used. The use of lipoids from egg yolk, although weakly antigenic by themselves, permit the employment of minimal quantities of beef heart lipoids without endangering the specificity of the results. The hydrogen ion concentration of the suspension plays an important part in the sensitivity of the test, for just as maximal sensitivity of the antigen is obtained at a certain concentration of lipoids, so maximal flocculation is obtained at a definite p_H and salt concentration. The antigen suspension can readily be adjusted to different degrees of sensitivity and is easily controlled. Fluctuation in the sensitivity of every new lot of antigen is eliminated by means of titration. Daily fluctuation in the sensitivity of the antigen suspension is largely eliminated by the use of a buffered saline solution having a constant p_H (from 6.3 to 6.4). The test requires a small amount (0.05 cc.) of serum.

Spirochetal Jaundice.—Elton cites the eighth fatality from Weil's disease reported in the United States. The case is a proved instance of the disease occurring in the Great Lakes port of Buffalo. The disease ran its course in ten days and was recognized clinically by its sudden onset with chills, anuria, generalized muscular pains (especially of the abdominal wall), jaundice, fever, prostration, vomiting, cough and hemorrhagic manifestations. The hepatorenal syndrome was established by marked azotemia and ascending jaundice of great intensity, by the typical death of a guinea pig thirteen days after subcutaneous inoculation in the groin with urine obtained from the patient on the sixth day of illness and the typical death of a second guinea pig ten days after inoculation with the urine of the first guinea pig, obtained at necropsy on that animal. Levaditi stains demonstrated classic spirochetes in enormous numbers in the livers of both animals, as well as in the kidneys.

Decompression of Small Bowel in Intestinal Obstruction. R. J. Noer and C. G. Johnston, Detroit.—p. 46.

Relation of Sex Hormones to Peptic Ulcer.—Sandweiss and his collaborators found that pregnancy has a beneficial effect on the symptoms of peptic ulcer. Records of 70,310 consecutive hospital admissions during pregnancy showed only one case of ulcer. A high incidence (46 per cent) of endocrinopathies (pituitary-gonad-thyroid mechanism) was found in thirty women with ulcer. The symptoms of peptic ulcer are aggravated during the menopause. Thirty of forty Mann-Williamson dogs injected daily with gonadotropic substance were benefited. Eighteen patients with active symptoms of proved peptic ulcer were treated with daily injections of from 2 to 5 cc. of the gonadotropic substance for fourteen consecutive days. Though 78 per cent of the patients were benefited, it is the authors' impression that in the dosage used the substance produced no greater beneficial effect than other parenteral products. Daily subcutaneous doses of from 2 to 5 cc. of the substance had no effect on the free and total acid secretion either in the human being or in the dog. Preliminary observations on twenty Mann-Williamson dogs indicate that urine from normal individuals contains a "protective factor" against Mann-Williamson ulcers and that this "protective factor" is definitely absent from the urine of patients having peptic ulcer.

Pectin for Peptic Ulcers.—Winters and his co-workers treated four dogs with cinchophen and nine with cinchophen and pectin. Those treated only with cinchophen showed a 100 per cent incidence of ulcer, while those given both the cinchophen and pectin showed an incidence of only 11.1 per cent. In general all animals receiving the pectin were in excellent condition while the other four showed intermittent bloody diarrhea, anorexia and nausea. Two control dogs, definitely proved

by operation to have ulcers, were treated postoperatively with cinchophen and pectin. On the twenty-first and twenty-fifth postoperative days, postmortem examination of these dogs showed well healed ulcers.

Preserved Blood and Immunologic Aspects.—Kolmer states that, while sodium citrate is slightly anticomplementary, the complement of citrated (0.35 per cent) human blood kept at from 4 to 6 C. was well preserved up to twenty-one days. The same has been found true of undiluted citrated guinea pig complement kept at from 2 to 4 C. The bactericidal activity of normal citrated human blood for Staphylococcus aureus, beta hemolytic streptococcus and Bacillus coli decreased after from seven to twenty-one days of preservation. The phagocytic activity of the neutrophils of preserved citrated human blood was definitely reduced for Staphylococcus aureus, beta hemolytic streptococcus and Bacillus coli within seventy-two hours after collection of blood, becoming markedly so on or about the fifth day, followed by almost total absence of phagocytic activity on and after the seventh day of preservation. This may have been due to the deterioration of normal opsonins but was mostly due to autolytic and degenerative changes in the leukocytes. The erythrocytes of preserved citrated human blood showed evidences of swelling and dehemoglobinization as early as forty-eight hours after collection with progressive degenerative changes up to fourteen days, when at least 30 per cent were shadows, swollen and fragile. The neutrophils of preserved citrated human blood showed evidences of disintegration with reduction in numbers as early as twenty-four hours after collection, with progressive disintegrative and autolytic changes. The platelets of preserved citrated human blood showed distinct clumping immediately, and there was evidence of deterioration twenty-four hours after collection. They became scarce at the end of forty-eight hours, and only blue chromatin masses remained after five days. The author believes that citrated human blood preserved at from 4 to 6 C. may be useful in the treatment of acute hemorrhage and shock for the purpose of restoration of volume but is inadvisable for the treatment of the anemias, the blood dyscrasias or infections and certainly should not be employed for these purposes after it has been preserved from two to three days.

Nondiabetic Glycosuria.—Of 2,065 patients that Marble and his colleagues saw from 1900 to 1935 who at first observation were thought to have nondiabetic glycosuria they traced all but 1.5 per cent as of May 1, 1937. The condition of the patients was ascertained at the time of tracing. After certain exclusions 1,946 remained on whom this study was based, of which 1,142 are men and 804 women. Of these 1,636 were living and 310 had died. In 193 cases (9.9 per cent of the total) true diabetes has developed. In most instances the diabetes was mild. Factors favoring diabetes were, in approximately the order named, advancing age, overweight, high blood sugar values and in the younger patients a family history of diabetes. The percentage becoming diabetic rose with increasing duration since the initial observation. It was higher in Jewish than in gentile patients. Among the 310 fatal cases 262 deaths were of patients whose glycosuria remained benign, but a significant proportion of these deaths occurred within a year of the first visit. Both among those becoming diabetic and among those remaining nondiabetic the incidence of deaths from cardiovascular and renal diseases was particularly high. The incidence of cancer as a cause of death was five times as high in the nondiabetic as in the diabetic group. There was no death from diabetic coma. Glycosuria, apart from diabetes, may be an accompaniment and a warning sign of degenerative disease and thus be of unfavorable diagnostic import. In the absence of complications, nondiabetic glycosuria seems to exert little or no adverse influence on the life span.

Basal Metabolism and Toxemias of Pregnancy.—Colvin and Bartholomew state that for a long time in the antepartum clinic and lying-in ward of the colored division of Grady Memorial Hospital it has been a recognized fact that an unusually high percentage of the cases of toxemia of pregnancy occur among primigravidas not more than 18 years of age. Bearing this fact in mind, it seemed to them that the hidden factors in toxemia are more concerned with the age of the patient than with the question of parity and that if the primigravida is more prone to develop toxemia it is due to the fact that she is usually young rather than that she is carrying her first child. Therefore they made a study of sixty-two Negro adolescent primigravidas, twenty-four of whom became toxic; that is, nine showed mild to moderate toxemia, eleven preeclampsia, three eclampsia and one abruptio placentae. For the purpose of comparison, 100 consecutive primigravidas from 25 to 30 years of age, from the authors' private cases, were studied. Toxemia developed in twenty-one. There were no cases of eclampsia or abruptio placentae in this group. It was found that adolescent gravidas with basal metabolic rates of plus 10 or more show little or no elevation of blood cholesterol and apparently are not so liable to toxemia and those with basal metabolic rates below plus 10 show hypercholesteremia and are increasingly subject to toxemia as the basal metabolic rate decreases. The high incidence of toxemia of pregnancy in patients whose basal metabolic rates are within a range commonly accepted as normal and who show only moderate hyper-

cholesteremia emphasizes the importance of the trauma of fetal movements as the probable predisposing cause of cholesterol vascular change and the exciting cause of thrombosis in the placental arteries. During the course of developing toxemia there occurs a sharp rise in the basal metabolic rate, associated with a drop in the blood cholesterol. During the puerperium of toxic patients the basal metabolic rate falls to or below its former low level and the whole blood cholesterol rises to or above its former high level. Spasms and constrictions of the retinal vessels are consistently found in all cases of severe toxemia and parallel the severity of toxemia and rise in blood pressure. The high content of arginine in placental tissue is the probable source of hyperguanidinemia in toxemia of pregnancy, through autolysis of acute placental infarcts. Hyperguanidinemia is the probable explanation of vascular spasms and the clinical and pathologic evidences of toxemia of pregnancy. The possibility of preventing cholesterol vascular change in the placental arteries by adequate doses of thyroid extract during pregnancy and the restriction of cholesterol-containing foods seems to be the most effective way of preventing toxemia of pregnancy.

Failure of Ovulation.—Novak calls attention to the fact that failure of ovulation occurs in ostensibly normal women and that it is the responsible factor in some cases of sterility and is the most frequent cause of functional bleeding. There is after all much analogy between the two sexes. Complete aspermia is not at all infrequent in men who otherwise seem quite normal, in whom there is no history of gonorrhea, mumps or other infections and in whom the genito-urinary specialist finds no evidence of infection of the prostate or seminal vesicles. The author states that the same statement can be made as to necrospermia, which likewise is a frequent observation. That anovulatory cases and cases of defective ova which lead to early and perhaps repeated abortion are of endocrine causation, probably of pituitary source, seems certain. It is important to recognize these abnormalities of ovulation, even though further developments must be waited for before they can be treated with any hope of consistent success. Functional bleeding likewise implies a primarily pituitary dysfunction. A promising field of investigation in the effort to find a means of promoting ovulation in nonovulating women is the study of the effects on the ovaries of ovulating and nonovulating women of the gonadotropic principles found in the blood serum of pregnant mares.

Fetal Abnormalities and Placenta Praevia.—Greenhill shows that fetal monsters and deformities occur more frequently in cases of placenta praevia than otherwise. Evidence is presented showing the great part played by environment in the etiology of monsters. Clinical data to support this are obtained from the high incidence of malformed embryos and twins in cases of tubal pregnancy in which the decidual reaction is only slightly developed. The decidual reaction in the isthmus of the uterus is poorly developed and this plays a part in the causation of abnormal fetuses in cases of placenta praevia. The incidence of fetal monsters and deformities for 4,446 cases of placenta praevia (representing approximately 4 million obstetric cases) was 2.5 per cent as contrasted with 0.94 per cent for all obstetric cases. In approximately half of the abnormal fetuses associated with placenta praevia the deformity consisted of defects which can easily be recognized roentgenologically. Therefore roentgenograms should be taken in every case of placenta praevia. The detection of fetal monsters will usually lead to conservative treatment, although cesarean section will have to be employed in some cases in spite of the fetal abnormality.

Ureteral Pain and Menstruation.—Sears cites the records of fourteen patients whose chief complaint was painful menstruation. The pain differed from that of typical dysmenorrhea in that it occurred in the side and radiated along the course of the ureter. Dilation of the ureter of eleven patients resulted in relief, indicating that the pain did originate in that organ. In three women the symptoms, although seemingly related to the ureter, failed to be influenced by dilation. One of these was partially benefited by denervation. This patient also presented some evidence that allergy may play a part in her distress. One patient has obtained at least temporary relief from presacral neurectomy.

Inhibition of Blood Clotting.—Brinkhous and his colleagues show that the inhibition of thrombin formation by heparin requires the presence of a plasma factor not previously recognized. This factor alone is not effective as an "antiprothrombin," and heparin alone appears to have absolutely no effect in this regard. The two in conjunction, however, are highly effective in preventing the formation of thrombin. The new factor has not been identified, and the authors state that it is abundantly present in plasma and in serum. It is apparently not diffusible, for it is to be found in serum which has been dialyzed against physiologic solution of sodium chloride.

Endemic Typhus in Texas.—Kemp points out that endemic typhus in Texas shows few differences from the same disease in other Southern states. It is characterized by its duration of fourteen days, its freedom from complications and sequelae and its low mortality rate. It appears to spare infancy, childhood and old age. The majority of the cases occur among workers of the middle class, particularly in males. It appears to be concerned with occupation in that a great majority of the cases occur in persons employed in shops, grocery stores, grain depots and warehouses in which rat infestation is quite high. At the

same time a considerable number of cases occur among members of the lower social strata whose homes and places of employment show the same degree of rat infestation. Endemic typhus in Texas seems to be almost identical with the clinical manifestations of tropical (Malayan) typhus. At the same time certain distinctions obtain: difference in vector and failure of the serum in Texas cases to agglutinate the anindologenic strain of Proteus. In addition to this the disease in the American Southwest appears to show certain definite clinical and epidemiologic differences from Brill's disease, however similar the two are immunologically.

Tuberculous Lesions in Industrial Workers.—Cummings and his associates state that the Field Division of the Saranac Laboratory has determined the incidence of tuberculous lesions recognizable in good stereoscopic roentgenograms of the chests of large groups of workmen engaged in several industries located in various parts of the United States. A preliminary analysis of these groups disclosed that, of 4,012 white male workmen in whose roentgenograms evidence of an occupational exposure to dust could not be found, 4.76 per cent had tuberculous lesions. The x-ray observations of 5,000 steel mill workers were analyzed and compared with 5,000 male miners. The crude incidence rate of 5.24 per cent of the steel mill workers compared favorably with that for "normals." The incidence of tuberculous lesions increases with age, rising among steel mill workers from about 1 per cent in those less than 20 years of age to 12.5 per cent for those from 65 to 74 years of age. The rise in incidence with age is due to the development of new infections at all ages rather than to the survival of groups whose incidence was considerably higher in former years. The ratio of the incidence of tuberculous lesions to mortality from pulmonary tuberculosis has been found fairly constant at most age groups for white male steel mill workers. This ratio indicates that one death occurs for each eighty cases with recognizable lesions. Among miners the incidence of tuberculous lesions has been shown to increase as the degree of reaction to dust progresses. Age has exerted an influence on the incidence of lesions in presilicotic miners but its effect has been overshadowed in the presence of true silicosis when the incidence rates have risen to astonishing levels. Tuberculosis with silicosis is an occupational disease in seven out of eight miners less than 35 years of age but in only half of the miners more than 65 years of age.

Blastomycosis.—Martin and Smith report thirteen cases of American blastomycosis (Gilchrist's disease). Cases 1, 2 and 3 illustrate the clinical picture of the terminal stages of systemic blastomycosis in which no type of therapy is effective. Cases 4, 5 and 6 show the rapid spread of the disease during treatment with iodides. Patient 4 had a chronic pulmonary infection, presumably blastomycotic, for five years before admission. He improved slightly during the first three weeks in the hospital, but, after the diagnosis of blastomycosis was established and iodide therapy was instituted, the disease spread rapidly and the patient died within four weeks. In case 5 the administration of iodides did not prevent the development of subcutaneous abscesses. In case 6 new foci in the lungs and additional lesions in the bones developed while iodides were being administered. Cases 7, 8 and 9 illustrate the manifestations in patients who, when first seen, were in good physical condition and should have responded to therapy. Patient 7, although infected for six years, had not become hypersensitive to the fungus and no antibodies developed. Patient 8 improved rapidly with iodide therapy in the hospital and continued to improve for six months after discharge, at which time he was apparently well and iodide therapy was discontinued. After remaining in good health for a year, the patient had a relapse and died. Patient 9 was inadequately treated with iodides and, although he had a slowly progressive disease for four years, he did not become hypersensitive and no antibodies developed. Patients 10, 11 and 12 improved satisfactorily with the combination of iodide and vaccine therapy. Patient 10 is of special interest in that she is the only surviving patient who had a high titer of serum antibodies. She was moderately allergic and, after desensitization by vaccine treatment, responded well to iodides. She is in good health four years after the onset. A high degree of allergy without serum antibodies existed in case 11. Injection of desensitizing doses of vaccine followed by iodide therapy resulted in rapid healing of the lesions. The failure to develop serum antibodies after vaccine therapy is offered as evidence that the beneficial effect of the vaccine did not result from active immunization. The harmful effect of iodides on the cutaneous lesions of a markedly allergic patient are shown by case 12. Fever, loss of weight and extensive spread of the lesions occurred after iodide administration and improvement resulted only after the iodides were stopped and vaccine therapy was instituted. Partial desensitization was accomplished in case 13 by the intravenous injection of the carbohydrate fractions of the fungus.

Morbidity Following Cholecystectomy.—In a follow-up study of 264 cases from one to four years after cholecystectomy for cholecystitis, Eliason and North found that only 6 per cent (sixteen) were not relieved of the symptoms for which operation was designed. In four relief was delayed, and in others extraneous factors developed after operation which were attributed, incorrectly by the patient, to the gallbladder. The 6 per cent who continued with many of the same symptoms after removal of their gallbladders fall into two equal groups. In eight, no gross evidence of gallbladder disease was evident at

the time of operation, and cholecystectomy could not be expected to give relief. In the other eight the surgeon found a diseased gallbladder, and usually gallstones, yet the patient was not helped by cholecystectomy. In the latter group the chief source of the patient's complaints was extrabiliary and the finding of a biliary lesion was purely incidental. A certain number of these diagnostic errors were inevitable, despite thorough preoperative study of the cases. In others the errors might have been avoided by attaching due significance to symptoms which were regarded simply as atypical, by more careful attention to the patients' own description of their symptoms, and by a recognition of the fact that, even when gallstones are actually present, it may not be fair to attribute all the patients' digestive symptoms to them, since many gallstones are "silent" ones.

Prothrombin Deficiency and Vitamin K.—Stewart used vitamin K in the treatment of twelve patients suffering from obstructive jaundice and varying degrees of liver damage and one with a postoperative external biliary fistula. The amount of vitamin K-cholic acid mixture taken varied from 0.8 to 24.8 Gm. and the duration of treatment from one and a half to fourteen weeks. The average increase in plasma prothrombin under vitamin K therapy was 32.8 per cent. The frequency with which plasma prothrombin is reduced in obstructive jaundice is striking. The author states that during the course of this study only one case has been seen in which obstruction to bile flow for more than a week has not been associated with plasma prothrombin levels of less than 84 per cent. This patient's appetite had remained remarkably good and the biliary obstruction was incomplete. In the preoperative group the response to vitamin K-cholic acid has been invariable. It seems to be true, however, that the more severe the liver damage the less marked is the prothrombin recovery. Little if any correlation is discernible between the degree of depression of plasma prothrombin and the plasma bilirubin level. This is not surprising, since the excretory function of the liver is only one of the factors concerned in the maintenance of plasma prothrombin. Also, even when bilirubin is being excreted, bile deficient in cholic acid and hence less effective in promoting absorption of vitamin K may be formed by the damaged liver. A drop of from 20 to 40 per cent in plasma prothrombin concentration immediately after operation is to be expected, dependent perhaps on such factors as blood loss and dilution of plasma, clotting and depression of liver function by anoxemia and anesthesia. The fall is transitory, however, if vitamin K-cholic acid feeding is resumed at once. A safe preoperative plasma prothrombin level, preferably above 75 per cent, is highly desirable. Since the prothrombin level may change quickly, the need for frequent determinations in the early postoperative period is necessary. Blood transfusion is needed to replace lost blood, but vitamin K-cholic acid therapy is indicated in order to prevent further bleeding. The plasma prothrombin level depends on the functional capacity of the liver as well as on absorption of vitamin K from the intestine.

Familial Benign Chronic Pemphigus.—The Haileys describe what they believe to be a heretofore unreported dermatologic entity—familial benign chronic pemphigus. They cite four cases of the condition in brothers involving two families. The individual lesion began as small vesicles, which rapidly became flaccid bullae. Early rupture followed, with formation of an amber-colored crust. The peripheral spread was bullous. Nikolsky's sign was present. Possible etiologic factors, such as occupation, ingestion of drugs, exposure to sunlight, irritation from clothing or from chemicals and the presence of an anatomic anomaly, were definitely eliminated. The condition is familial and recurs over a long period of years. While simple wet dressings are palliative, apparently no treatment influences the course of the disease. It is benign in that no constitutional signs or symptoms accompany it. Varying degrees of itching are present. The eyes of one of the patients were affected by the condition. After the condition of the eyes cleared up, both corneas and conjunctivas were normal, as was the skin in all four patients.

Treatment of Trachoma with Sulfanilamide.—Richards and his co-workers treated twelve Indian children, all showing active trachoma with follicular hypertrophy and pannus, with sulfanilamide. All showed striking improvement, and at the end of four and a half months the conjunctiva in each instance had become follicle free and smooth. Except in one eye, corneal infiltrates disappeared and the corneal activity was apparently checked. Two untreated children used as controls showed no improvement during the period of observation but improved rapidly when sulfanilamide was given later. Sulfanilamide brought about the disappearance of the epithelial cell inclusion bodies characteristic of active trachoma.

Progressive Alcoholic Cirrhosis.—Hall and Morgan present a study of sixty-eight cases, selected from several thousand necropsies as instances of the progressive, or active, type of alcoholic cirrhosis as described by Hall and Ophüls. This condition may be conveniently designated as subacute alcoholic cirrhosis. Fifty-seven of the patients were consumers of alcohol in some form and fifty-one were "heavy drinkers," chronic alcoholic addicts. Only one of the sixty-eight patients denied that he consumed alcohol. This group of patients were, then, quite largely suffering from alcoholism. The livers were mostly of the large (average weight 2,760 Gm.), pale yellow fatty type, with the connective tissue actively proliferating about disintegrating hepatic cells. The picture was that of early or subacute alcoholic cirrhosis. Jaundice was present in 50 per cent of the patients; in twenty-four the icteric index was 50 units or higher. Approximately 50 per cent of the livers contained excessive amounts of fat. The authors believe that in the majority of cases the enlargement and fatty infiltration of the liver con-

stitute the first development and that this passes imperceptibly into the subacute phase of cirrhosis, to be followed later, if the patient survives long enough, by the appearance of the small hobnail liver. A small percentage of the patients die during the subacute stage as a result of complicating infections, dietary deficiency diseases, hepatic insufficiency, portal hypertension, alcoholic psychoses and other disorders. They also believe that the term "alcoholic cirrhosis" has a firm basis in etiology. Much of the confusion regarding this subject has been due to the study of the chronic Laennec type of case, in which cirrhosis due to alcohol cannot be distinguished readily from that due to other causes.

Interpretation of Endometrial Biopsy.—Kotz and Parker studied the menstrual cycles of 500 women, 300 of whom were controlled for a sufficient length of time to obtain accurate data on the menstrual history and adequate biopsy material for study. The types of cases studied included amenorrhea, oligomenorrhea, hypomenorrhea, menorrhagia, metrorrhagia, menopause, sterility and dysmenorrhea. A complete history with emphasis on the character of the menstrual cycles since the onset at puberty was obtained in each case and general and pelvic examinations were done. Laboratory work consisted of blood counts, urinalysis, Kahn reactions, basal metabolism rates and blood tests for the estrogenic and gonadotropic substances. There were no specific endometrial patterns for the menstrual disorders. Amenorrhea may possibly be an exception, since here the endometrium was usually in a stage of follicular arrest or atrophy. When other types occurred, menstruation followed shortly thereafter. Specific changes in cases of the menopause were not demonstrable but the endometrium merely reflected the degree of ovarian failure. In the early menopause an abnormal luteal phase was found; later, with further loss of ovarian function, the follicular and eventually the atrophic phases occurred. Oligomenorrhea and polymenorrhea occurred with practically every type of endometrium. In the cases of scanty and irregular periods 78 per cent showed evidence in the endometrium of some luteal function, although in 38 per cent it was of an abnormal type. In the cases of functional bleeding or polymenorrhea 51 per cent showed complete lack of corpus luteum function while an additional 33 per cent showed abnormal corpus luteum function as evidenced by the endometrial pattern. The occurrence of bleeding from all phases of the endometrial development with varying levels of the ovarian hormones would seem to suggest that a third factor—the bleeding factor—is a necessary activator of this phase of the cycle. In the purely functional type of dysmenorrhea there was usually a relative and often actual preponderance of the action of theelin. Pseudomenstruation, which is often considered to be synonymous with anovulatory menstruation, occurred in forty cases.

Hyperglycemia Without Glycosuria.—Davidson points out the association between hyperglycemia and deviations in a wide variety of metabolic processes and advances the theory that hyperglycemia, by itself, may be one of the determining factors in certain clinical manifestations. Hyperglycemia has not generally been considered as a causative factor responsible for disturbances in metabolism which might be reflected in clinical manifestations. The demonstration of hyperglycemia without glycosuria in a large number of cases (seventeen of which are reported) presenting a wide variety of complaints has given the author an opportunity to observe the effects of treatment designed to correct this deviation in metabolism. Improvement in clinical manifestations associated with therapeutic measures has occasioned the development of a theory that hyperglycemia may act as a determining factor in initiating and maintaining unfavorable metabolic conditions, which in turn are reflected clinically. Clinical improvement occurred when measures designed to correct hyperglycemia, the existence of which has been demonstrated through dextrose tolerance testing, were instituted. The patients, except one, could not be considered typically diabetic in the sense that they exhibited hyperglycemia with glycosuria, as repeated urine examinations failed to reveal sugar in the urine, in some instances over a period of years. The inappropriate concentration of dextrose and not the inappropriate supply of insulin is ascribed as the direct cause of such clinical exhibitions. Such histories as those submitted and experience with several score of other equally striking cases treated in the course of ten years have prompted the author to formulate the theory that hyperglycemia by itself operates at times as a determining influence in the initiation and maintenance of metabolic disturbances which may be described as metabolic processes operating under other than optimal conditions and which in turn are reflected in clinical manifestations.

Proctoscopic Examination. E. B. Williams, Chicago.—p. 374.

Menopause and Painful Stiffening of Shoulder.—Voight describes the painful stiffening of the shoulder that he has observed to occur in women during or at the beginning of the climacterium who were engaged actively as typists, pianists or teachers using the arm a great deal in their demonstrational teaching methods. The characteristic symptom in these cases was a marked pain in the right shoulder—the "used" arm—at first causing discomfort in the abduction of the arm and then leading to progressive limitation of this motion and eventuating, in one case, in complete adduction contracture. In one case of a left handed person the left shoulder was affected. Following the onset of pain and limitation of abduction, there develops as a rule limitation of rotation movements, the motion anteriorly

showing the least interference with movement. During this time palpation and x-ray examination of the shoulder joint reveal no changes. It is evident, therefore, that the seat of the disease and the disturbances in mobility are situated extrascapularly. In the diagnosis of this condition the most important factor is to exclude a humeroscapular arthritis. The author brought his cases to recovery by iontophoresis with histidine salve and massage, with the additional use, in appropriate cases, of the abduction splint. To these methods the author adds injections of large doses of progynon, thus attacking, he believes, the cause of the condition as well as the local involvement. The local methods were extended to the spaces under the deltoid and subscapularis.

Autohemotherapy for Hyperemesis Gravidarum.—Saxon and Stoll advocate autohemotherapy for the relief of hyperemesis gravidarum, based on an allergic concept of the condition. The dosage that they employed ranged from 3 to 10 cc., depending on the severity of the symptoms. The intervals between treatments were chosen according to the effect of the treatment and to the progress of desensitization in each individual. Four cases are reported which show the effect of this method. The authors state that they have used autohemotherapy in about seventy-five cases of hyperemesis and have yet to see a case that did not respond.

Skeletal Metastasis in Cancer.—Geschickter and Maseritz emphasize the incidence of skeletal metastasis in which there is no clinical evidence of a primary lesion and submit data relative to osseous invasion by metastatic carcinoma. Their data are based on a study of 5,739 cases of carcinoma arising from various organs. There were 356 cases in which carcinomas metastasized to bone. The primary source of the metastasis was definitely determined clinically in 296 instances. The first indications of disease in the remaining sixty metastases of unknown origin were symptoms referable to the skeletal system. "Rheumatic pain" was a common complaint, and in several instances the patients were treated for arthritis. In one case a mass was palpated in the neck, which later proved to be a lymph node metastasis; in the other fifty-nine cases there were no subjective or objective signs referable to other systems. The prostate was the most common source of skeletal metastasis, the breast second and the kidney third, while the stomach, lung, thyroid and other organs were involved less frequently and in the order given. The size of the primary lesion is no index of the probability of metastasis. Metastasis to bone may occur many years after the primary operation and in the present series of 2,306 cases of breast cancer skeletal metastasis was observed as late as 18.25 years postoperatively; the average time was 31.3 months. Irradiation of the osseous lesions relieves pain and prolongs the life of the patient.

Gold Therapy for Arthritis.—Key and his associates treated seventy patients with arthritis of the proliferative type with myochrysine (sodium aurothiomalate). The patients were not selected, except that before treatment was started it was agreed that the patient had an active arthritis of the proliferative type, which appeared to be chronic and progressive and of sufficient gravity to warrant the repeated administration of an admittedly dangerous drug. In only three cases had the disease been present less than one year; in the others from one to more than ten years. A control series was not studied, but the previous treatment of fifty-three of these patients with atrophic arthritis was recorded. In spite of various types of previous treatment, the disease had remained active and therefore the authors believe that in such a group of patients controls are not necessary. The preparation was administered by intramuscular injection with a fine needle in the deltoid or gluteal region. In adults the usual initial dose was 0.05 Gm.; one week later 0.1 Gm. was given and this dose was continued for twenty weeks until the patient had received 2 Gm. of myochrysine or 1 Gm. of gold. If a toxic reaction occurred, the treatment was discontinued or the dose was decreased. In children the initial dose was 0.0125 Gm. and this was increased to 0.025 Gm. At the end of the first course of treatment the patient was given a rest period of six weeks; then, if the disease was still active or if the blood sedimentation rate was accelerated, a second course was given; after a second rest period of from four to six months, a third course was given if indicated. Twenty patients received 1 Gm. or less of myochrysine, twelve from 1 to 2 Gm., twenty-six from 2 to 4 Gm. and twelve from 4 to 6 Gm. Of the two cases of proliferative arthritis following rheumatic fever, the disease was apparently arrested in one and considerable improvement occurred in the other during the treatment but treatment was discontinued owing to severe toxic reactions. In the four cases of proliferative arthritis which appeared to be due to the gonococcus, the gold treatment appeared to have little if any beneficial effect and it was not continued. The arthritis was not improved in the two cases of lymphogranuloma, but in one of these the rectal condition showed marked improvement while treatment was being given. In the nine cases of spondylitis ankylopoietica, the gold therapy did not result in sufficient improvement to warrant its continued administration. Its use was discontinued and sulfanilamide was substituted, which appears to have caused definite improvement, though it is still too early to state whether or not it will arrest the disease. Of the fifty-three cases of atrophic arthritis, in two the arthritis was aggravated, in six there was no improvement, in seven there was improvement while under treatment (but the patients did not return for final check-up), in four there was slight improvement, in thirteen moderate improvement occurred, in eighteen the improvement was marked and in three the disease appears to have been arrested. The signs of improvement were disappearance of swelling in ten patients, decrease of swelling in twenty-five, increased movement in twenty-seven, disappearance of pain in twenty-one, diminution of pain in fifteen, decrease in the sedimentation rate in thirty-six of forty-six patients tested and increase in physical activity of thirty-seven of the forty-seven patients checked for this factor. Twenty-two patients resumed their house work, four of the seven children returned to school, six resumed their occupations and five merely stated that they were able to do more than they could before this treatment. Thirty-six of the forty-three underweight patients gained weight while under treatment. There also was a marked improvement in the morale of most of the patients, even in many who had toxic reactions.

Vitamin C in Poliomyelitis.—From his experiments on monkeys, Sabin found that both natural and synthetic preparations of vitamin C had no effect on the course of experimental poliomyelitis induced by the nasal instillation of the virus. Immediately after the virus was instilled the administration of vitamin C was begun, and if the vitamin were capable of exerting any effect on the virus or the tissues it could have done so even before the virus had begun to multiply. Monkeys whose store of vitamin C was depleted reacted in the same way as those receiving an adequate diet. The author finds no apparent explanation for the difference between his results and those reported previously by Jungeblut. During the present investigation, monkeys on a scorbutic diet died of spontaneous acute infections, chiefly pneumonia and enterocolitis, while their mates receiving an adequate diet remained well. Osseous and other changes of human scurvy developed in the monkeys that survived the scorbutic diet, and the vitamin C used in this study produced healing and calcification in the bones as well as it checked the edema and hemorrhagic diathesis.

Acute Diffuse Bronchiolitis.—McKinlay reports a case of acute diffuse bronchiolitis in a woman of 20 in whom the main physical sign was the presence of medium and somewhat fine moist rales over considerable portions of both pulmonary fields, which later became quite universal. In the absence of signs of frank consolidation and appreciable alteration in breath sounds, the impression gained was that of acute diffuse bronchiolitis as distinguished from bronchitis or bronchopneumonia. Later roentgen examination showed the development of contiguous areas of bronchopneumonia and simulated the signs of miliary tuberculosis. The course of the disease was characterized by mild respiratory symptoms and slight fever of nine days followed by a febrile period of nineteen days. The temperature was moderate and fell by lysis. While of rare occurrence in young adults during recent years, reports of similar cases indicate that bronchiolitis with similar features is not uncommon in infants and the aged, and during epidemics it is also often seen in adults. The entity suggests a specific etiologic agent (Haemophilus influenzae).

The Water Soluble Vitamins. A. P. Meiklejohn, Boston.—p. 518.

Citrates in Treatment of Rickets.—Shohl and Butler used citrate mixtures in the treatment of two cases of infantile rickets. The amount of citrate given each patient daily corresponded approximately to that contained in five or six large oranges. X-ray studies showed that healing had taken place during the administration of citrates, without vitamin D therapy. The deposition of lime salts was first detected in these patients on the ninth and fourteenth days of therapy, respectively. Not only the early date of deposition but the amount of deposition compared favorably with that obtained with cod liver oil. Both patients gained in weight during the periods in which the rickets was healing. The serum analyses in both patients showed a lowering of the total calcium and a rise in the phosphate, and subsequently in case 1 a rise in both. In this respect the children reacted similarly to rats. Tetany was never manifest by either a positive Chvostek's sign or convulsions. Latent tetany was absent. This new form of therapy not only offers an adjunct to accepted measures for the treatment of infantile rickets but also may have application to other types of disorders of calcium and phosphorus metabolism.

*Death in Newborn and Stillborn Infants. J. S. P. Beck, Worcester, Mass.—p. 558.
Children's Surgery. W. E. Ladd, Boston.—p. 564.

Death in Newborn and Stillborn Infants.—In twenty-five deaths of infants varying in gestation age from five to nine months and in which postmortem material and clinical data were available, Beck observed that the cause of death in 64 per cent was traceable to intra-uterine disturbances other than those related to the fetus or to difficult delivery. The remaining 36 per cent consisted of congenital malformations incompatible with extra-uterine life (12 per cent), injuries due to difficult labor (20 per cent) and syphilis (4 per cent). The close relation between death and the complications of pregnancy or labor or both, the author states, is in complete harmony with a recently reported (Bundesen and his associates) relation involving many hundreds of similar cases. All ailing prospective mothers should be brought as near to normal health as possible before delivery is allowed to start if the welfare of the infant is the more important. The blood in anemia should be brought to normal range, in acidosis or alkalosis the carbon dioxide combining power of the blood should be adjusted to normal, in nutritional edema the blood proteins should be raised, and the toxemias of pregnancy should be treated with great care. Mothers having a history of abortions, miscarriages, stillbirths or premature births should be given vitamins and suitable endocrine therapy in the antepartum period to carry the pregnancy to term. Narcotics and anesthetics seem contraindicated in mothers whose health is below par. Infants of such mothers will do badly

immediately following birth and the armamentarium for immediate and effective removal of foreign materials from the respiratory passages should be ready for use. Effective means for resuscitation should be made available for immediate use during the critical period just after the cord is severed. It seems logical to cleanse the nose and throat before the cord is cut and to use resuscitation measures afterward.

Endamoeba Histolytica Infestation in Philadelphia.—In a stool survey of 1,060 freshmen in a college in Philadelphia, Arnett found that 4.1 per cent were positive for Endamoeba histolytica. A study of this group in relation to their home residence indicated a significantly higher percentage of positives (5.1 per cent) in students from Philadelphia within fifteen miles of City Hall than in those who came from New Jersey within fifteen miles of Philadelphia's City Hall (0.9 per cent). The health records of the positive cases indicated that, as regards gastrointestinal symptoms or other evidence of disease, they were not inferior to a group of the same size in which no intestinal parasites were found. A survey among a small group of inmates and employees of an institution for the aged in Philadelphia indicated an incidence of 11.3 per cent of stools positive for Endamoeba histolytica. A study of 293 stool specimens from food handlers in a Philadelphia institution showed a positive incidence of 6.5 per cent. When divided into those previously examined and those examined for the first time, the incidence among the former was 1.6 and among the latter 10.3 per cent. This difference appears to be due to the fact that the previously positive persons were successfully treated, so that in subsequent yearly examinations they appear negative. Treatment consisted of the oral administration of iodochlorhydroxy-quinoline, chiniofon and *p*-carbamido-phenylarsonic acid. Satisfactory results were secured from these three drugs without failures and without serious reactions. In no case has recurrence been noted. The author states that his data confirm Craig's estimate that between 5 and 10 per cent of the population of the country harbor Endamoeba histolytica in the intestinal tract but do not confirm the belief that symptoms are commonly encountered in these carriers.

Peptic Ulcer.—Miller states that peptic ulcer can no longer be regarded clinically as merely a local disease of the stomach or duodenum. The internist must concern himself with the person's heredity, with his physical, mental and emotional makeup, with the nature of his endocrine and his autonomic nervous equipment, with his environment and social status and with his personal habits of life. Whether or not the etiology of ulcer is proved eventually to depend on conditions outside the stomach or duodenum itself, such an established clinical association is of diagnostic importance and it seems to have a bearing on treatment. As important as the physical constitutional characteristics of the subject of ulcer is his psychic personality. He usually is of a nervous temperament, worries unduly and is introspective. He is nervous in the sense of being fearful, highly sensitive, intense and strenuous. There is also some experimental work tending to show a relationship of peptic ulcer to glandular dysfunction. Peptic ulcer, furthermore, frequently develops in predisposed people when they are subjected to unusual emotional strain, continued worry and anxiety. The use of tobacco or alcohol is believed by many to be of etiologic significance, and either may be the precipitating factor in a person predisposed constitutionally to ulcer. Other personal habits which involve overwork, loss of sleep and nervous exhaustion probably act in the same fashion and deserve special attention in prevention and treatment. Sex and age traditionally are of importance, but ulcer may occur at any age. An excess of free hydrochloric acid is commonly regarded as of etiologic and diagnostic value, and certainly its association is frequent, at least in duodenal ulcer. It is present in many normal persons, however, and presumably characterizes a certain constitutional type. Neutralization of the free hydrochloric acid is most important to cure, a clinical fact which in itself indicates an etiologic relationship. These various clinical aspects of ulcer are of etiologic as well as of diagnostic value, though the crucial considerations from the diagnostic angle are, of course, the history and x-ray observations.

*Renal Dwarfism. R. M. Bates.—p. 34.

Renal Dwarfism.—Bates describes a case of an adult mentally defective dwarf who during life, and at the postmortem examination, was thought to have renal rickets. Histologic examination of one femur showed no rachitic change and the parathyroids were normal. The high blood pressure and retinitis pointed to chronic nephritis, but this presumably followed a renal and ureteral dilatation, which also occurs in the nonhypertensive variety of renal dwarfism. While a small ureteral stone may have played a part in the production of dilatation on the right side, the enormous dilatation on the left side appeared to be secondary to a congenital stenosis of the ureteral orifice. The author suggests that a more exact nomenclature be used in which dwarfism with rickets be called "renal rickets" and dwarfism without rickets "renal dwarfism." Renal infantilism would be reserved for cases in which true infantilism is associated with renal dwarfism. Such cases might or might not show rickets. The three conditions are probably parts of one large whole. It may be that renal damage in infancy causes the circulation of chemical substances in the blood stream influencing, to a greater or lesser degree, general growth (pituitary), growth of the long bones (parathyroids) and sexual development (gonads direct or through the pituitary).

Etiology of Glaucoma.—Weinstein studied the possible relation of glaucoma to blood pressure. The study showed that the systolic blood pressure of 100 sound persons ranged from 120 to 200 mm. of mercury and the diastolic from 60 to 95 mm., while the corresponding values in 150 persons suffering from glaucoma were 120 to 230 mm. and 60 to 115 mm. respectively. The difference is not sufficient to suggest the existence of hypertonia in glaucomatous persons. Attention was next directed to the small vessels, but no values that are characteristic of the tension of glaucoma could be determined either within the large vessels or within the precapillaries. It was found however that, when the ocular tension increases, the pressure within the intra-ocular vessels increases also but that that of the extrabulbar vessels does not. Müller and Parrisius discovered by capillaroscopy that the vasomotor instability of glaucomatous persons was a characteristic peculiarity. Mészáros, Tóth and the author came to the same conclusion. The reactive hyperemia (the filling up of the bloodless finger with blood, normally within one to two seconds) is prolonged in glaucomatous persons. These data seem to prove that the capillary pressure increases in glaucomatous persons. During investigations by means of the tonograph the author observed that there is a difference between the amplitude of the oscillations in glaucomatous hypertonic persons and that in sufferers from thrombosis of the central retinal vein. The tonographic reading in glaucomatous persons at 200 mm. of mercury pressure shows a normal oscillation of from 8 to 10 mm., against over 15 mm. in thrombotic individuals, proving that there is a decrease of elasticity in the walls of the vessels. Inflammatory glaucoma rarely occurs in persons suffering from grave arteriosclerosis (nephrosclerosis and diabetes) but their capilloscopic reading, as well as the tonogram and the dermal-tension value, differs from that found in cases of glaucoma. The acute capillary dilatation observed during glaucomatous attacks is possible only with an elastic wall of the vessels and not in the rigid brittle wall of arteriosclerotic persons. Of the 3,254 glaucomatous patients reviewed from the First Ophthalmological Clinic from 1904 to 1933—and of the smaller series from the ophthalmologic department of the policlinic—60 per cent were women, and 80 per cent of the acute attacks befell women at the time of the climacteric. This ratio explains the relation of glaucoma to the endocrine system and renders the vasomotor instability of glaucomatous persons easily understood, as during the climacteric women are disposed to congestion, perspiration and similar vasomotor reactions. The frequency of glaucomatous attacks in winter is conspicuous. This connection with meteorologic conditions again points toward vasomotor instability of the capillaries. Primary glaucoma, in contrast to the inflammatory type, develops because of arteriosclerotic alteration and accordingly does not show any great increase in ocular tension. The destruction of the optic nerve seems to be the sequel to the circulatory defect and to the resulting alimentary deficiency. The third type of glaucoma is that following thrombosis of the central retinal vein. As a rule the victims are people of advanced age whose blood pressure is high and the amplitude of whose tonographic reading is large. In whatever organ thrombosis may be located, pathologic products such as carbonic acid, lactic acid, citric acid and hydrochloric acid accumulate, and this must necessarily be the case within the eye. It is probable that under the influence of these substances the vitreous body slowly begins to swell up and gradually increases the ocular tension, and glaucoma in these cases of thrombosis of the central retinal vein is probably caused by an alteration in the hydrogen ion concentration.

Recent Theories of the Nature of Glaucoma. I. C. Michaelson.—p. 105.
*Carcinoma of Pancreas. Marjorie Gillespie.—p. 118.

Carcinoma of Pancreas.—According to Gillespie, in a total of 1,861 postmortem examinations performed during the last seven years forty-three pancreatic tumors were found, 2.3 per cent, or about 10 per cent of all tumors. Thirty-one of these cases occurred in men and twelve in women. Their ages varied from 36 to 79 years, the mean being 60 years. In thirty-two cases the neoplasm originated in the head, in five in the body and in six in the tail of the pancreas. In only fifteen of the tumors of the head of the pancreas was jaundice present. Jaundice is an aid to diagnosis, but no jaundice was evident in more than half of these cases. Metastases to various parts of the body were found in thirty-three instances. Metastases were more common in carcinomas of the parenchyma than in those of

the duct. Microscopic sections were available in only thirty-one cases. Of these, eleven were duct carcinomas and twenty were carcinomas of the parenchyma. Of the former, ten originated in the head and one in the tail; of the latter, ten were tumors of the head, six of the body and four of the tail. The duct carcinomas showed infiltration of other organs by direct extension in six out of the eleven cases. The organs affected were the liver, the duodenum and the left adrenal. All the parenchymatous carcinomas showed wide metastases, the adrenals being the most commonly affected organs. The duct carcinomas tended to be scirrhous in type, the neoplastic ducts being surrounded by masses of fibrous tissue. The parenchymatous tumors consisted of masses of cells varying in shape—oval, cuboidal or round.

Histologic Changes in the Brain in Mongolism.—Meyer and Jones examined histologically the brains of fifteen cases of mongolism and in ten of these they found definite changes. These changes consisted mostly of widespread proliferation of the fibrous glia, which often was not accompanied by corresponding changes in the myelin and cell picture. The pathogenesis of the changes is discussed, and it is shown that the observations are not likely to represent the pathologic substrate underlying mongolism. They throw light, however, on the interpretation of the changes reported by previous writers. Most of these investigators discussed the changes in the brain as an expression of the pathologic process underlying mongolism. Reserve is necessary in submitting far-reaching conclusions. The authors' material, which represents a wide variation in length of life, shows that relatively recent changes may be found even in persons who die in the third decade of life. It is therefore likely that all such changes must be regarded as accidental to the pathologic changes of mongolism. It may well be that the incidence of pathologic changes is greater in mongolism than in other conditions, owing to the peculiar constitution of the mongol. One might even assume that the same functional abnormality underlying mongolism produces also the histologic changes which, though constant, would obtain a certain significance as indicator of the pathogenesis of mongolism; but this is at present purely speculative. Enough is not known about the reaction of the brain to bodily diseases, especially in infancy and childhood, and therefore it cannot be decided whether this reaction is more severe in mongols than in other defective and normal persons. Systematic control will be necessary before a real appreciation of the cerebral changes in mongols will be possible. Investigations in this direction are in progress in this laboratory. There is no consistent correlation between the size of the brain stem and the degree of glial scarring, though it is conceivable that the glial scarring, if severe, might contribute to the smallness of size. Mongols are considered to be "able bodied" and gross neurologic symptoms are absent. The authors' investigation has demonstrated to them how erroneous comparative work based on measurements of cyto-architectonics and myelo-architectonics alone might be. Such comparative studies are necessary, but they must include a complete histologic analysis if serious errors are to be avoided.

Wernicke's Encephalopathy.—Campbell and Biggart cite twelve cases of Wernicke's encephalopathy, in only one of which frank chronic alcoholism could be established; in the others alcohol could be completely eliminated as a causal factor. The nonalcoholic cases occurred as complications of a wide range of primary conditions: gastric carcinoma (three cases), chronic dyspepsia with gallstones and old gastro-enterostomy, pernicious anemia, macrocytic anemia following intestinal resection, pregnancy (two cases; hyperemesis was present in one case), bronchiectasis, chronic pyosalpinx and a vague illness in a child, possibly whooping cough. The pathogenesis of the encephalopathy is not clear. However, of the pathogenic factors which may be present singly or in combination, vitamin deficiency, especially deficiency of vitamin B_1, seems to be the most obvious possible common factor in the range of primary diseases which lead to the encephalopathy. Wernicke's encephalopathy is a clearcut pathologic entity which, unless specifically looked for, may easily be missed at postmortem examination.

Experimental Diabetes Insipidus.—In an attempt to arrive at some conclusion as to the factor or factors responsible for the production of diabetes insipidus, experiments were begun by Biggart and Alexander some three years ago on the dog. They found it possible to produce diabetes insipidus in the dog (temporary polyuria in fifteen and permanent in fourteen) by a lesion which involves the supra-optic nuclei or the supra-optic hypophysial tracts. It appears that the hypothalamus and the posterior hypophysis complex must be considered a functional unit as regards water metabolism; the experiments suggest that the supra-optic hypophysial tract serves as the motor-secretory mechanism for the elaboration of the antidiuretic factor. In other words, even when the lesion found in a patient with diabetes insipidus is confined to the hypothalamus, the syndrome is in effect an endocrine deficiency due to the lack of stimulus for the secretion of the hormone. It is probable that there exists some quantitative relationship between the amount of damage done to the supra-optic hypophysial tracts and the presence of the polyuria, as in the present experiments unilateral damage never resulted in permanent polyuria. The three phases which were seen during the onset of the permanent experimental polyuria were a transient polyuria, a period of normal output and finally the appearance of the permanent phase. Hypophysectomy or pancreatectomy abolished this polyuria, while thyroid medication usually increased it. The authors conclude that the supra-optic nuclei are in some way sensitive to the water needs of the body, that they serve as the nervous centers which stimulate the secretion of the antidiuretic factor and that

this factor is in all probability manufactured in the pars nervosa. Diabetes insipidus results when this neuro-endocrine system loses its functional integrity, either by reason of a hypothalamic lesion interrupting the path of motor-secretory impulses or by reason of replacement or destruction of the secretory tissue in the pars nervosa. In order that such loss of functional integrity may be clinically apparent, a certain amount of functioning anterior hypophysial tissue must be present. This diuretic function of the anterior hypophysis is probably mediated through other endocrine glands, and the evidence available suggests that the thyroid and pancreas are of importance in this respect.

Colloidal Aluminum Hydroxide for Peptic Ulcer.—Bennett and Gill believe that it is not justifiable to treat any patient with peptic ulcer by any medicinal substance with neglect of diet. Since many patients show great clinical improvement when treated by diet alone, it is difficult to assess the relative value of various alkalis. They have, however, treated some thirty outpatients of both sexes, between 29 and 72 years of age, suffering from gastric, duodenal or anastomotic ulcers by placing them on small frequent soft or fluid feeds with an alkaline powder taken one hour after each feed. After various periods each patient was asked to substitute aluminum hydroxide gel for the powder and to note any differences. All but two patients expressed a preference for the gel; nearly all were completely free from pain while taking this preparation, but five obtained no relief. The clinical impression was that the benefit was fully equal to that derived from the alkaline powder. Diarrhea, which is often very troublesome in patients under treatment with alkalis, was absent in all but one patient. Five patients had slight constipation, which was easily counteracted with liquid petrolatum. Aluminum hydroxide does not produce alkalosis.

Clinical Administration of Androgens.—Foss compared the efficiency of various preparations of androgens given by different routes in maintaining sexual function in a male postpuberal eunuch. The preparations were given in succession with short free intervals over a period of a year, and bland ointment and injections of sesame oil were given as controls. The minimal weekly effective dose of testosterone propionate when given by subcutaneous injection was 40 mg. To obtain an equivalent effect it was found necessary to give from two to three times this dose rubbed in as ointment, six times the dose rubbed in as tincture or twenty times the dose orally. Progesterone was found to prolong the action of testosterone propionate when given in conjunction with it. Total testicular extracts had little effect when given by injection and no effect when given by mouth.

Isotonic Sodium Bicarbonate Solution in Diabetic Coma.—Kirk reports two cases of diabetic coma with severe acidosis in which treatment with insulin did not rapidly bring about the expected improvement of the acidosis. Treatment with isotonic (1.3 per cent) solution of sodium bicarbonate immediately relieved the coma.

Trauma and Intracranial Tumors.—In a series of 150 consecutive cases of proved intracranial tumor, Cox found that trauma appeared to have been related to the onset of symptoms in four cases (2.6 per cent) or possibly five (3.3 per cent). In two of these, intracranial tumors were almost certainly present at the time of the injury. In one the microscopic study strongly suggested that the injury had caused focal changes within the tumor, about which a considerably enhanced rate of subdivision of the neoplastic cells was taking place. In two cases tumors were found in the regions of known sites of injury of a fairly severe grade. It is likely that in one of these the tumor did follow the injury; in the other it is possible that the tumor followed the injury, for, although a long period elapsed between its clinical onset and the injury, it was of a slowly growing type. It is thought that a brain containing a tumor is more likely to be injured by a blow than a normal brain. This seems to be true also for areas of the central nervous system containing simple malformations. A brain already the seat of inflammation would certainly have an enhanced susceptibility to injury. This may explain the apparently traumatic origin of many of the inflammatory and degenerative conditions of the central nervous system.

Cardiovascular Disturbances and Myxedema.—In this report Savy and his associates discuss the pathogenic and therapeutic aspects of the cardiovascular disturbances which are observed in the course of myxedema. They show that two types of cardiovascular disturbances can be observed in myxedema. To the first group belong those which can be traced directly to the myxedematous condition and which subside or disappear under the influence of organotherapy with thyroid. In the order of their frequency they are the diminution of voltage of the electrocardiographic tracings, more or less severe degrees of cardiac hypertrophy, some disturbances in tension and, in exceptional cases, anginal symptoms. All of these disturbances are benign and easily cured if they are not of too long standing. To the second type belong the lasting and incurable forms of cardiovascular disturbances. They are often aggravated rather than improved by thyroid therapy. Their prognosis is unfavorable and the connection with the thyroid insufficiency is uncertain or indirect. To this group belong coronaritis with or without anginal signs and with or without myocardial infarct; also considerable and persistent hypertensions and certain cases of cardiac insufficiency. The pathogenesis of these different types of cardiac disorders still involves numerous uncertainties. Although the tissular infiltration which is characteristic of the myxedematous state intervenes in the genesis of cardiac hypertrophy, and although the disturbances of neuromuscular excitation or of the cellular metabolism without doubt account for the modifications of the electrocardiographic voltage, on the other hand the role of thyroid insufficiency in the development of the arterial lesions is still only probable. The solution of the latter problem is of first importance for exact estimation of thyroid insufficiency as well as for the well founded total thyroidectomy in the treatment of angina pectoris and still more to throw light on the etiology and the pathogenesis of arterial disturbances, nearly all of which are as yet unknown.

*Statistical Data on Speed of Sedimentation in Gastroduodenal Ulcers. M. Demole and P.-E. Perret.—p. 194.

Speed of Sedimentation in Gastroduodenal Ulcers.—Demole and Perret report the technic and conclusions of their clinical examination of 102 cases of gastroduodenal ulcers. Only cases were included in which diagnosis was confirmed by the roentgenograms. In several cases retests were made. The age of the patients ranged from 20 to 90, with a preponderance in the years between 30 and 65 and with the classic predominance of men (seventy-eight) over women (twenty-four). The Westergreen technic was employed and resulted in the formation of three groups: normal (group 1), somewhat accelerated (group 2) and exceedingly rapid (group 3). Group 1 contained sixty cases (59 per cent), group 2 contained twenty-eight (27 per cent) and group 3 was represented by fourteen (14 per cent). The 102 cases show the following distribution: group 1, simple ulcers forty-one (80 per cent), complicated ulcers nineteen (37 per cent); group 2, simple ulcers eight (16 per cent), complicated ulcers twenty (39 per cent); group 3, simple ulcers two (4 per cent), complicated ulcers twelve (24 per cent). The high percentage of normal sedimentation (80) in simple ulcers was expected. Certain complications, such as perivisceritis, have no effect on sedimentation. Acceleration is seen in 63 per cent of the complicated ulcers. Grouped according to site (gastric, pyloric, duodenal) ulcers exhibited the following distribution: group 1, gastric twenty, pyloric six and duodenal thirty-four; group 2, gastric fifteen, pyloric three and duodenal ten; group 3, gastric eight, pyloric one and duodenal five. It can be assumed, they say, that in ulcers showing normal sedimentation the chances of improvement are better. Ulcers with accelerated sedimentation are likely to suffer relapse or lead to grave complications. Extensive variation of acceleration may appear in the same patient even within a few days, which emphasizes the need of retesting. On the other hand, a surprising stability in sedimentation may be observed extending over several years. Hemorrhages do not cause an immediate acceleration. Therefore, an apparently normal sedimentation may well have been preceded by a recent and even serious hemorrhage. The authors conclude that: 1. In the great majority of cases a "pure" gastroduodenal ulcer has no effect on the sedimentation speed. A foreign cause is nearly always found at the bottom of an ulcer clinically or roentgenographically simple but accompanied by accelerated sedimentation. 2. Complication of an ulcer by hemorrhage, stenosis, biloculation, perforation or induration does not invariably modify the speed of sedimentation. 3. Consequently, if an ulcer with rapid sedimentation is clearly established and nothing in the general condition of the patient, after detailed examination, can account for this acceleration, either the presence or the imminence of a complication must be suspected.

Chronic Pylephlebitis in Banti's Disease.—Croizat and Picard do not report new facts on the pathologic anatomy nor do they elucidate completely the still disputed pathogenesis of chronic pylephlebitis in the course of Banti's disease, but they aim to discuss the probable if not certain symptoms of pylephlebitis. They include under this term disorders of the portal system in the widest meaning of the word; that is, even lesions of the distal branches of the portal network. They analyze sixteen cases, some of which had already been surveyed in previous reports. Recently they observed a new case of pylephlebitis in Banti's disease and, since it demonstrates the diagnostic difficulties and the seriousness of the evolution, they describe and discuss this case in detail. It concerned a woman aged 35 who came under their observation in April 1938. The anamnesis revealed that she had had a keratitis during childhood and Pott's disease at the age of 14. The present disorder began in June 1937 with impairment of the general condition and with dyspeptic disturbances. Then ascites developed, which necessitated repeated punctures. After one of these punctures the existence of an enormous splenomegaly was observed and it was found that the patient had had attacks of diarrhea with bloody stools. For a while the patient's condition remained unchanged; under the influence of injections of diuretics the ascites remained stationary, and an existing anemic condition was improved by hepatotherapy. However, since neither the ascites nor the splenomegaly receded, a pylephlebitis was thought of and a surgical operation was decided on. The operation corroborated the diagnosis pylephlebitis. The ascites recurred after the operation, but after puncture it returned slowly. The patient died several months later. In the course of the necropsy it was found that the spleen presented the aspects of Banti's disease. Observations in this case and the analysis of other cases convinced the authors that chronic pylephlebitis is a frequent complication of Banti's disease. It seems to be definitely established that it is secondary to the splenic lesions and not a primary disorder. Unfortunately, pylephlebitis does not have a pathognomonic symptom and for this reason its diagnosis is difficult. Nevertheless, in the order of their frequency the most important symptoms are gastrointestinal hemorrhages, which the authors encountered in two thirds of the cases analyzed by them; then ascites and edema of the inferior members, which was observed in half of the cases. Laboratory methods furnish no information. Nevertheless, the correct diagnosis is of great importance because it contraindicates splenectomy, which, in the chronic cases of pylephlebitis, always results in death from acute, postoperative pylephlebitis.

Case of Congenital Hypoplasia of Right Kidney. E. Teposu, P. Bruda and I. Bratu.—p. 214.

Injection of Procaine Hydrochloride for Orchiepididymitis.—Imbert decided to treat acute cases of orchiepididymitis by blocking the terminations of the perideferential nerves by means of the injection of an anesthetic. He describes his experiences with this method by briefly reporting the clinical histories of twenty-three patients with acute orchiepididymitis, fifteen of which were of gonococcic origin, one of colibacillary origin and in seven of which the orchiepididymitis developed in the course of urinary disorders. He resorted to anesthetic blocking of the perideferential nerves also in one case of chronic orchiepididymitis. He uses a glass syringe of 20 cc. capacity, a fine and long needle and a 1 per cent solution of procaine hydrochloride. As a rule, it is necessary to anesthetize the point of puncture; nevertheless, if the patient is afraid or if the deferent canal is painful and congested, ethyl chloride may be applied at the point of injection. After disinfection of the skin the funicular portion of the cord is grasped and taken between the thumb and index finger of the left hand. The needle is attached to the syringe and with the right hand is introduced into the middle of the cord; injection is made in a manner so as to bathe the cord with the anesthetic. After the injection the patient remains in bed and the scrotum is elevated. Only one injection is necessary as a rule, but if on the following day the pain is not diminished it is best to renew the injection. A third injection may be made if necessary. The operation is simple and harmless; it never gives rise to complications, except that a slight swelling may exist for several days at the site of injection. The analgesic effect of the treatment becomes manifest at the end of one or several hours, the temperature decreases and the general condition and the appetite improve. The scrotal edema disappears and the thickening of the tunica vaginalis diminishes. From the second day on, the scrotum becomes wrinkled and palpation of the testes and of the epididymis is possible. After three days the patient can resume his occupation if he so desires, but if possible he should rest a little longer; for, although the pain and inflammation may have disappeared, the anatomic cure is not yet complete. The author gained the impression that approximately two weeks is required for anatomic cure in gonococcic orchiepididymitis and three days in the orchiepididymitis with banal infection. He also observed that for the simple orchitis which develops in urinary disorders the aforementioned treatment is sufficient; if a colibacillary orchiepididymitis exists, it is necessary to treat the septicemia. Vincent's serum or autovaccine gives the best results and is an excellent adjuvant to the procaine hydrochloride injections. In gonorrheal orchiepididymitis, the author employs gonococcic vaccines and calcium salts in addition to the procaine hydrochloride. Regarding the effect on spermatogenesis, the author says that he observed spermatozoa in normal numbers and of normal vitality in a subject in whom the orchiepididymitis had involved both sides. Thus he hopes that the risk of azoospermia is less after the described treatment with procaine hydrochloride than in some other ambulatory methods, such as intra-epididymal injections.

*Investigations on Persistence of Agglutinogenic Power in Old Vaccines. B. Babudieri.—p. 67.
Action of Para-Aminophenyl-Sulfonamide (Sulfanilamide) and Its Derivatives on Development and Evolution of Experimental Streptococcic Infection in Rabbits. F. Vacirca.—p. 81.

Agglutinogenic Power in Old Vaccines.—Babudieri determined the persistence of antigens in typhoid-paratyphoid and typhoid-paratyphoid-cholera vaccines, as shown by the agglutinogenic power of the vaccines. He experimented on rabbits by using vaccines prepared two or three years previously with either formaldehyde or phenol as an antiseptic. The author found that (1) the dose of the vaccines, within certain limits, has no influence on the produced amount of agglutinins, (2) the H and O antigens are well preserved but the Vi antigen, which exists in freshly prepared vaccines, does not exist in old ones and (3) the O antigen is not entirely thermostable. Therefore, when bacterial suspensions which contain the O antigen are placed under a temperature of 100 C. for two hours and then used in making quantitative determinations of the agglutinins in a given blood serum the results may be false.

*Cerebral Metastatic Tumors. R. Soto Romay.—p. 89.
Leptomeningeal Neuroblastoma: Cases. R. Carrillo and M. Oribe. —p. 172.

Cerebral Metastases.—Soto Romay made a clinical and anatomic study of twenty cases of cerebral metastases out of a group of 286 cases of cancer of different locations in which a necropsy was performed. The author found that the greatest incidence for the production of cerebral metastases is for patients between 30 and 40 years of age in either sex. Epitheliomas of the lung, the breast and the adrenals are the most frequent tumors which give cerebral metastases. The number, size, distribution and exact location of the metastases vary in different cases. The brain, the cerebellum and in rare cases the optostriate nuclei are the nervous structures most frequently involved by metastases, which may be isolated or multiple and involve one or various structures at the same time. Frequently the cerebral symptoms are the first ones which show the presence of cancer in some other organ. The symptoms of cerebral metastases are similar to those given by primary cancer of the brain. In the majority of the cases, intracranial hypertension and edema of the papilla exist. The diagnosis of cerebral tumor is done by the presence of intracranial hypertension and edema of the papilla in the absence of the various conditions which may cause hypertension (acquired hydrocephalus, serous meningitis, encephalitis and other cerebral conditions). It is confirmed by iodoventriculography (x-ray examination of the brain after introduction of opaque substance). A diagnosis of probable cancerous metastases is made in the presence of intracranial hypertension, with edema of the papilla and actual existence or a history of cancer in the past in the given patient. Cancer of the lung, either primary or secondary, does not exist in all the cases of cerebral metastases. The evolution of cancerous metastases depends on the location of development of the tumor, probable compression of important structures, malignant type of the given tumor and general conditions of the patients. As a rule the metastases follow an evolution to final cachexia in from two to six months. Certain local conditions, such as cerebral softening and cerebral hemorrhages near to or far from the tumor, accelerate the evolution of the tumor. The microscopic type of cancer metastases of the brain is not necessarily the same as that of the primary tumor. The metastatic nodules cause infiltration and destruction of the nervous tissues.

*Results of Surgical Treatment of Hernia. E. von Novák and A. Rigler. —p. 342.

Prevention and Treatment of Tetanus.—Gottesbüren points out that the tetanus bacillus is not nearly as ubiquitous in its habitat as Clostridium welchii. Zeissler in his study of anaerobic flora found that, while Clostridium welchii was found in 100 per cent of the specimens of soil examined, the bacillus of tetanus was found in only 27 per cent. The generally accepted view that the incidence of tetanus depends on the nature of the soil is contradicted by Hinstorff, who did not find any such relationship in a study of 567 cases occurring in 1928 and 1929. The author discusses prophylaxis of tetanus under three headings: surgical prophylaxis, passive immunization and active immunization. Friedrich's method of excision of the wound within the first six hours is too radical and not applicable to cases of extensive traumatization. Adequate treatment,

in the opinion of the author, consists of enlarging the wound so as to expose all pockets and dead spaces and to remove blood clots, necrotized tissue and particularly the foreign bodies present. The wound is kept open by gentle packing. The general support of the organism is of the greatest importance. The author advocates the injection of 2,500 units of antiserum (1,500 American units) within the first twelve hours, the sooner the better. The hypodermic method is preferred because of its somewhat slower absorption and, therefore, longer action than is the case with the intramuscular or intravenous methods. From two to five times this dose is advisable in territories with reputation for tetanus. The duration of the protective effect of serum is from seven to ten days. Because operative procedures undertaken some time after the injury have a tendency to reactivate the latent tetanus infection, it is advisable to repeat the dose. Cases of this type are to be anticipated by a combined passive and active immunization. The latter was made possible by the work of Ramon and Löwenstein, who detoxified the tetanus toxin by adding formaldehyde to it. Active immunization presents the advantage of offering definite protection against tetanus without any of the untoward effects of the passive immunization, such as serum shock and serum sickness. The results in the treatment of developed cases of tetanus are still far from satisfactory. Cases with an incubation period of less than ten days give a mortality of 70 per cent. The tendency is to use enormous doses of antiserum. When blood transfusion is indicated in a case of tetanus, the author feels that it is of advantage to use a donor who had been actively immunized against tetanus.

Surgical Treatment of Hernia.—Von Novák and Rigler state that all hernias, with the exception of those occurring in infants, can be cured by surgical intervention. It is, however, essential to operate early in order to avoid surgical procedures on huge hernias in elderly persons. The wearing of a truss is to be permitted only when definite indications exist and only on the prescription of a doctor. A herniotomy presents definite hazards for persons with organic disease. This is particularly true of large hernias in elderly individuals. For this reason such patients should be submitted to a thorough examination. Elderly patients should be operated on only for definite indications and preferably during the summer time. All herniotomies should be performed as far as possible under local anesthesia and every means employed to avoid straining. The authors consider a herniotomy as an operation requiring considerable technical skill and therefore not to be entrusted to a beginner. In the postoperative period the patients are kept in bed eight days and are to abstain from work for not less than six weeks. Since bilateral hernias do not recur oftener than a unilateral one and since a patient subjected to a bilateral herniotomy is exposed to a greater hazard than one subjected to a unilateral herniotomy, one should carefully weigh the question of performing a bilateral operation at the same time. The mortality in a series of 3,604 herniotomies, both simple and incarcerated, carried out in the course of fifteen years at the surgical clinic of the Pázmány Péter-Universität, Budapest, amounted to 2.3 per cent. The mortality amounted to 1 per cent for the simple cases and 15.2 per cent for the incarcerated cases. Disturbances in wound healing occurred in 6.4 per cent and recurrences in 7.9 per cent.

Modification of Hemopoiesis by Sternal Puncture.—Stodtmeister and Büchmann state that the present status of knowledge seems to indicate that the cellular composition of the bone marrow is identical in the different parts of the skeletal system. In employing sternal puncture as a diagnostic method, the question arises whether this intervention might perhaps modify the function of the bone marrow in its entirety. It is the object of this report to find an answer to this question. In a number of patients who had undergone sternal puncture the reticulocytes and leukocytes were determined at hourly intervals. Since it seemed desirable to make the studies on patients in whom the bone marrow was in a state of heightened reactivity, several patients with pernicious anemia were selected for these tests. However, studies were made also on patients with secondary anemia and on a patient with inflammatory leukocytosis. In addition to these clinical tests, experimental studies were made on dogs. Ten medullary punctures were made on these animals in the course of sixteen days. Some of the punctures were made on successive days and, to increase further the irritating action on the bone marrow, the authors on two days punctured not only the sternum but also the tibia of the dogs. The first six punctures were preceded as well as followed by a complete hemogram and the reticulocytes were counted in the blood as well as in the bone marrow. In the last four punctures only the leukocytes and reticulocytes were counted before and after the puncture. The authors report the results of these tests and, in evaluating them, they stress that it should not be overlooked that reticulocytes and leukocytes are subject to spontaneous fluctuations. They reach the conclusion that an intervention on the living bone marrow, such as the sternal puncture represents, has no effect on the cellular composition of the blood. Moreover, it is a minor intervention which can be made without hesitancy even in ambulatory practice. The puncture can be made pain free by infiltrating the skin and the periosteum with procaine hydrochloride. The pains during the aspiration can be counteracted by administering morphine before the puncture.

*Problem of Sterile Marriage: Treatment of Postgonorrheal Sterility in Man. K. Ehrhardt.—p. 369.
*Caisson Disease in Bridge Construction. R. Koenig.—p. 370.

Postgonorrheal Sterility in Men.—According to Ehrhardt the treatment of postgonorrheal male sterility has heretofore been regarded as giving little promise of success; but he is convinced that the surgical method first introduced by Hagner of Washington will prove successful in many cases. The method consists in making an anastomosis between the epididymis and the vas deferens above the part that has been obliterated by the gonorrheal inflammation. Following its exposure the epididymis is split and examined for the presence of spermatozoa; the lumen of the vas deferens is opened and the two openings are joined. It is advisable to open the vas deferens not too high up, so that if the first intervention is unsuccessful a second one can be made. The author admits that he considered this method at first with skepticism, but the patient to whom he first suggested it was willing to try any method that might prove successful, the more so since, as regards function, nothing could be lost and something might be gained. Moreover, the intervention is comparatively simple. In the aforementioned case motile spermatozoa could be detected in the semen three weeks after the operation, and two months later the wife was found to be pregnant. The pregnancy resulted in the birth of a normal child. The author cites two other cases in which this operation was performed, admitting however that the percentage of successes cannot be estimated as yet. Nevertheless he thinks that many cases of postgonorrheal sterility will respond to this surgical procedure.

Caisson Disease.—Koenig observed a considerable number of cases of caisson disease in workers constructing bridge piers under rather difficult conditions, that is, under a pressure of 30 meters of water (excess pressure of about three atmospheres). He illustrates the varying symptomatology of caisson disease with four case histories. The most characteristic

symptoms in the first case were muscular and articular pains. The author says that these symptoms are the chief complaints of 62 per cent of the workers with caisson disease. The pains vary in severity from mild forms to severe forms with paralysis. In most cases unpleasant drawing sensations near the joints appear about thirty minutes after the worker comes out of the decompression chamber. The intensity of these pains is not uniform; they may disappear for seconds and then reappear with greater intensity. They may flash from one joint or group of muscles to another one. Paralytic symptoms of a spastic nature are comparatively rare; more frequent are reduced muscular tonus and weakened or abolished patellar tendon reflexes in the presence of bilaterally positive Babinski reflexes. The duration of the symptoms varies greatly. In the second case the light red foamy sputum, severe cyanosis and dyspnea indicated a partial acute pulmonary edema. The dark blue marmoration of the skin of the trunk indicated paralysis of the peripheral vessels. In the third and fourth cases the symptoms were typical of severe circulatory disturbances and of impairment of the central nervous system. The conditions of collapse may become so severe that they threaten life. The symptoms of central impairment are vertigo, spontaneous nystagmus, excessive perspiration, nausea, vomiting and severe fatigue. As the most important therapeutic procedure the author recommends immediate placement in the compression chamber. The pressure should be brought to a point at which the symptoms disappear and it should be kept there for from fifteen to thirty minutes. The subsequent decompression should be slow. In a case in which consciousness has been lost, the pressure must be increased slowly so as to avoid rupture of the tympanic membrane. The administration of cardiac and circulatory remedies may prove a valuable addition to the use of the compression chamber.

Impairment of Lung by Irradiation.—Bauer thinks that, in view of the large number of intensive irradiations of the thorax, ray injuries of the lung must be more frequent than the literature on the subject indicates. He reports the clinical and roentgenologic aspects of a case of roentgen ray injury of the lung which terminated in death. A mediastinal tumor, which had spread through the left upper field and which probably was a thymogenic carcinoma, provided the occasion for three series of irradiations. The doses of roentgen rays did not exceed those generally applied in cases of malignant pulmonary tumors. In the first series of irradiations 7,810 roentgens was applied to five different fields in the course of six weeks. Three months later, 5,600 roentgens was administered to the same five fields in the course of three and one half weeks, and after another three months 3,900 roentgens was applied to four fields in the course of four weeks. The author admits that the third series was applied after a shorter interval than is usually the case, for, as a rule, the third series is applied only after an interval of six or nine months, but in this case its earlier administration seemed justified in view of the rapid exacerbation, which was regarded as the manifestation of renewed tumor growth. The necropsy revealed, in addition to the extensive ray induration that resulted in death, a large indurated body in the upper mediastinum, in which tumor cells were no longer demonstrable. On the basis of a review of the literature the author discusses the factors that may lead to severe ray injuries of the lung. He thinks that, in addition to the size of the dose and its distribution as regards time and space, inflammatory, pulmonary processes and an individual predisposition to an inflammatory-connective tissue reaction of the lung play a part. Because it is difficult to estimate the depth dose in thoracic irradiations, great caution is required in such irradiations.

*Hodgkin's Disease: I. Experimental Investigations on Etiology of Hodgkin's Disease. P. Uhlenhuth and K. Wurm.—p. 205.

Etiology of Hodgkin's Disease.—Uhlenhuth and Wurm base their studies on the etiology of Hodgkin's disease on the assumption that it might be an infectious disease; they regard this theory as justified in view of the clinical course, of the character of the pathologic-anatomic changes and of epidemiologic observations. Reviewing the literature on the etiology of Hodgkin's disease, the authors point out that a tuberculous etiology has been discussed repeatedly. However, on the basis of the results obtained so far they reject a tuberculous etiology but think that it is necessary to make further investigations on this problem. Positive tuberculin tests and positive serologic reactions for tuberculosis are important in patients with Hodgkin's disease because they suggest the simultaneous existence of a tuberculosis and make it necessary to be cautious in the application of roentgen therapy. The types of streptothrix and the diphtheroid bacilli are of no significance in the etiology of Hodgkin's disease and the same can be said of the granular antiformin-fast rods described by Fränkel and Much. So far it has been impossible to corroborate the presence of Gordon's elementary bodies in Hodgkin's disease. But although Gordon's test has proved a failure as regards the explanation of the cause of Hodgkin's disease, and although this test can no longer be regarded as a corroborating factor for the virus theory of Hodgkin's disease, it is nevertheless valuable as a diagnostic aid and it is especially helpful in the microscopic examination of lymph nodes that have been obtained by biopsy; this was demonstrated by the authors in three cases. The agent that is active in Gordon's test is not restricted to human subjects but has been observed also in the spleen of white mice. Wurm's suggestion that the agent which is pathogenic for the brain of rabbits (Gordon's test for Hodgkin's disease) represents a constituent of eosinophil cells is supported by observations made by the authors. This substance seems to have some connection with a body that is identical with the Charcot-Leyden crystals. The authors did not succeed in transmitting Hodgkin's disease to animals. Efforts to develop a diagnostic sero-reaction remained without success.

*Results of Pneumothorax Therapy in Presence of Giant Cavities. Cellarius and Lemberger.—p. 382.
Supplementary Apparatus for Thoracoscopy. E. Dorn.—p. 386.

Pneumothorax Therapy and Giant Cavities.—Cellarius and Lemberger investigated the fate of giant cavities under the influence of pneumothorax therapy. Their studies were made on a material comprising eighty-seven cases of giant cavities with a diameter of 5 cm. or more. Especial attention was given to the presence of exudate and adhesions. The authors show that the opinions are still divided regarding the role of an exudate in the presence of an artificial pneumothorax. Whereas about one third of the investigators are of the opinion that the advantages and disadvantages are about even, about one half of them think that the disadvantages exceed the advantages and the remaining number emphasize only the disadvantages of the exudate. Only exceptionally is it suggested that the serous exudate is desirable by reason of its favorable effect. As regards the adhesions, it is generally

conceded that those which keep the cavity extended exert a harmful effect. However, not all adhesions exert the same unfavorable effect. The authors classify their eighty-seven cases of giant cavities according to whether they were uncomplicated by adhesions and exudates or complicated by either or both of these. In the first group of eleven cases neither adhesions nor exudates existed, in the second group of ten cases there were exudates but no adhesions, in the third group of thirty-eight cases there were adhesions but no exudates and in the fourth group of twenty-eight cases there were both adhesions and exudates. Summarizing the results obtained with pneumothorax therapy in eighty-seven cases of giant cavities, the authors say that 63.25 per cent of favorable results indicate that at least an attempt should be made with this type of treatment. In some cases pneumothorax therapy fails because of extensive adhesions, and surgical treatment becomes necessary. Pneumothorax therapy produced the most favorable results (100 per cent efficiency) in cases without adhesions and exudate. Equally favorable were the results in the cases with mediastinal and medial adhesions at the apex, when exudate developed. Of the cases without such adhesions but with exudate, 30 per cent failed to respond favorably to pneumothorax. This seems to indicate that the mediastinal adhesion gives a more secure point of attack for the diagonal traction and pressure effect of the exudate. The authors found that pleural exudates are advantageous in all cases with adhesion. To be sure, they disregarded the mechanically ineffective angular and small exudates. The authors do not agree with the investigators who regarded an exudate as a complication that is always undesirable. They think that this attitude is justified only in the cases in which there exists a total pneumothorax without pleural adhesions. Even in these cases the exudate may help in overcoming the stiffness of the wall of a cavity. The authors think that exudates are an advantage in all cases with adhesions, provided of course that a mechanical compression is possible. They emphasize the favorable effect of pneumothorax therapy in giant cavities that are located near the hilus; this is important, because they do not readily yield to other forms of collapse therapy.

Pathogenesis of Hepatic Changes in Goiter.—According to Zeldenrust and van Beek, the hepatic changes that are detected in necropsies after exophthalmic goiter differ widely. They consist of atrophy, fatty degeneration, stasis, cirrhotic changes and occasionally acute yellow atrophy of the liver. The opinions about the pathogenesis of these changes differ just as widely as the changes themselves. Whereas one group of investigators regards the hepatic changes in exophthalmic goiter as resulting from toxic impairment of the liver, others ascribe the greatest importance to the circulatory disturbances of cardiac origin. Still another point of view was advanced by Rössle, who in the livers of patients with exophthalmic goiter noted irregular blood perfusion which did not always concur with the aspects of cardiac stasis. He also detected signs of pericapillary edema and he regarded these changes as signs of serous hepatitis, which, like the degeneration of the hepatic cells, he supposed to be of a toxic nature. Necrosis he regarded as the result of a more severe toxic action. After citing investigators who agreed with Rössle and some who disagreed with him, the authors describe the clinical histories of and the postmortem observations in two cases and then give a tabular survey of fourteen cases that were studied at the pathologic laboratory of the university of Leyden. In the summary they emphasize that exophthalmic goiter is frequently accompanied by atrophy of the liver following degeneration of the hepatic cell. Occasionally the hepatic impairment is so severe that necrosis of the hepatic tissue does occur and that the clinical and morphologic aspects indicate acute yellow atrophy of the liver. Moreover, acute as well as chronic signs of cardiac stasis can be observed. The degenerative changes in the hepatic cells explain the often irregular distribution of hepatic stasis. The authors observed no indications of serous hepatitis. Although they admit that the blood distribution in the liver may be dependent also on nervous factors, their morphologic investigations did not reveal that these factors were important for the changes in the hepatic cells, because the manifestations which supposedly are indicative of vasomotor disturbances can be interrupted also as the result of the concurrence of atrophy, degeneration and cardiac stasis. The clinical and morphologic aspects of the heart justify the assumption that they have a pathogenic role in hepatic stasis.

Coagulation of Blood and Hemophilia.—Bendien and van Creveld studied the coagulation-promoting activity of fresh normal serum and plasma. They found that in plasma the coagulation-promoting factor is attached to fibrinogen; in serum this factor is not ultrafiltrable and is present in a coarse-disperse phase. However, the factor is not identical with nor attached to euglobulin. They describe a method for precipitation from the serum of the so-called coagulation globulin, the substance which promotes coagulation. It proved possible to prepare solutions of coagulation globulin which promoted coagulation more effectively than did the original fresh serum. When these solutions were kept in the cold or in a sterilized condition their coagulation-promoting activity decreased only slowly. The authors describe the effects of oral, intramuscular and intravenous administration of such solutions on the coagulation time of some hemophilic patients. Only with the intravenous injections were distinct reductions of the coagulation time of the blood observed. A modification of Eley's method is described by means of which the authors could prepare from human placentas solutions that were poor in protein content but had a strong coagulation-promoting activity in vitro on hemophilic plasma and blood. No therapeutic effect was seen of the oral or intramuscular administration of these products in hemophilia or of the oral administration of the original Eley product. Clear sterile solutions could be prepared from placentas which repeatedly could be injected intravenously into animals without detrimental effect. The same solutions could repeatedly be injected into patients with hemophilia also without a disagreeable reaction; the clinical results as regards the effect on the coagulation time were, however, distinctly inferior to the experiences with the serum products, although in vitro the coagulation-promoting influence of the placental extracts was much stronger. In one patient with hemophilia, who suffered from a prolonged renal hemorrhage and who did not react even to two blood transfusions, the hemorrhage ceased after one intravenous injection of 4 cc. of the placental extract. The authors discuss the possible identity and the protein-like character of the coagulation-promoting substances present in serum and in placental extract and suggest a relation of this "coagulation-globulin" to prothrombin.

Clinical Aspects of Giardiasis.—De Muro says that before the World War most authors considered Giardia intestinalis a harmless saprophyte. This opinion was based on the fact that Giardia sometimes exerts no pathogenic action at all and may be found in healthy persons. However, it is known from bacteriology that the presence of healthy carriers does not exclude pathogenic action. The author mentions several epidemics of giardiasis that were observed during the war and then reviews the literature on clinical observations and experimental and

pathologic data. His own studies were made in forty-five cases of giardiasis. It was found that giardiasis appears under four different clinical forms: enterocolitis, rectocolitis, enterohepatobiliary syndrome and pancreatic insufficiency. Enterocolitis was the form observed most frequently. It existed in twenty-eight (62.2 per cent) of the cases. Because the symptomatology is similar to that of amebiasis, the differentiation may prove difficult. Giardia enterocolitis displays at the beginning scanty phenomena. The main feature is the abnormality of the stools. As a rule the patient goes through a period with two diarrheal or soft stools a day, alternated by periods of normality or constipation. The stools resemble cattle dejections, yellowish brown with pearl gray shades, owing to the great abundance of mucus. The smell is fetid and the reaction alkaline. As a rule there is no blood. After some time the irregular movements of the bowels become associated with slight crises of pain, diffused at times over the entire abdomen and sometimes localized in the cecocolic region, in the transverse colon and in the colic flexures, particularly the hepatic one. After a long time the general condition becomes impaired. Many patients present a more or less profound asthenia with considerable pallor of the skin and of the visible mucous membranes, presenting the aspects of slight hypochromic anemia with no leukocytosis and sometimes with a few eosinophils. Besides derangement of the bowels, asthenia and slight anemia, the principal symptoms, there are other symptoms. The tongue is somewhat reddened and often coated, the breath is fetid, the appetite lacking or fanciful. The digestion is slow and difficult and is at times accompanied by slight stomach cramps and decided meteorism. Chemical tests show as a rule gastric hypochlorhydria. Some patients present nervous disturbances, which become more severe when the intestinal troubles increase. The rectocolitic form of giardiasis was observed in three of the author's patients. Two of these patients had a catarrhal form and one an ulcerative one. The author shows that proctosigmoidoscopy has greatly increased the knowledge of this form. The enterohepatobiliary syndrome, in which there exists at the same time duodenitis, cholecystitis and hepatitis, was observed in fourteen of the forty-five cases. The author further describes studies on pancreatic insufficiency in giardiasis. On their basis he feels justified in asserting that in chronic giardiasis there often exists a latent pancreatic insufficiency.

*Etiology of Hydronephroses. J. C. Christoffersen.—p. 93.
Simple Preventive Treatment for Determination of Vitamin D by Direct Measurement of Width of Epiphysis Zone. P. Schultzer.—p. 101.

Etiology of Hydronephroses.—Christoffersen discusses the etiology of 127 cases of hydronephrosis, in all of which the diagnosis was verified by x-ray examination, in many on operation and in some at necropsy. Forty-one cases (thirty-six infected) were calculous hydronephroses, thirty-one were due to aberrant blood vessels, seventeen to ureteral anomalies, eight to nephroptosis with a kink in the ureter, five to compression of the ureter and four to cicatricial strictures in the ureter; twenty-one are ascribed to dynamic causes. Operative treatment was conservative as far as possible. Primary nephrectomy was necessary in three cases, secondary nephrectomy in two.

*Treatment of Lymph Node Metastases from Carcinoma of Lip and Oral Cavity. R. B. Engelstad.—p. 105.
*Papilledema and Hypertension. I. Aasland.—p. 108.
Four Cases of Perilunar Dorsal Luxation of Wrist. K. Harstad.—p. 110.

Lymph Node Metastases from Carcinoma of Mouth.—Engelstad states that, of 135 patients with carcinoma of the oral cavity and 141 with carcinoma of the lip treated during a three year period, 32.6 and 65.2 per cent respectively are well after an observation period of from two and a half to six years. Of the patients with oral carcinoma without glandular metastases 61.1 per cent are well and of those with glandular metastases 17.4 per cent, while of those with lip carcinoma without glandular metastases 87.7 per cent and of those with glandular metastases 48.2 per cent are well. The author concludes that in not a few cases of glandular metastases from carcinoma of the oral cavity and a fairly large number of those from cancer of the lip teleradium treatment effects a cure, and in other cases the treatment may make inoperable cases operable. The primary treatment of these glandular metastases should always be radiologic; teleradium is used in most cases. If after about eight weeks the results are not satisfactory or if later there is recurrence or new metastases appear in the irradiated region, total bloc resection of the affected glandular area is done. The local effect of the combined treatment, he says, is good. The mortality in his material was high because a large number of the glandular metastases were inoperable; in many cases, partly also because the primary tumor was too advanced to be controlled, and in some cases probably because the cancer at the time of admission had extended beyond the field of the regionary glands. Prophylactic treatment of the glandular areas was not usually carried out, except irradiation of the submandibular region in connection with treatment of the primary cancer, but it is believed that a more extended irradiation would probably be valuable in oral cancers.

Papilledema and Hypertension.—Aasland says that, while the etiology of the various disorders in which choked disk may appear differs, the common factor in all is arterial hypertension. He thinks that the extreme form with intracranial pseudotumor occurs only in malignant hypertension. The picture of pseudotumor depends on arterial hypertension in the cranial blood vessels with secondary symptoms of circulation insufficiency in the form of general edema and increased intracranial pressure. The increased pressure of the cerebrospinal fluid which is often present in malignant hypertension is assumed to be an accessory factor in the mechanism of choked disk. Two cases of intracranial pseudotumor associated with malignant hypertension are reported. There were bilateral papilledema of 5 and about 7 diopters respectively. The blood pressure varied from 230 to 250 mm. of mercury. In the second case the pressure of the cerebrospinal fluid rose to 360 mm. No signs of renal disease were established in either case. Necropsy revealed no evidence of cranial tumor. In spite of recommended treatment, such as intravenous hypertonic solutions, repeated lumbar puncture and depressive craniotomy, the prognosis is grave. According to statistics 90 per cent of the cases are fatal within two years after the beginning of the hypertensive changes in the eyeground, and most of the remaining 10 per cent within the next two years.

1: 147-206 (Jan. 21) 1939

Treatment of Tuberculosis of Larynx. T. Blomroos.—p. 147.
*Indications and Technic in Treatment of Cancer of Larynx. P. Frenckner.—p. 152.

Treatment of Cancer of Larynx.—Dividing laryngeal cancer into five groups according to the treatment called for, Frenckner says that in group 1, with cancer which involves only the anterior two thirds of one vocal cord and does not extend to the anterior commissure, treatment may be operative, endolaryngeal removal in the earliest stages, or laryngofissure with excision, or radiologic, a combination of the operative and radiologic methods best insuring freedom from recurrence. In group 2, with cancer of one vocal cord invading the anterior commissure of the other vocal cord, radiology offers the greatest advantage. In group 3, with more widespread but still limited unilateral cancer, and in group 4, with more extensive intralaryngeal cancer, laryngectomy followed by radiotherapy is the method of choice. In group 5, with extralaryngeal cancer, only radiologic treatment is to be considered; operative treatment is possible only in certain restricted tumors with particularly favorable location. As to technic, a U-formed cut with strong flap covering the field of operation is advised, with removal of the larynx from below. A special tampon cannula is recommended. About half of the author's laryngectomized patients learn to speak with the esophagus well enough to carry on in their work, use the telephone and so on, from 35 to 40 per cent produce a weak and indistinct voice with which they make themselves understood in their immediate environment, and a small fraction have to depend on an artificial voice box. The material is mostly from the last five years, but the results as far as can be judged from a recent review seem to compare favorably with statistics from other countries.

FACTORS TENDING TO MINIMIZE THE PROSTATECTOMY HAZARD

WITH PARTICULAR REFERENCE TO WOUND ASEPSIS

EDWIN DAVIS, M.D.

OMAHA

The average person has a natural dread of prostatectomy. In fact the average physician or general surgeon has no real conception of the safety with which this procedure may be carried out via the perineal route with sacral block anesthesia. I presume to carry this statement even further by suggesting that probably only relatively few in a select audience of urologic surgeons have a full realization of the opportunity for precision and accuracy which this procedure affords and realize that almost complete elimination of surgical hazard has become possible.

Mortality figures may be mentioned merely as a matter of record and with no purpose other than to emphasize the possibilities resulting from systematic elimination of the various hazards. My own mortality rate for perineal prostatectomy in a series of cases previously reported on a number of occasions and now totaling 741 is 2.7 per cent. Every postprostatectomy death, from any cause whatever, prior to dismissal from the hospital has been counted. This record includes two consecutive series, totaling 121 and 107 respectively, each without a single death. There has been but one death in the last 144 consecutive cases. Others, particularly Young,[1] Hinman[2] and Cecil,[3] have reported comparable figures, in fact better figures. There is no reason why a limited few should have a monopoly on perineal prostatectomy, since the technic may be mastered by any one with moderate skill and sufficient determination and patience. Young[1] has mentioned that four successive residents at the James Buchanan Brady Urological Institute of Johns Hopkins Hospital performed 190 consecutive prostatectomies on unselected patients from public wards with only three deaths (1.5 per cent).

Amazing though this statement may seem, there is no reason why the mortality rate of perineal prostatectomy in the aged and debilitated should not be made to compare favorably with that of herniotomy in the young and robust.

My present purpose is to enumerate and to discuss briefly the various factors which are responsible for this conspicuously low mortality rate and which have placed perineal prostatectomy in the category of so-called finished operations. This term seems permissible because (1) the mortality rate so closely approximates the "normal" death rate[4] for the age of 70 and because (2) questionnaire records[5] show that, of aged persons, many of whom have unrelated ailments and symptoms which might readily be confused, 82.3 per cent voluntarily classify themselves as "well" and 98.8 per cent as "well or improved."

The lowering of the mortality rate has been essentially a process of elimination of the various hazards one by one. The chief hazards, together with the "remedy" or method of control of each, are listed in the accompanying table.

UREMIA

As known by every one (but ignored by many), the answer to the uremia question is preoperative drainage by retention catheter or via the suprapubic route for days, weeks or many months, insistently and inexorably carried out, for as long as may be necessary, regardless of urging to the contrary by patient, relatives or physician. The surgeon has but few privileges, but one of these is to decline to operate. The necessity for adequate drainage is too well understood to require further comment. One might as well seriously discuss the advisability of hemostasis. There is little excuse for deaths due to postprostatectomy uremia.

INFECTION

A brief discussion of postprostatectomy sepsis, together with the presentation of a method tending to decrease this hazard, is the chief occasion for this paper.

Prostatectomy without infection of the urinary tract is impossible. In fact a period of fever during the time of preliminary drainage is decidedly the rule rather than the exception and is to be welcomed because of the immunity supposedly conferred. At any rate, high postoperative temperature reactions are relatively far more frequent among those who have not gone through a period of preoperative fever. Time and the natural processes of immunity, with the aid of free dependent drainage, tend automatically to take care of such infections of the urinary tract. In fact except in the debilitated and patients with additional lesions of the urinary tract, gross pyuria ordinarily disappears spontaneously several weeks after perineal prostatectomy.

Read before the fiftieth annual meeting of the American Association of Genito-Urinary Surgeons, Absecon, N. J., May 4, 1938.

1. Young, H. H.: Surgical Treatment of Prostate, J. A. M. A. **110**: 280 (Jan. 22) 1938.
2. Hinman, Frank: The Modern Operation of Plastic Perineal Prostatectomy, Tr. Am. A. Genito-Urin. Surgeons **30**: 265, 1937.
3. Cecil, A. B.: Preoperative Treatment of Prostatic Obstruction, Surg., Gynec. & Obst. **58**: 630 (March) 1934.
4. According to the American experience tables of mortality, of 100 persons alive at the age of 70, six may be expected to die before reaching 71. Carrying this comparison to its extreme in absurdity, if the period of hospitalization for prostatectomy was one year, the "normal" death rate might be said to be more than twice the postprostatectomy death rate.
5. Davis, Edwin: Analysis of Results in 378 Consecutive Cases of Perineal Prostatectomy, Tr. Am. A. Genito-Urin. Surgeons **24**: 387, 1931.

Postprostatectomy systemic infection, however, is a different matter. I refer to the occasional occurrence of postoperative invasion of the blood stream, characterized by chills, a high temperature and evidence of sepsis, and have in mind three postprostatectomy deaths in my own series directly attributable to this cause. Were evidence of invasion of the blood stream

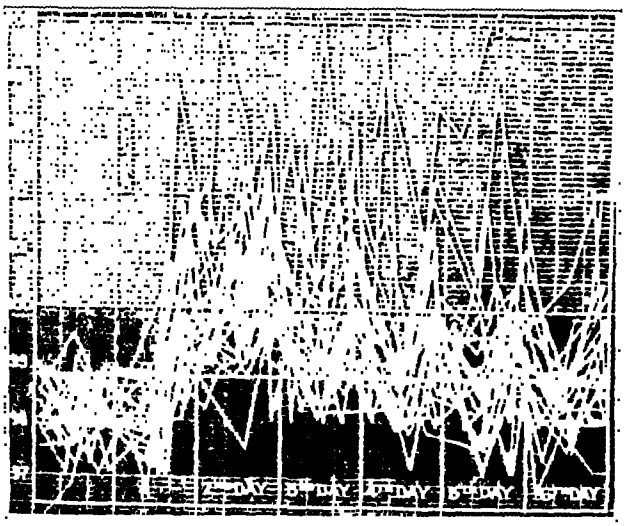

Chart 1.—Temperature reaction following perineal prostatectomy, demonstrated by superimposed temperature curves from twenty-five consecutive cases. In order to make the elevations more conspicuous, the portion of the rulings below the 100 F. line has been blurred. Note the great excess of rulings above the 100 F. line as contrasted with chart 2. Note also the conspicuous absence of rulings below the 99 F. line on the second postoperative day.

necessary, it might be stated that one of these patients had multiple small staphylococcic abscesses distributed over the trunk and extremities.

Since the assumption seemed permissible that such systemic reactions are due to the liberation of virulent bacteria into fresh "unvaccinated" tissues, an attempt at wound antisepsis during operation was considered to be worth the effort. A routine surgical technic was adopted, including irrigation of the urethra and bladder with a 2 per cent mercurochrome, alcohol and acetone solution [6] immediately before incision and flooding of the wound with the same solution immediately before closure. Wound sterilization was not expected, but wound antisepsis, with a consequent decrease in numbers and virulence, or in the "dose" of bacteria to which fresh tissues were exposed, was hoped for. The use of this technic was started in January 1932, as suggested by Harris,[7] who had previously reported favorably on a similar technic as applied to suprapubic prostatectomy.

If the assumption is permitted that the temperature is a reliable index of the degree of sepsis, it may be said that this technic has given distinctly beneficial results. Moreover, there have been no more deaths directly attributable to sepsis, such as had previously occurred. This improvement may be graphically demonstrated. Charts 1 and 2 represent the superimposed temperature curves of the first postoperative week in two series of twenty-five consecutive cases of perineal prostatectomy, immediately before and immediately after the adoption of the new technic. For the purpose of clearer demonstration, the portion of each chart below 100 F. has been purposely blurred, thus rendering the elevations relatively more conspicuous. In chart 1, representing the temperature curves prior to the adoption of the new technic, the excess of lines above the 100 F. level (as compared with chart 2) is too conspicuous to require further comment.

Chart 3 represents an arithmetical rather than a graphic demonstration that the mercurochrome technic has resulted in a flattening of the average postprostatectomy temperature curve. The two curves represent an accurate portrayal of the average temperature reactions of the two series of twenty-five patients (before and after use of the new technic) during the first postoperative week. The method of computing was merely

Factors Tending to Minimize the Various Prostatectomy Hazards

Hazard	Minimized by
Uremia	Preoperative drainage
Infection	Oral and wound antisepsis; dependent drainage
Immediate hemorrhage	Perineal hemostatic bag; visualization of field and suture ligature
Delayed hemorrhage	Endoscopic fulguration; oral and wound antisepsis
Anesthesia	Sacral block method; avoidance of veins
Abdominal distention	Perineal route
Postoperative "shock"	Perineal route; sacral block anesthesia
Epididymitis	Vasectomy preceding preliminary drainage
Vascular "accidents"	(Prayer)

to average the maximum daily temperature of each of the twenty-five patients. The difference between the two curves is too striking to be ignored. Whereas the average maximum postprostatectomy temperature before the use of the mercurochrome technic was 101.5 F., the average maximum temperature after the institution of the new technic was only 100.2 F. It may be stated that the maximum elevation occurs on the day following the operation.

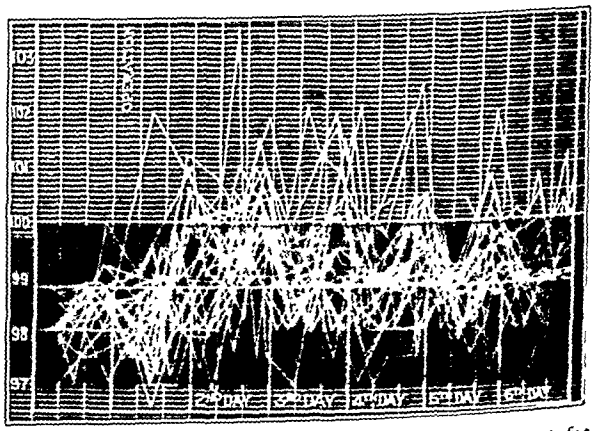

Chart 2.—Temperature curves from the first consecutive twenty-five cases immediately following the adoption of the new mercurochrome technic of wound antisepsis. Note the relatively few rulings below the 99 F. line on the second postoperative day, as contrasted with chart 1.

On the suspicion that the figure 100.2 F., being an average for only twenty-five cases, might not be truly representative, an additional seventy-five cases were observed, bringing the total on which the average was based to 100. The average maximum postprostatectomy temperature was then found to be 100.6 F. rather than 100.2 F. Considering the large number of consecutive cases entering into this tabulation, there can be no question as to the accuracy of the figure.

6. Scott, W. W., and Hill, Justina H.: Presentation of a Preoperative Skin Disinfectant, an Alcohol-Acetone Aqueous Solution of Mercurochrome, J. Urol. **14**: 135 (Aug.) 1925.

7. Harris, Augustus: The Prevention of Infections in Prostatectomy, Am. J. Surg. **14**: 480 (Nov.) 1931.

Without undue enthusiasm, it seems permissible to state that any method of wound antisepsis causing a flattening of the postprostatectomy temperature curve may be regarded as another factor tending to lessen the hazard of prostatectomy. This preliminary report is purely tentative. It is possible that another drug or a variation of the technic here suggested might be far more efficient. It is likewise true that a modification of this method might be applicable in other surgical fields.

IMMEDIATE HEMORRHAGE

A combined hemostatic and drainage bag for perineal prostatectomy was presented in 1927.[8] This bag proved effectual in all but four cases of 741 (99.5 per cent), occurring early in the series, in which emergency suprapubic cystotomy, with suture ligature, became necessary. There was one death directly attributable to hemorrhage. Later in the series it gradually became apparent that additional time and effort devoted to suture-ligature through the perineal incision, at the time of operation, tend to eliminate even this small percentage of hemorrhage. There is no reason why hemostasis need be left to chance, even in the slightest degree. The patient is comfortable and free from pain and there is no necessity for haste. As repeatedly observed through the perineal incision, such arterial bleeding as there may be comes chiefly from tissues underneath the "floor" of the bladder, immediately adjacent to the orifice. The main spurters tend to have an anterior rather than a posterior location and tend to occupy approximately "10 o'clock and 2 o'clock" positions with respect to the vesical orifice. The inflated bag within the bladder being used as a tractor, the bladder neck may be pulled down and the under surface clearly visualized and made accessible. Each portion of the under surface of the bladder neck may be inspected in turn by varying the direction of the traction on the hemostatic bag. An excellent opportunity for visualization and suture-ligation of spurters is thus afforded, after which a "pucker" suture is placed on each side, compressing the relaxed tissues of the two lateral cavities and closing the capsule. This technic practically eliminates the immediate hazard of postprostatectomy hemorrhage.

DELAYED HEMORRHAGE

In 1932 I[9] called attention to an "epidemic" of delayed massive postprostatectomy hemorrhage, occurring from the tenth to the twenty-sixth postprostatectomy day, and suggested an explanation on the basis of a specific infection, including in my paper a method of control consisting of endoscopic aspiration of clots followed by location and fulguration of the bleeding point. The work on which this communication was based preceded the advent of endoscopic prostatic resection by a number of years. The "epidemic" consisted of the amazing number of five cases of delayed massive hemorrhage, in thirteen consecutive cases of prostatectomy, three of these in direct succession, as contrasted with only ten cases of delayed hemorrhage in the preceding 410 cases of prostatectomy, thus permitting no conclusion as to cause other than that the basis was a specific infection. This complication has not been subsequently observed over a period of years, and it may well be that the technic of wound antisepsis described has been a factor in its control. It may also be that one of the newer internal urinary antiseptics (mandelic acid or sulfanilamide) will prove to be of value in this respect. At any rate, it may be conservatively stated that wound antisepsis and endoscopic fulguration have eliminated the real hazard connected with delayed hemorrhage.

ANESTHESIA

The sacral block method, described as applied to perineal prostatectomy in 1922 by Crowell and Thomson,[10] has given complete satisfaction throughout the years and leaves nothing to be desired. There have been no deaths attributable to the anesthesia, no complications and no sequelae. In 1931 I[11] referred to the "infallibility" of the sacral block method, reporting a series of 229 consecutive cases without a single failure in anesthesia. This number has since been increased to 592, still without a failure. Sacral block anesthesia for perineal prostatectomy, properly achieved, is literally infallible. Moreover, adequate time, permitting deliberateness in hemostasis, is afforded. I consider the sacral block method ideal for the specific purpose of perineal prostatectomy.

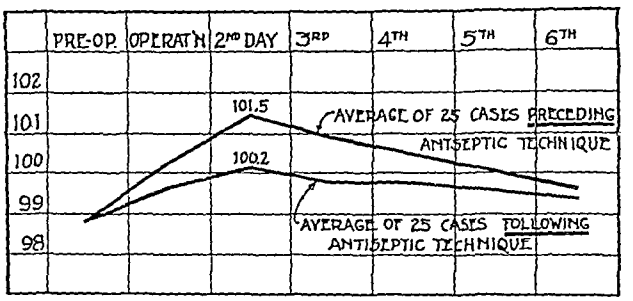

Chart 3.—The average maximum daily elevation of temperature in two series of twenty-five cases of perineal prostatectomy observed before and after the adoption of the mercurochrome technic of wound antisepsis.

OTHER COMPLICATIONS

Abdominal Distention.—This postoperative complication, so frequently the cause of distress and calamity following abdominal or suprapubic incisions, is conspicuously absent with the perineal approach to the prostate. There was only one case in the entire series in which abdominal distention occasioned any real trouble.

Postoperative "Shock."—This term is here loosely employed to designate that condition of semiconsciousness or unconsciousness, together with lowered blood pressure and increased pulse rate, in which the patient is returned to his room after many (if not most) major operations. When the perineal approach to the prostate is used, with sacral block anesthesia, the patient returns to his room in the condition with respect to color and general appearance which preceded the operation. I have frequently observed an elderly patient reading or writing the morning of the operation. Whatever "shock" may be, this condition is conspicuously absent after use of the sacral block method and the perineal approach.

11. Davis, Edwin: Sacral Block Anesthesia in Perineal Prostatectomy: Its Infallibility When Accurately Administered, J. A. M. A. **97**: 1771 (Dec. 12) 1931.

Epididymitis.—Suppurative epididymitis, with chills, fever and sepsis, occurring as late as (or later than) the third postoperative week, was frequently a far more serious matter than the prostatectomy. Routine local infiltration vasectomy, performed at the beginning of preliminary drainage, has practically eliminated epididymitis.

Vascular "Accidents."—Such occurrences as cerebral or coronary thrombosis or pulmonary embolus suddenly interrupting an otherwise smooth convalescence are not to be anticipated, and there is but little to be done by way of prevention. They must be left largely to chance and "prayer." Fortunately, such accidents are rare. It is likely that many cerebral and coronary affairs are coincidental occurrences, wholly unrelated to the operation, and might well have taken place without operation. The same applies to pulmonary embolus. Of thirty-nine cases of pulmonary embolism, demonstrated by autopsy at the University of Nebraska College of Medicine [12] during a recent three year period, there were nine in which the embolus was massive and was considered to be the primary cause of death. Of these nine fatal cases, six were either postpartum or postoperative, while in the remaining three no surgical procedure had been employed.

CONCLUSIONS

Wound antisepsis with mercurochrome during perineal prostatectomy tends to flatten out the postoperative temperature curve and therefore may be presumed to lessen the hazard of infection.

Of the various hazards of perineal prostatectomy, including uremia, infection, hemorrhage (immediate and delayed), complications due to the anesthesia, epididymitis and vascular "accidents," all but the last named are controllable and have been reduced to a negligible minimum.

As determined by a tabulation of the maximum daily postoperative elevations of temperature occurring in 100 consecutive cases of perineal prostatectomy, the average maximum elevation (which occurs on the day following operation) is only 100.6 F.

Clinical Observation and the Experimental Method.—Progress in medicine can be followed historically along two main lines. The first is that traced from Hippocrates through Sydenham; it is the method of observation, and it has given us our descriptions of disease. The capacity of clinical observation to separate and define diseases was greatly enforced by the work of the famous morbid anatomists; the combined observations laid the foundations of modern clinical medicine. Laennec and Skoda, exponents of tested methods of physical examination; Bright, Hodgkin, Corrigan, Addison, who so ably identified and described individual diseases—these names but exemplify that most brilliant period of clinical activity, which was at its height in the earlier years of last century. The second line of progress has been by the experimental method, using this word in its broadest sense; it is exemplified in the physiological field by the work of the physician Harvey and by Claude Bernard; in the bacteriological field by Pasteur and Koch. While the methods of pure observation have long since passed their period of greatest activity, the experimental method continues to display amazing progress and growth.—*Lewis, Sir Thomas:* Research in Medicine and Other Addresses, London, H. K. Lewis & Co., Ltd., 1939.

THE CRITERIA OF EFFECTIVE TREATMENT IN MULTIPLE SCLEROSIS

TRACY J. PUTNAM, M.D.
BOSTON

Multiple sclerosis is often referred to as a rare and mysterious disease. It is probably neither. In the five years from 1931 to 1935 the diagnosis of multiple sclerosis was made for 204 new patients admitted to the Boston City Hospital (approximately 1,800 beds). The corresponding figure for poliomyelitis during the same years was 100, for encephalitis 101 and for proved subacute bacterial endocarditis fifty. In evaluating these statistics it should be noted that no particular effort was being made to bring patients with multiple sclerosis into the hospital for study, as the investigation of multiple sclerosis was being carried out on purely experimental lines and no form of special treatment was being offered. The Boston City Hospital is one of the few hospitals in Boston to which patients with poliomyelitis in the early stage are admitted. While the statistical value of the figure given is open to question, it is obvious that multiple sclerosis presents an important medical and economic problem.

GENERAL PROGNOSIS

The prognosis is usually considered unfavorable. Osler's textbook states that "ultimately, the patient, if not carried off by some intercurrent infection, becomes bedridden," and this perhaps epitomizes the standard opinion. Any treatment which is followed by improvement even in a small proportion of cases is therefore likely to be acclaimed with enthusiasm, especially by physicians with limited experience with the disease. Many different forms of therapy have been proposed and, since excellent results have been claimed for all of them and some are drastic and even dangerous, it seems worth while to make a survey of the results obtained.

STATISTICS

A signal service has been performed by Brickner,[1] who has compiled from the literature the recorded results of many forms of treatment, including the use of antiseptics such as arsenic, antimony, mercury and "germanin," heat and fever, special vaccines and serums, sympathectomy, quinine and even hypnotism, which was followed by success in one case.

From Brickner's table it is possible to prepare statistics on recovery, though rather crude ones. If one excludes all reports of one or two cases and includes only the series in which the actual number of patients treated and the actual number considered improved are definitely given, one arrives at a total of 1,407 cases reported, in 665, or 47.5 per cent, of which the patient was stated to have profited by his treatment. With a few forms of treatment, for example with the use of salicylates, nuclein, liver extract, lecithin given intraspinally and sympathectomy, 100 per cent of improvement was reported, but never in any series larger than eleven cases. Improvement was reported from various forms of fever treatment in 60 per cent of cases, from

Read at the graduate course for the College of Physicians, Boston, April 2, 1938.

roentgen treatment in 58 per cent, from quinine in 49 per cent, from fibrolysin in 48 per cent, from various arsphenamines in 45 per cent and from Purves-Stewart vaccine in 35 per cent. These are the only series large enough to have any pretensions to statistical value.

VARIOUS FORMS OF TREATMENT AT THE NEUROLOGICAL UNIT

It is probable that many of the reports summarized are optimistic. At the Neurological Unit my colleagues and I have had experience with a number of different forms of treatment. This clinic was the first, as far as I know, to utilize a high vitamin diet and injections of liver extract in cases of multiple sclerosis (1928-1930). About ten patients received this treatment; there was no tangible change in the status of any of them. Since then I have seen six patients who are subjectively better with vitamin therapy, but they have not been protected against relapses. We came dangerously near to being enthusiastic over the results of forced spinal drainage, but when we reviewed the twelve cases in which it was used, it was obvious that no permanent improvement had been effected. I have seen ten patients and the brain of an eleventh who have had fever treatment. None of them were subjectively or functionally improved; indeed all but one of the surviving patients considered themselves worse. Arsphenamine, "germanin," typhoid vaccine, quinine, amphetamine (benzedrine) and various other medications have been used in the wards and outpatient department uniformly without success. In eight of thirteen instances in which infections (such as furuncles, infected teeth, sinusitis, cellulitis and cystitis) were found, improvement accompanied the surgical treatment or natural subsidence of the infection.

Even when all these figures are taken together, they are founded on too small a series to be of more than suggestive value. A commission has been appointed by the American Neurological Association to observe and report on a far larger series.

THE COURSE WITHOUT TREATMENT

To evaluate even approximately the benefits of the various forms of therapy so far proposed, it is important to review the natural course of the disease. Unfortunately, few untreated patients have been the objects of such intensive observation as those undergoing treatment.

A survey of the records of 516 patients receiving no systematic treatment has recently been made by von Hoesslin [2] from the hospitals of Munich. He pointed out that the prognosis in multiple sclerosis is by no means as hopeless as many textbooks would lead one to believe. Substantial remissions, so complete that the patients considered themselves practically well, occurred in ninety-two (or over 17 per cent) of his cases. In twelve the remission lasted from fourteen to forty-three years.

The proportion of recovery in a group of 133 patients representing 1,093 "patient years" of the disease followed and analyzed from this point of view by Dr. Madelaine Brown and me [3] gave comparable results. Twenty-seven patients were working (20 per cent), sixty-three were ambulatory (47 per cent), twenty were helpless (15 per cent) and sixteen were dead.

Such statistics are of little value for comparison with those given for the effects of treatment. In attempting to find some possible common basis we determined to study the outcome of the first symptom observed in each case. It is likely that the first symptom is often due to a single lesion, perhaps to the only lesion, and, further, that subsequent lesions are the result of the same process and should have a similar course. In fifty-eight, or 44 per cent, of 133 cases studied the first symptom entirely cleared up, as far as the patient was aware. In an additional thirty-four cases, remission or alleviation of symptoms was reported at some time during the course of the disease. Of 550 separate complaints found in the 133 histories, 274 were reported to have been alleviated spontaneously. The accompanying table gives the incidence of recovery from the various types of symptoms. In general, isolated symptoms were found to be more prone to alleviation than the same symptoms occurring in a group. It appears that those presumably due to small lesions usually disappear promptly, while lesions apparently affecting larger areas are apt to leave more or less permanent residuals or at best to heal so slowly that it is difficult to say when recovery has occurred.

FIG. 1.—"Encephalitic" reaction in an acute extension of an old sclerotic plaque. *Masson stain, high power enlargement.*

The length of time required for recovery is variable. Two patients accurately described a central scotoma lasting only a few hours. About five mentioned attacks of diplopia lasting only a day or two. At the other end of the scale, one patient was bedridden, with dizziness, scotomas, paraplegia and ataxia for six years and then substantially recovered and has led an active life since.

In going over history after history, one receives the unescapable impression of a constant ebb and flow of symptoms. Even in the cases of chronic progressive sclerosis, which make up some 17 per cent of all, the progression is rarely uniform and relentless, like that of a tumor, but is usually broken by quiescent periods.

THE COURSE OF INDIVIDUAL LESIONS

It is further possible to find a correlation between the natural history of various symptoms and the histologic picture of different types of plaques. In practically every case of multiple sclerosis in which a careful examination is made (a survey has been made in this laboratory of about 3,000 slides from some thirty cases) new lesions as well as old ones will be found. The fresh ones are characterized by edema and symptomatic inflammation (fig. 1). In older ones, myelin has become phagocytized and the surviving axis cylinders—almost

invariably found reduced in number if properly examined and sometimes reduced to an insignificant remnant—have regained a normal appearance and presumably normal function.[4] It is common to find evidence of activity about the edges of large old lesions (fig. 2). Thus one finds that a healing process is constantly going on but often intermingled with an intermittent process of acute destruction, exactly as one might expect from a consideration of clinical symptoms.

THE POSSIBLE EFFECT OF TREATMENT ON LESIONS AND SYMPTOMS

From the appearance of the old lesions, as they are seen in case after case, there appears to be little hope that any form of treatment will cause axis cylinders to grow again, myelin to reform or glial scars to resolve. The damage is done; the tissue is sometimes as devoid of parenchymal elements as infarcts of comparable size.

It is difficult to escape the conviction that the same is true of the acute lesions also if one makes a detailed study of the steps of the reaction. The damage to axis cylinders, which are after all the essential functioning elements, is already extensive in the earliest plaques one can find. Figure 3 shows one probably not over

Principal Symptoms in 133 Cases of Multiple Sclerosis (Putnam and Brown [3])

	As First Symptom		As Subsequent Symptom	
	Total	Alleviated	Total	Alleviated
Paraplegia	19	9	70	22
Ataxia, tremor	23	10	44	15
Monoplegia	24	13	33	18
Scotoma	20	16	32	20
Numbness of one extremity	20	15	26	13
Bladder symptoms	6	4	30	15
Diplopia	18	12	24	14
Numbness of both legs	7	5	19	15
Speech defect	2	2	22	4
Mental deterioration	2	0	16	1
Hemiparesis	6	3	11	5
Pain (radicular)	1	0	10	5
Hemianesthesia	5	4	4	4

a week old, as determined by the history of the case and the method of timing histologic reactions worked out by Alexander and Newbill.[5] There is more apparent damage to axis cylinders than in many older plaques. From this stage on, barring infections elsewhere or poor nutrition, some healing is inevitable and the duration and extent of the lesion determined.

If the lesions run their course irrespective of treatment, it is no wonder that the symptoms they produce should do the same. If one assumes, as seems reasonable, that patients usually seek a new form of treatment when a new lesion occurs and that 44 per cent of fresh lesions are capable of a complete functional recovery, it is perhaps not remarkable that 47.5 per cent of patients given treatment of any kind have been reported to show some improvement. Sometimes the benefit reported to follow the therapeutic experiments previously summarized has been slight or wholly subjective; sometimes it followed the treatment by a year or more, and in many instances it was obviously temporary. Both pathologic data and statistical studies should make one cautious in accepting symptomatic improvement as evidence of the success of specific treatment. The criterion of successful therapy should be in the prevention of relapses.

POSSIBLE CAUSES OF UNDUE OPTIMISM WITH REGARD TO TREATMENT

In making the criticism that optimism is often unfounded, it is far from my purpose to suggest any lack of sincerity on the part of the sponsors of new methods of therapy. It is a callous man who does not feel moved to make the attempt to alleviate the miserable condition of patients incapacitated by multiple sclerosis or to avert the disaster which hangs over those mildly afflicted. As long as doctors are ignorant of the nature of the underlying process, it is only natural that they should turn to treatments which are effective for other conditions with similar symptoms, such as neurosyphilis. The textbook picture of the course of multiple sclerosis is founded on late chronic involvement, but with modern methods of diagnosis, earlier and more benign forms are recognized and the physician is encouraged if the downward progress is found to be slow. Few forms of treatment are given to bedridden patients, and statistics tend to become artificially loaded with cases of fresh, remittent sclerosis. This is clearly shown in the present series; of thirty-eight patients seen in office practice, sixteen were working, thirty-six were ambulatory and none have died; while of ninety-five patients seen in the wards during approximately the same period, only twenty-seven were ambulatory, eighteen were helpless and seventeen have died.

There is apt to be a complementary tendency to fallacy on the patient's side. The invalid who is confined to a hospital for chronic diseases does not shop for treatment; the ambulant sufferer threatened with incapacity is likely to. The euphoria of patients with multiple sclerosis is well recognized. I remember one who was brought in a wheel chair week after week for ultraviolet irradiation over a period of years until he became bedridden, each time stating for the record that he was better. Encouragement definitely alleviates the disease, if only temporarily, and it is a feature which is common to all treatments. Even though the degree of recovery is definitely limited by the destruction of axons, the doctor is not free from the responsibility of promoting healing. If he were dealing with a fracture or a wound on the surface of the body, he would insist on mechanical rest of the part, avoidance of infection, adequate measures against any existing anemia or dietary deficiency and, as far as possible, protection against worry.

In addition, the art of symptomatic treatment is worth cultivating. Some of the measures which are useful in relieving specific symptoms have been discussed in another publication.[6] Sometimes placebos have to be administered. Liver extract and bromides are well adapted to this purpose.

THE PREVENTION OF FRESH LESIONS

General Measures.—If lesions tend to appear suddenly in an acute state or to grow by acute extensions, the principal effort should be devoted to preventing their appearance. One way of doing this is to avoid the external circumstances which appear to precipitate relapses. These excitants are ordinarily stated to be injuries, infections, exposure to cold and pregnancy. Von Hoesslin's [2] critical study bears out the usual impression. Among the 516 cases which he reports, the disease in 132 was apparently precipitated or aggravated by exogenous factors. The presumed cause was

6. Putnam, T. J.: The Diagnosis of Multiple Sclerosis and the Outlook for Treatment, M. Clin. North America 21: 577-593 (March) 1937.

injury in fifty-two cases, pregnancy and delivery in twenty-three, infection in twenty-two, extreme overexertion in fifteen, chilling in ten, emotion and excitement in eight and poisoning in two. The statistics of the Neurological Unit are in general agreement.

For patients with multiple sclerosis, such disturbances are to be avoided if possible. Obviously it will seldom be possible to insure against all of them.

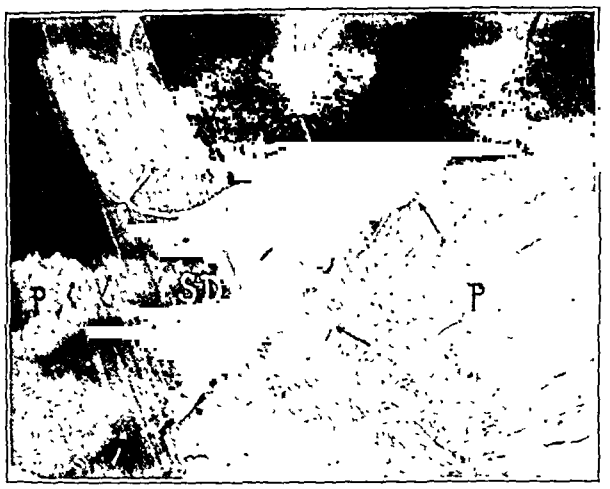

Fig. 2.—Marginal extensions (arrows) above two old gliosed plaques (*P, P*) in the cerebral white matter. A band of fresh secondary degeneration (*SD*) is in progress between them. Mallory stain, × 5.

Are Specific Measures for Preventing the Occurrence of Fresh Lesions Conceivable? It is seldom possible to devise a successful treatment without a knowledge of the fundamental mechanism of the disease. For this reason the first eight years of the work carried out under the Harvard Multiple Sclerosis Fund consisted of a systematic and critical review of the theories of pathogenesis of the disease and an attempt to compare the development of its lesions with pathologic processes of known origin.[7] When the hypothesis of an origin in a thrombosis of small vessels in the nervous system began to intrude itself on the unwilling minds of the investigators, an elaborate series of studies was planned to test the theory from many angles of approach. These included the production of lesions in animals by experimental venous obstruction and by intravenous injection of coagulants, a search for evidences of vascular obstruction in plaques and a comparison of plaques with other pathologic processes, a search for the specific "silver cells" of multiple sclerosis in thrombotic lesions and a comparison of the mineral content of plaques with that of infarctions. All these investigations confirmed the original hypothesis. It is of interest that McKhann,[8] working in the field of the pathology of the clotting mechanism, has come to the conclusion that some such disease should exist.

Can such a conception be used for therapeutic purposes? In animal experiments it was found possible to protect against many times the usually fatal dose of a coagulant such as lung extract by preliminary administration of any one of a number of anticoagulants, such as cysteine, heparin, "germanin" and certain dyes. A cautious trial of certain of these agents is under way with a group of patients selected as having the disease in a remittent stage with fairly regular relapses. It is certainly possible to give some of these agents over a long period without injury to the patient and to prolong the clotting time of the blood by their administration.[9] They have no immediate effect on established symptoms, and those at present available cannot be depended on to prevent relapses. Whether or not they produce a significant decrease in the incidence of exacerbations and whether more efficient measures may be found by systematic search remains to be seen.

SUMMARY

1. Multiple sclerosis is characterized by a tendency to spontaneous remissions of greater or less degree. Some definite improvement at some time occurred in 69 per cent or more of 133 cases studied. Complete disappearance of the first symptom was reported by 44 per cent of the patients. The incidence of remissions was far higher for ambulatory patients seen in office practice than for ward patients.

2. A survey of the reported results of the more widely used forms of treatment shows that the proportion of patients improved varied from 35 to 60 per cent, with an average of 47.5 per cent, in a total of 1,407 cases analyzed.

3. The effects of the more popular types of therapy in the present series have not been encouraging.

4. On the basis of the statistical evidence and also of the microscopic appearance of plaques studied at various stages of development, there is good reason for believing that the maximum extent of the future recovery from acute lesions is determined at the time the lesions are formed and that reparative processes run their course irrespective of treatment (aside from attention to hygiene and nutrition).

5. The criterion of the success of any treatment of multiple sclerosis should probably be the prevention of relapses.

PELVIRADIOGRAPHY AND CLINICAL PELVIMETRY

COMPARATIVE VALUES IN THE PROGNOSIS OF THE OUTCOME OF LABOR

EMANUEL M. RAPPAPORT, M.D.
AND
SAMUEL J. SCADRON, M.D.
NEW YORK

Pelvimetry is an important phase of modern obstetrics, yet the subject remains somewhat confusing and lacking in precision. The external pelvic measurements are at best inadequate as a true index of pelvic types. The internal measurements, however, offer certain accurate data covering the pelvic inlet, the contour, the sweep of the subpubic arch and the outlet. X-ray examination was originally employed for the purpose of attesting fetal presence, multiple fetus and fetal deformities. During the last fifteen years, as a result of the investigations of Thoms, Chambers, Jarcho, Spalding, Ball, Hirsch and others, several methods of x-ray pelvimetry

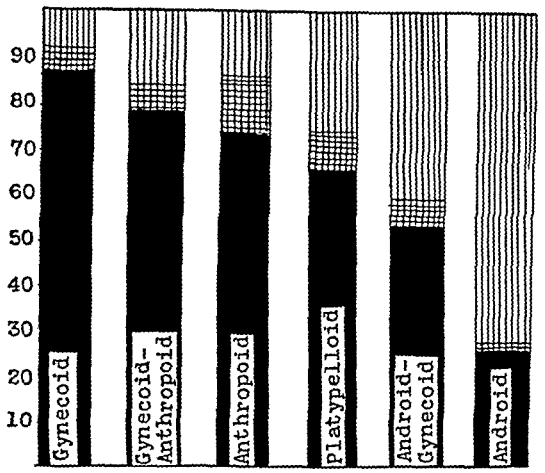

Fig. 1.—Types of pelvis and types of delivery. The black areas indicate spontaneous deliveries, the crosshatching elective forceps deliveries and the parallel lines instrumental deliveries.

have been introduced. These investigations culminated in the classic contribution of Caldwell and Moloy,[1] who have provided, with the use of roentgen rays, a simple yet practical and accurate classification of the various pelvic types and have augmented our knowledge of the mechanism of labor.

This study covers a series of 350 patients, including 315 ward and thirty-five private patients. The x-ray examination was made ten days prior to the calculated date of labor. In instances of miscalculation, when labor was delayed by several weeks, x-ray examination was repeated at term. In the classification of the various types of pelves, such factors as size of inlet, relationship between head and inlet, sacrosciatic notch, inclination of sacrum and lateral bore, sacral promontory, subpubic angle, shape of arch, length of rami and side walls of the pelvis were taken into consideration. The classification adopted was that of Caldwell and Moloy.

From the Maternity Division of Beth Israel Hospital.
Read before the Section of Obstetrics and Gynecology, New York Academy of Medicine, Dec. 28, 1937.
Drs. I. Seth Hirsch and Myron A. Schwartzchild aided with the roentgenologic aspects of this study. The technic used herein was that which they have described.

1. Caldwell, W. E., and Moloy, H. C.: Am. J. Obst. & Gynec. 26: 479 (Oct.) 1933.

In this series the percentages of the various major pelvic types closely approximate the original figures of Caldwell, Moloy and D'Esopo,[2] with the exception of the platypelloid type. This type, considered a rarity by the original observers, was found in appreciable numbers in our series. This may be explained on the basis of racial differences, since the series consisted entirely of patients of the Jewish race, wherein females of the hyposthenic and pyknic type are frequently encountered.

TYPES OF PELVIS

Gynecoid.—The gynecoid pelvis is the type most frequently encountered in any series; it occurred in 158 of our 350 cases (fig. 1). The highest incidence of spontaneous deliveries with the major types occurred with this type. Of the 158 patients 136, or 84 per cent, were delivered spontaneously; and of the 16 per cent of operative deliveries nearly 60 per cent were low forceps and one half of these were elective. Two of the four cesarean sections in this group were performed because of extrapelvic conditions. Contraction of the inlet was uncommon and dystocia, when it occurred, developed at or below the level of the spines.

Anthropoid.—The anthropoid type was next in frequency, with fifty-two cases. Easy delivery was the rule in the majority; forty, or 77 per cent, of the patients were delivered spontaneously. Half of the operative deliveries were elective low forceps deliveries. The only cesarean section performed in this group was of a 38 year old woman with a history of six previous spontaneous miscarriages.

The fetal head frequently engaged in a posterior position, but spontaneous rotation (anteriorly) occurred in the majority of cases. While we agree with Thoms[3] that a persistent occipitoposterior position is more frequent with the anthropoid than with other types, the incidence in our series was low, this complication being noted on only seven occasions. There were three deliveries by forceps in the occipitoposterior position; two of the fetuses were rotated by forceps and two delivered spontaneously with face to pubis. A probable cause of this favorable outcome is that the anthropoid pelvis has actually larger dimensions than any other type, both at inlet and outlet. The majority of the justo major pelves in our series were anthropoid, which is commensurate with the physique of women of this type.

Android.—Forty-four women in our series showed the true android type of pelvis and twenty-three the mixed android type (i. e., with android posterior segments and gynecoid forepelvis). The android type of pelvis entails the most difficult deliveries. Spontaneous delivery in this group was the exception rather than the rule. In only sixteen of forty-four parturient women (36.4 per cent) did labor terminate so favorably. Difficult midforceps extraction was required in eleven cases (25 per cent). There were twelve cases (27 per cent) of cesarean section and five additional cases in which this operation was evidently indicated, labor terminating either in craniotomy, spontaneous stillbirth after protracted labor, or version after so long a time had elapsed after rupture of the membranes that cesarean section would have been precarious. Thus the incidence of delivery by the abdominal route would have been 39 per

2. Caldwell, W. E.; Moloy, H. C., and D'Esopo, D. A.: Am. J. Obst. & Gynec. 28: 482 (Oct.) 1934.
3. Thoms, Herbert: Surg., Gynec. & Obst. 56: 97 (Jan.) 1933.

cent. Unlike the other pelvic types, dystocia started at the inlet, with progressive difficulty at the midpelvis and outlet.

Hence it is of utmost importance that the obstetrician recognize clinically the android pelvis, for this type presents a definite hazard to both mother and fetus. In less than one third of the cases of this type in our series did labor terminate spontaneously with a living baby.

With the mixed types the percentage of operative deliveries declined (39.1 per cent), but such deliveries were nevertheless more frequent than with the other major types, except the true android. Thus, although the average inlet dimensions were barely greater than those of the true android pelvis, the presence of the wide anterior segment increased considerably the chances for engagement of the fetal head. However, had cesarean section been resorted to in the four cases in which delivery terminated in either craniotomy or fetal death after prolonged labor, the incidence of this operation would have been 26 per cent rather than 8.7 per cent.

The troublesome dystocia dystrophica syndrome, described by Cornell [4] and Greenhill,[5] is not associated exclusively with any particular type of pelvis as far as we have been able to determine. Thoms said that this syndrome is found most commonly with the anthropoid type, but we have encountered it most frequently with the android. The physique of the patient described by Cornell typifies the android rather than the anthropoid type.

Platypelloid.—As has been noted, the platypelloid type of pelvis occurred more frequently in our series than is usually the case; there were twelve cases of true platypelloid pelvis and nine cases of mixed type. Delivery was effected easily in sixteen of these cases. In three cesarean section was required, and in two version was successful after the fetal head had failed to engage. As a rule, in this type of pelvis the narrow anteroposterior diameter is amply compensated for by a broadened transverse diameter. Furthermore, obstruction to the fetal head is usually encountered only at the inlet and, once this is traversed, uneventful delivery may be reasonably expected.

FURTHER USES OF X-RAY PELVIMETRY

The fact that x-ray pelvimetry makes it possible to determine the type of pelvis in each case, which, as has been shown, is of practical importance in determining the probable course of labor, is not its only value. It gives more accurate measurements of the pelvic diameters, especially of the inlet, than clinical methods, as has been demonstrated in our series. It also discloses the position and relationship of the important pelvic landmarks, especially when the stereoscopic method is employed—factors of definite significance to the obstetrician.

Measurements and Size of Inlet.—The x-ray measurements of the pelvic inlet appear to be consistently greater than those clinically determined. Not infrequently the true conjugate obtained by x-ray examination is the same measurement recorded by the clinician as the diagonal conjugate. This disparity arises from errors in the clinical methods, especially in deducting 1.5 to 2 cm. from the diagonal conjugate, particularly when the inclination of the symphysis is toward the sacrum. Again, when false promontories exist or when the sacrum slopes forward rather than backward, lower levels than the true promontory are palpated and smaller measurements are obtained than actually exist (fig. 2). Thus, contractions of the anteroposterior diameter are diagnosed erroneously.

Stander [6] designated as a borderline pelvis one whose conjugata vera measured between 7.5 and 9 cm. and stated that "in more than one half of such cases, spontaneous labor can be looked for; where the conjugata vera falls between 9 and 10 cm. spontaneous labor is the rule." This, however, is contrary to our experience. There were twenty-three pelves in our series with the true conjugata (or anteroposterior diameter) varying between 8 and 9.9 cm. In the twenty cases in which this diameter varied from 9 to 9.9 cm. the following results were obtained: spontaneous delivery in four, or 20 per cent (sum of the anteroposterior and transverse diameters, 23.3 cm.); difficult forceps delivery in three, or 15 per cent; craniotomy in two, or 10 per cent (sum of the anteroposterior and transverse diameters, 21.6 cm.); version in one, or 5 per cent, and cesarean section in ten, or 50 per cent. In the remaining three cases, in which the conjugata vera measured 8 or 8.9 cm., cesarean section was performed.

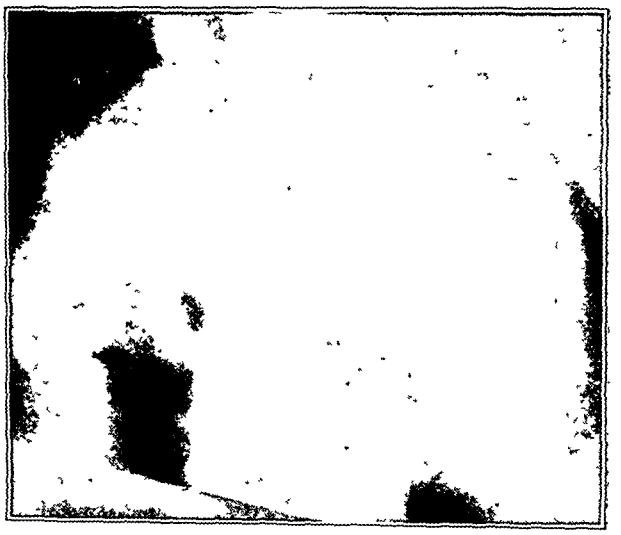

Fig 2.—The false promontory shows that a lower level than the true promontory may be palpated

These results in our series show therefore that any pelvis with a conjugata vera of less than 10 cm., as determined by x-ray examination, is to be considered as contracted. The transverse diameter of the inlet, however, deserves special consideration, for a broadening of the pelvis transversely will compensate for a narrowing of the anteroposterior diameter. While no hard and fast rules can be drawn, it would seem from our series that, when the sum of the conjugate and transverse diameters of the inlet equals or exceeds 24 cm., engagement of a fetal head of average size will almost invariably occur. Hence, in the four cases cited in which spontaneous delivery occurred despite a contracted anteroposterior diameter, the sum of the inlet diameters was 23.3 cm. and the average fetal weight was 7 pounds. In the nineteen cases in which a cesarean

4 Cornell, E. L. Surg., Gynec. & Obst. 53:707 (Nov.) 1931.
5 Greenhill, J. P. S. Clin. North America 4:811 (June) 1924; Internat. Clin. 4:171 (Dec.) 1925.
6 Stander, H. J. Williams Obstetrics, ed. 7, New York, D. Appleton-Century Company, Inc., 1936.

or instrumental delivery was performed, the sum of the inlet diameters averaged 21.6 cm., with an average fetal weight of 6 pounds 9 ounces. In eighteen cases of android pelvis in our series in which this figure was less than 22 cm. regardless of the length of the conjugata vera, not a single delivery by vagina of a living baby occurred.

Sacrosciatic Notch.—The importance of the sacrosciatic notch as a reflection of contraction of the poste-

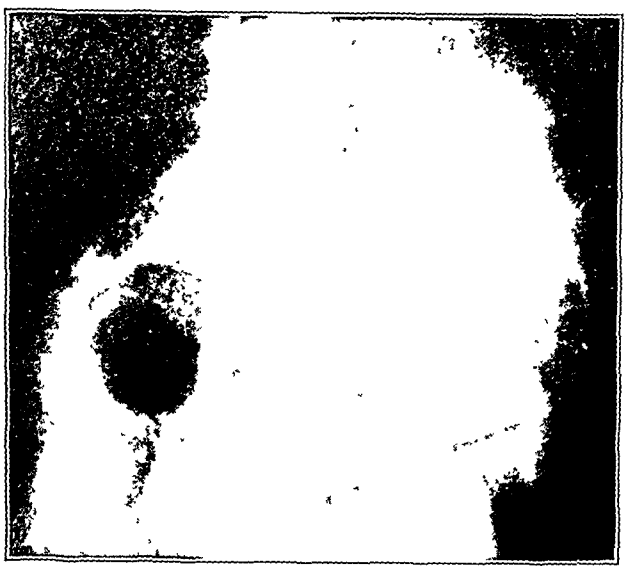

Fig. 3.—The pelvic inclination of the superior strait is increased and the sacrum flares backward.

rior segment has been adequately stressed by Caldwell and Moloy. Suffice it to say that the narrow notch is almost invariably found in the android pelvis, and when it is present careful attention must be directed to the anterior segment and subpubic arch before predicting successful delivery.

Ischial Spines.—The presence of excessively prominent spines by itself will rarely give rise to dystocia. Only in associating with convergent side walls and lateral bore do these projections become factors in obstructing the passage of the head. With the anthropoid pelvis, however, because of the narrowing of the transverse diameter, dystocia due to flaring spines may occur.

Inclination of Sacrum and Lateral Bore.—The sacral tilt and lateral bore are visualized on the lateral view of the pelvis. The tilt of the sacrum shows considerable variation even in the normal pelvis, where it is usually found directed moderately backward. A forward tilt is encountered infrequently. It is most often found in the android type of pelvis. A sacrum directed backward, almost parallel to the horizon, is more common and may be encountered in all type of pelves. It, however, was most frequently associated with the platypelloid and android varieties. This backward flare of the sacrum may be detected clinically by external examination. It occurs usually in the short stocky woman with exaggerated lumbar lordosis. When the pelvic inclination (plane of the superior strait) is increased in association with a sacrum flaring backward and a straight or a convergent lateral bore, labor is usually complicated, and it is with pelves of this type, usually android, that we have noted a high incidence of both difficult delivery and cesarean section (fig. 3).

In most pelves with a normal or somewhat exaggerated backward slope of the sacrum the lateral bore becomes divergent, affording a more spacious midpelvis. Again, in the less common variety where the sacrum is directed relatively forward in the pelvis, both the midpelvis and the outlet are encroached on, and frequently this results in a midpelvic arrest. This is a common cause of midpelvic arrest in the android pelvis (25 per cent of this type occurred in our series).

Fortunately in the anthropoid type, where the transverse diameter at midpelvis is frequently narrower, even than at the inlet, the sacrum usually tilts backward and has a curve more accentuated than normal; this often results in a divergent lateral bore. This affords room for spontaneous rotation of a well flexed head in the posterior half of the pelvis. The mechanism was observed in several pelves of this type, and it was ascribed to a roomy posterior segment below the inlet. This pelvic spaciousness was due to a wide sacrosciatic notch associated with exaggerated posterior tilt and curvature of the sacrum.

Promontory.—A high promontory is usually the accompaniment of a six piece sacrum and is seen most frequently in the anthropoid pelvis; it is less common in the android and least common in the gynecoid. Little importance can be attached to the height of the promontory, except that a high promontory is most prevalent in the male type of pelvis.

Side Walls.—The side walls of the pelvis are visualized both in the outlet film and in the stereoscopic view, although a better knowledge of the degree of slope is obtained from the former. Normally the lateral walls of the pelvis slope gently inward with the maximum

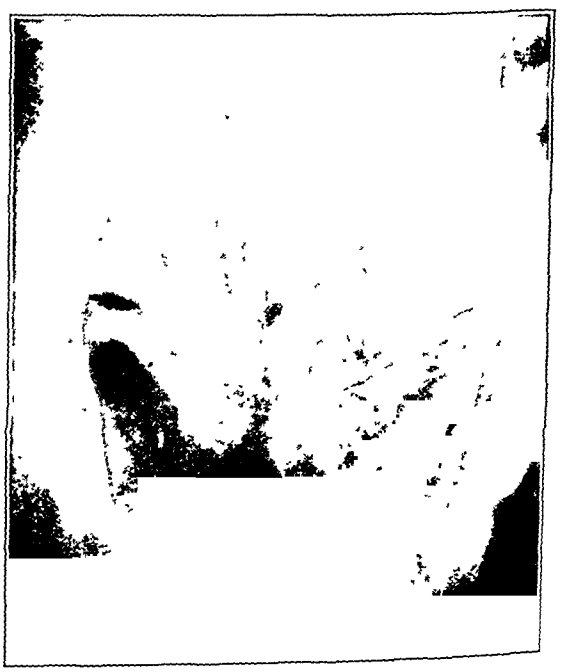

Fig. 4.—An android pelvis with convergent side walls.

inclination at the ischial spines, making for a slight convergence of the pelvic side walls and diminishing the transverse diameter of the midpelvis. Occasionally the walls are straight or parallel to each other. Varying degrees of midpelvic contraction due to convergence of the side walls are encountered. In the anthropoid

pelvis this convergence may account for the frequency of persistent occipitoposterior position, which has been stressed by Thoms. The relatively narrowed transverse diameter of the inlet is encroached on by the converging lateral walls, preventing the head from rotating and necessitating delivery without rotation to an anterior position. In the android pelvis there is a marked tendency to excessive convergence of the side walls as they approach the spines, resulting in a true funnel-shaped birth canal. Failure of the fetal head to rotate spontaneously at lower levels may be due to the soft tissues. Not infrequently in primiparas a difficult delivery may occur as the result of an arrest of the fetal head in a transverse position below the spines, where no bony obstruction can be demonstrated, while subsequent deliveries are rapid (fig. 4).

delivery. Fortunately, however, such minor true relative contractions at the outlet give rise to no great problem in delivery.

Relationship Between Head and Inlet.—One of the most important criteria in prognosticating the outcome of labor appears to be the relationship between the fetal head and the pelvic inlet as viewed stereoscopically. This may be considered to be of even greater value than the pelvic measurements, particularly with borderline and relatively contracted pelves. The information derived from the stereoscopic view, however, must be combined with clinical and other x-ray criteria.

RESULTS

The accompanying tables present a summary of our observations on the 350 parturient women who were

TABLE 1.—*Type of Delivery According to Pelvic Type*

† Cesarean section performed because of six previous spontaneous miscarriages

Subpubic Angle, Shape of Arch and Length of Rami—Narrowing of the subpubic angle, while commonest in the android type, is found in all pelvic types but least frequently in the anthropoid and platypelloid varieties. In our experience clinical examination is somewhat more accurate in distinguishing moderate contractions of the outlet than x-ray examination, for by the latter method "narrow outlet" is diagnosed too frequently. Unfortunately our technic does not permit accurate measurements of the biischial diameter or the length of the rami, the latter playing an important part in outlet contractions. While marked contractions are easily detected radiographically, minor contractions frequently are overlooked. Furthermore, when the fetus is large the outlet which appears ample on x-ray examination proves insufficiently roomy for spontaneous

examined roentgenographically near or at term and whose progress in labor was closely studied. Table 1 shows pelvic types, percentage of spontaneous and operative deliveries (with correction for conditions other than dystocia requiring operative delivery) and average inlet measurements.

A more detailed analysis of the mode of operative delivery required with the various pelvic types is presented in table 2.

In comparing the accuracy of the clinical and the radiologic prognosis of the outcome of labor in our series, we divided the diagnoses into four general groups and compared these with the clinical results, as shown in table 3.

A. *Clinical and X-Ray Diagnosis, Ample Pelvis.*—In this large group, comprising nearly two thirds of

the entire series, only four pelves proved to be contracted that were not so diagnosed either clinically or by x-ray examination, and in these cases the contractions were slight, so that delivery was easily effected by forceps, with no detriment to mother or fetus. Hence, when clinical and x-ray diagnosis pointed to a normal delivery, the error in a large series proved almost negligible.

B. *Clinical Diagnosis, Contracted Pelvis; X-Ray Diagnosis, Ample Pelvis.*—It is in this particular group that we believe that pelviradiography has its greatest value, namely when the pelvis has been judged contracted on the basis of the usual methods of external and internal pelvimetry. We have stated that the clinical measurements are almost invariably smaller than those obtained stereoscopically and have cited the reasons for this disparity. Of the thirty cases in which the x-ray examination showed an ample pelvis and the pelvis was considered contracted by the clinician, the clinician was correct in only 16.6 per cent. In six cases in which the possibility of cesarean section was considered on clinical grounds, the radiographic prediction of spontaneous delivery was later substantiated. Of the five pelves correctly diagnosed by the clinician as contracted and erroneously labeled ample by the roentgenologist, only one was sufficiently contracted to give rise to difficulty in delivery; the remaining four were only moderately contracted at the outlet.

TABLE 3.—*Diagnosis Versus Clinical Results*

Diagnosis	No. of Cases	Proved Ample	Proved Contracted	Percentage Correct
A. Clinic: ample X-ray: ample	257	253	4	Clinic: 98.4 X-ray: 98.4
B. Clinic: contracted X-ray: ample	30	25	5	Clinic: 16.6 X-ray: 83.4
C. Clinic: ample X-ray: contracted	19	5	14	Clinic: 26.3 X-ray: 73.7
D. Clinic: contracted X-ray: contracted	44	5	39	Clinic: 88.6 X-ray: 88.6

C. *Clinical Diagnosis, Ample Pelvis; X-Ray Diagnosis, Contracted Pelvis.*—In this group, again, x-ray examination proved somewhat the more accurate. In the five cases in which difficulty in delivery was predicted by x-ray examination despite ample clinical measurements, spontaneous delivery occurred. However, the contraction diagnosed roentgenologically in each case was at the outlet, and in not a single instance was abdominal section advised. In one case a test of labor was advised, resulting in spontaneous delivery, but only after labor had progressed for fifty-seven hours. On the other hand, fourteen pelves considered ample clinically proved to be contracted according to x-ray examination: In five cases elective cesarean section was considered the only means of insuring a living baby, despite clinical opinion to the contrary. The results were three spontaneous deliveries of stillborn infants after protracted labor, one craniotomy and one cesarean section after a test of labor. In the remaining nine cases, contractions of a less serious nature were correctly diagnosed by x-ray examination and the infants delivered from below.

D. *Clinical and X-Ray Diagnosis, Contracted Pelvis.*—Of forty-four patients for whom dystocia was predicted both clinically and roentgenologically, five were delivered spontaneously and thirty-nine required operative or instrumental aid, the correct diagnosis being made for 88.6 per cent. However, this is too flattering to both the clinician and the obstetric roentgenologist, for it does not represent their prediction as to the outcome of labor, which, with the contracted pelvis, is of paramount importance. Thus a diagnosis of "contracted pelvis" carried little meaning unless the observer specified whether the contraction militated against delivery of a living baby through the natural channel. In seventeen cases, as a result of both clinical and x-ray examination, elective cesarean section was performed, with no resultant fetal or maternal mortality. In ten other cases, in which cesarean section was indicated on the basis of x-ray evidence and in which forceps delivery was suggested on the basis of clinical evidence, the labor resulted in two craniotomies, two midforceps deliveries with living babies, two difficult forceps deliveries with stillbirths, one cesarean section after adequate test of labor, one midforceps delivery with traumatic separation of the symphysis (living baby), one difficult midforceps delivery with postpartum hemorrhage and sepsis (duration of labor thirty-six hours, living baby) and one version after twenty-four hours of labor (head floating, laceration of the cervix, severe postpartum hemorrhage, living baby).

COMMENT

A clinical diagnosis of contracted pelvis was made far too often. While pessimistic opinions were rendered clinically as to the prognosis of labor in seventy-four cases, only 59.1 per cent of these opinions proved correct, as compared with 84.1 per cent of accuracy for x-ray prognosis. It was further found that both clinical and radiographic methods reached a high degree of accuracy in the diagnosis of "ample" pelves. For the entire series the x-ray prognosis was correct in 94.6 per cent of cases and the clinical in 86.3 per cent. This is expressed graphically in table 4.

In comparing the accuracy of clinical and x-ray predictions of the outcome of labor and in deciding the method of delivery, we received opinions from both the staff and the courtesy obstetricians. The greatest accuracy was attained when the two methods (clinical and x-ray) were combined, i. e. when obstetricians familiar with pelviradiography examined the films as well as the patient. We do not believe that the roentgenologist alone can render a more accurate opinion (except academically) than the experienced obstetrician. For the inexperienced clinician, however, the x-ray record should be a valuable guide. Moreover, both the obstetrician and the roentgenologist must know their limitations. We do not mean to imply that pelviradiography will prove an absolute panacea for clinical doubts, nor does it approach mechanical accuracy. It does, however, lend a more suitable means of comparing the adaptability of the fetal head to the pelvis

TABLE 4.—*Accuracy of Diagnosis*

	Diagnosis	No. of Cases	Proved Contracted	Proved Ample	Percentage Correct
Clinic	Contracted	74	44	30	59.1
X-ray	Contracted	63	53	10	84.1
Clinic	Ample	276	18	258	93.5
X-ray	Ample	287	9	278	97.0

than has hitherto been available. Furthermore, with exact knowledge of pelvic types, the x-ray method provides a scientific approach to the problem of the type of forceps most suitable for the individual case, including its mode of application. Similarly it furnishes an index to the optimum pelvic level for rotation should the maneuver be necessary.

Heretofore, when the physician was equipped with a clinical knowledge of pelvic types, the selection and the application of forceps was a matter of personal equation based on trial and error. Many attempts at rotation have failed in the case of the anthropoid pelvis. In the anthropoid pelvis with a relative contraction of the transverse diameter, the head engages in the long anteroposterior diameter. Attempts at rotation are dangerous to both mother and child. With the aid of the stereoscope such futile and dangerous trials may be avoided, dislodgment and rotation above the contraction plane or a delivery in the posterior position being substituted. The Kielland forceps is most suitable for this type of rotation and delivery.

With the platypelloid pelvis, corresponding to the simple flat pelvis, rotation is inadvisable for a transverse arrest. Here delivery is facilitated first by traction in the transverse plane and then by rotation at the outlet. The Barton forceps is most suitable, especially in the presence of an asynclitism.

For a traverse arrest in the android or android-gynecoid pelvis, rotation is best accomplished by the use of the Kielland forceps.

We feel that clinical experience without the use of pelviradiography has the advantage over the use of x-ray interpretation alone, and it is of paramount importance for the obstetrician of the future to develop himself clinically rather than to rely solely on x-ray methods. Finally, we believe that the greatest acumen in determining the relative size of passage and passenger and in selecting the appropriate operative procedure is best obtained when the experienced obstetrician combines his clinical knowledge with pelviradiography.

CONCLUSIONS

The various pelvic types, as demonstrated by x-ray pelvimetry, are of definite significance in determining the course of labor.

X-ray measurements were consistently greater than those obtained clinically.

The relationship between fetal head and inlet as seen stereoscopically is one of the most important criteria in x-ray prognosis of the outcome of labor, particularly with the borderline and relatively contracted pelvis.

When clinical and radiologic opinions agree that a pelvis is ample for the fetus, normal delivery may be expected in the vast majority of cases.

X-ray pelvimetry provides an excellent "negative test" for pelves diagnosed clinically as contracted. Hence every woman suspected of pelvic contraction should receive the benefit of a pelvic stereogram.

Pelviradiography has its greatest value in determining inlet contractions but is less efficacious in predicting dystocia below the ischial spines.

The greatest accuracy was attained when both clinical and x-ray observations were correlated.

Pelviradiography is an obstetric study rather than a radiologic problem, and interpretation of films is preferably rendered by the obstetrician trained in roentgenology.

LEIOMYOSARCOMA OF THE DUODENUM

REPORT OF A CASE AND REVIEW OF THE LITERATURE

J. C. FOSHEE, M.D.
AND
W. P. L. McBRIDE, M.D.
GRAND RAPIDS, MICH.

The duodenum is the seat of tumors of mesoblastic origin in rare instances. Leiomyosarcoma of the duodenum is of interest because of its extreme rarity and because of its similar behavior in every case reported, as will be shown. Only five cases have been reported to date. We record the sixth case and give a brief review of the literature.

Our search reveals only three articles that are confined to the subject of leiomyosarcoma of the duodenum. The articles are in the main case reports. A comparative study of these cases has not been made heretofore. Perhaps this is because the series is so small.

In this paper we shall not attempt to discuss leiomyosarcoma of the gastrointestinal tract except as it pertains to cases involving the duodenum. Raiford,[1] in his treatise on tumors of the small intestine, has dealt with the subject in such a thorough fashion that little can be added. Mumey's[2] article on sarcoma of the small intestine deals exceptionally well with the several types of sarcoma to be found in the region of the small intestine. Confusion is brought about in some of the past articles by the authors including lymphosarcoma and by covering the various divisions of the small intestine instead of confining the discussion to that of the duodenum. Lymphosarcomas do not arise from the same tissue as do leiomyosarcomas. They grow differently, producing a different pathologic picture and different symptoms, as we shall show. A careful analysis of the cases of leiomyosarcoma confined strictly to the duodenum will give information of sufficient interest to warrant our complete study of the subject.

REPORT OF CASES IN THE LITERATURE

The first case report was by von Salis[3] in 1920. His patient was a man aged 40 who had had symptoms of peptic ulcer for seven years. There had previously been an operation performed for the gastric symptoms. Three months before his admission with leiomyosarcoma he had fever and had felt an abdominal mass. At operation a lobulated tumor the size of a baby's head was found arising from the muscular wall of the third portion of the duodenum in its distal part. A fistula to the lumen of the bowel and an abscess were present. The tumor did not produce obstruction or dilatation of the duodenum. The patient lived four months after operation. The tumor was found to be a leiomyosarcoma at autopsy. Diagnosis was not made previous to the operation, and the type of operation performed was not described.

Brdiczka, as reported by Slot,[4] described a case of myosarcoma of the duodenum in a woman aged 60,

From the Surgical and Pathological Services of Butterworth Hospital.

diagnosed by x-ray examination. The patient was operated on and a tumor the size of a baby's head was found in the right epigastrium attached to the bulb of the duodenum. The patient died suddenly at the end of one week of pulmonary embolism. There were no demonstrable metastases. This case was the second recorded in the literature and has not been mentioned in any other case report.

Andersen and Dooh [5] added a third case in 1933. A machinist aged 37 had been treated for duodenal ulcer for five years. He presented a recent acute loss of weight and edema of the lower extremities. He had had tarry stools for seven weeks and muscular weakness for three weeks. X-ray examination of the gastrointestinal tract was negative. A clinical diagnosis of carcinoma of the colon was made. Such conditions as retroperitoneal tumor, mesenteric tumor and kidney tumor were considered. The patient died without operation, very suddenly, of pulmonary embolism. At postmortem examination a large mass was found arising from the second and third portions of the duodenum which, judged by the description, was equal to the size of a fetal head. It was located in the right epigastrium and right hypochondrium. Ulceration and fistulization were found. There was no dilatation and no stenosis. There was thrombosis of the iliac and pulmonary veins. Histologically the mass was found to be a primary leiomyosarcoma.

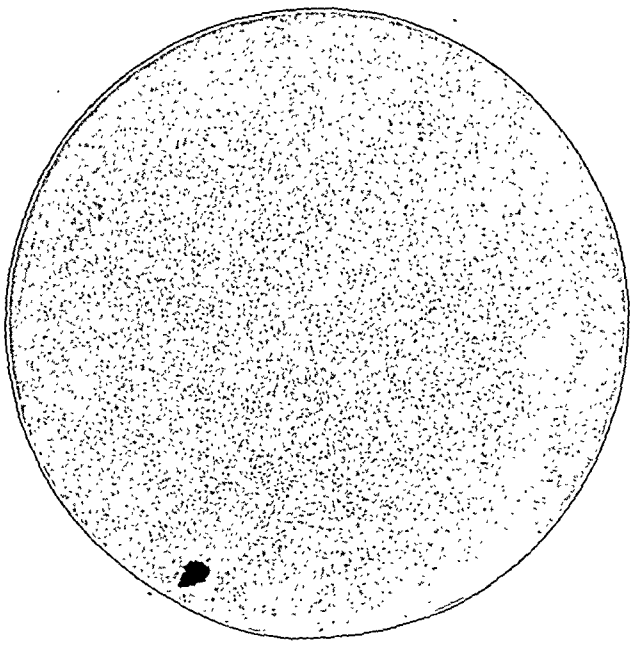

Fig. 1.—Section of leiomyosarcoma of the duodenum under low power.

Silverstone's [6] interesting case was the next to appear in the literature, in 1934. A woman aged 51 complained of epigastric pains, unrelated to food, at intervals for two years. However, the character of the pain had become more severe during the past two months. She had suffered from vomiting for three months. She also had a toxic adenoma of the thyroid. A diagnosis of duodenal tumor was not made before operation. At operation a tumor arising from the third portion of the duodenum and approximately the size and shape of a uterus was removed with a cuff of the duodenum, and the duodenum was sutured transversely. To relieve tension a posterior gastroenterostomy was performed. Death occurred on the fourth postoperative day from thyrotoxicosis. Autopsy revealed no leakage.

Seymour and Gould [7] reported the fifth and last case in 1936. A man aged 54 complained chiefly of pain in the abdomen, loss of weight, progressive jaundice and itching, all of three months' duration. He presented a mass in the epigastrium the size of a grapefruit. The roentgenologist reported "intraduodenal tumors or one lobulated tumor due to polyp or malignancy." There was no operation. Death occurred in less than four months from the time of first symptoms. Autopsy revealed a small tumor arising from the posterior wall of the first portion of the duodenum with ulceration, fistulization and abscess formation. No metastases were found.

REPORT OF AUTHORS' CASE

P. V., a white man aged 63, a laborer, referred to the surgical service of one of us (J. C. F.) at Butterworth Hospital by Dr. C. J. Geenen, April 6, 1937, complained chiefly of a mass in the abdomen which was first noticed three months before. It had been tender at times but there had been no gastric distress or difficulty in elimination by the bowel. He had lost 30 pounds (13.6 Kg.) since the appearance of the mass and had noticed considerable muscular weakness. The patient's past health had been excellent. The family history was negative for cancer and tuberculosis.

At examination a mass the size of a grapefruit was found just below the umbilicus behind the right rectus muscle. The mass was freely movable from side to side and could be displaced upward when the patient was in the recumbent position. The heart tones were of good quality, with a rate of 70, and regular. The blood pressure was 130 systolic and 80 diastolic. The urine was normal. The white blood cell count was 7,450; the red blood cell count was 4,600,000 and the hemoglobin content 100 per cent. X-ray examination of the gastrointestinal tract was negative for an intrinsic lesion, but the roentgenologist suggested a growth from without pressing on the transverse colon.

A clinical diagnosis of a tumor of the greater omentum or pedunculated retroperitoneal tumor was made. The possibility of a tumor of the transverse colon was considered.

The patient was prepared for operation by two days of rest in bed, irrigations of the colon and forced fluids. His blood was typed and it was found to be group IV by the Moss method. Suitable donors were obtained.

Operation was performed by one of us (J. C. F.) April 8. A right paramesial incision was made half above and half below the level of the umbilicus. When the peritoneum was opened a lobulated tumor the size of a fetal head presented. It was covered with peritoneum and had sufficient pedicle so that it could be delivered readily into the incision. The transverse colon and the greater omentum were above the tumor. The coils of the jejunum and ileum were below. The peritoneum covering the tumor was found to be the right half of the transverse mesocolon. The superior mesenteric artery and the greater vessels of the mesocolon were identified, both of which were gently retracted to the left after the peritoneum had been slit and stripped down on either side of the tumor. The dissection was carried down on the left side of the tumor parallel to the superior mesenteric artery, due precaution being used not to injury the artery. The tumor was shelled out readily until the pedicle was reached, at which point many small vessels were encountered. These were controlled by multiple forceps. The duodenum from which the tumor arose came into view. An abscess was encountered in the pedicle the size of an English walnut. Without much difficulty the tumor was freed down to the origin of the pedicle in the anterior wall of the duodenum just beyond the middle of the third portion. A cuff

of the wall of the bowel was excised, a clean removal of the entire mass being made. The vessels were ligated and a few small oozers were touched up with a Bovie cautery. The rent in the duodenum was closed transversely with one row of Connell's suture with chromic 0 and a second row of Lembert's suture with silk. It was felt that an insufficient lumen remained at the site of repair; hence a posterior duodenojejunostomy was quickly done from the terminal part of the second portion of the duodenum to a free loop of the jejunum without tension. The rent in the mesocolon was closed and anchored to the anastomosis with several interrupted sutures to prevent herniation. Pulsations of the midcolic artery and the superior mesenteric artery were present. A cigaret drain was inserted down to the transverse mesocolon to take care of slight soiling, which occurred from the abscess encountered in the tumor pedicle. The abdomen was closed in layers in the usual manner.

A pathologic report was made by one of us (W. P. L. McB.). On gross examination the specimen measured 10 by 6 by 6 cm. and had the appearance of multiple nodes that have become matted together. When the mass was sectioned it was found that some of the nodules had degenerated while others were intact. The cut section had a smooth homogeneous pink appearance resembling a sarcoma. There was no attempt at encapsulation. Microscopic examination revealed that the individual cells were arranged in bundles and were supported by a thin stroma. Some of the cells were slightly elongated while others were well rounded. They varied in size. Mitotic figures were not common and there was a moderate amount of round cell infiltration. The blood vessels were thin walled and in some areas they were quite numerous.

The patient was returned to his bed in good condition. A blood transfusion was administered the following day. He was kept well supported by fluids subcutaneously and intravenously. He made a smooth recovery until the eighth postoperative day, when an elevation of temperature to 101 F. developed. His pulse rose from 90 to 110 a minute. The twelfth day duodenal fluid escaped through the wound. Rigid treatment was instituted for the duodenal fistula without avail. The amount of duodenal contents escaping increased rapidly. The wound continued to slough in spite of all our efforts. Blood transfusions were given frequently and from 6,000 to 8,000 cc. daily of dextrose and saline solution was given intravenously and subcutaneously. The patient gradually failed and died on the twentieth postoperative day.

Postmortem examination was performed by one of us (W. P. L. McB.). The body showed moderate loss of weight. The thorax was well developed and there were no palpable lymph nodes. There had been a recent surgical incision in the upper part of the abdomen which had been covered with thick paste, and there was a rubber drain protruding from the incision. Permission was limited to abdominal exploration, which was accomplished by enlarging the surgical incision. The edges of this incision had been digested by the intestinal juices and the upper part of the abdomen was found to be filled with fecal matter. Examination showed that the suture line had been broken at the site of anastomosis, which allowed fecal matter and intestinal juices to escape. At the junction of the cecum and the ascending colon there was a complete separation of the bowel, and on closer examination the remains of a thrombosed vessel were seen beneath the serosa running parallel to the line of separation. The ends of the bowel at the point of separation were ragged and necrotic. It would appear that the thrombosed vessel produced a circular area of ischemia, which in turn was digested by the intestinal juices, permitting the intestine to separate. The liver showed a moderate amount of purplish mottling, the edges were rounded and no nodules were noted. The gallbladder was slightly distended but there was no stone in the common duct. The spleen was slightly enlarged and the cut surface was soft, pulpy and dark red. The pancreas was normal. The kidneys were not adherent to the surrounding fat, the capsule stripped easily leaving a smooth surface, and on cut section the pyramids were sharply outlined with the cortex of normal thickness. The adrenals, ureters bladder and prostate were normal. No demonstrable metastases to the lymph nodes were present.

On microscopic examination sections taken from the duodenum showed destruction of the mucosa and infiltration of the muscular coats with leukocytes. The serosa was covered with a purulent exudate. The liver showed cloudy swelling and chronic passive congestion. The spleen showed congested sinuses and a moderate number of inflammatory cells. Examination of the pancreas, adrenals, kidneys and bladder was negative.

COMMENT

Etiology.—The age incidence of leiomyosarcoma of the duodenum in the reported cases has varied between 34 and 67 years. Of the six patients with this condition on record, four have been men and two women.

Pathology.—In the strict sense of the word, the term leiomyosarcoma should be abandoned in favor of the term malignant myoma, the term sarcoma being reserved for malignant tumors with their origin in the connective tissue. But since the term has become an

Fig. 2.—Section of leiomyosarcoma of the duodenum under higher power than in figure 1.

accepted one in our present day literature there seems to be no reason to drop it. Malignancy, hemorrhage and degeneration are the outstanding characteristics of a sarcoma.

The histologic diagnosis of any sarcoma may be one of the easiest or one of the most difficult tasks that confront a pathologist, depending chiefly on the degree of differentiation. Those showing the least differentiation are usually the most malignant and to them the terms "small round cell sarcoma," "large round cell sarcoma," "mixed cell sarcoma" and the like have been applied. Here again an unsatisfactory nomenclature must be accepted. Conversely, the more differentiated the tumor becomes the less malignant it becomes and, as a corollary, the more it resembles some normal tissue. To these tumors the terms "fibrosarcoma," "myxosarcoma" and the like have been applied.

Hemorrhage in any new growth should arouse one's suspicions that it is liable to prove to be a sarcoma.

The vessels in this type of growth are thin walled, easily invaded and, according to Broders,[8] "the tumor cells grow right up to the vessel walls." Associated with hemorrhagic tendencies is the frequency of mucoid degeneration or, as in our case, liquefaction and suppuration of the tissue.

Leiomyosarcoma, on account of its source of origin in the muscular wall, tends to grow outward so that the lumen of the bowel is not encroached on. This is in contrast to lymphosarcoma, which tends to obliterate the lumen of the bowel.

Treatment.—Surgical removal, when feasible, offers the only hope of a cure. Since most of the tumors are pedunculated, complete removal with a cuff of the duodenum at the site of origin is often possible. If the lumen of the bowel is insufficient after closure of the rent, a short circuiting anastomosis may be made.

SUMMARY

The five cases of leiomyosarcoma that are reviewed and the sixth case that is reported here have many characteristics in common, which are as follows:

1. The usual period during which the patients were aware of symptoms was from seven weeks to three months. In three cases it was three months, in one case two months, in one case seven weeks and in one case it was not stated.

2. The most common site of origin was the third portion of the duodenum.

3. X-ray examination has failed in every instance to show constriction of the duodenum and has been of no aid in making the diagnosis except in one case, that of Brdiczka.

4. The size and shape of the tumor has been that of a fetal head in four cases, of a grapefruit in one case and of a uterus in one.

5. In no case has the tumor had a capsule. Necrosis, abscess formation and fistulization to the lumen of the bowel are common.

6. The growth does not cause stenosis or dilatation of the lumen of the bowel, and it grows by pushing the transverse mesocolon ahead; hence surgical removal without damage to the superior mesenteric artery and its branches is rendered difficult. Trauma to the vessel intima sustained by retraction may lead to thrombosis, which in turn may cause a breaking down in the anastomosis and other necrotic areas in the bowel, as in our case.

7. Four patients have undergone operation; one lived four months and three died within three weeks. Two patients were not subjected to operation; one lived four months and one died in one week. In every case death has been caused by pulmonary embolism or pulmonary thrombosis with one exception, namely the case of Silverstone, in which the cause of death was thyrotoxicosis.

Applicants Refused for Insurance.—Life insurance companies of the United States declined 335,000 applications for ordinary life insurance in 1937. How many of these who were refused suspected that they were not acceptable for life insurance is, of course, not known. Experience indicates that far the greatest number believed themselves to be in good health. —Sensenich, R. L.: The Quantity and Quality of Life, *Milwaukee M. Times*, April 1939.

STRAMONIUM POISONING

A REPORT OF TWO CASES

JOHN D. HUGHES, M.D.
AND
JAMES A. CLARK JR., M.D.
MEMPHIS, TENN.

Stramonium poisoning presents a definite clinical entity which has not been emphasized sufficiently in American medical literature. While it is not common, it does occur with enough frequency to warrant a thorough discussion of its manifestations, diagnosis, prognosis and treatment.

This form of poisoning follows ingestion of any part of the Jimson weed, a plant prevalent in this country and in all temperate and tropical zones. Jimson weed is only one of the various names by which it is known. Other names are Jamestown weed, thorn apple, stink weed, devil's apple and apple of Peru. Datura stramonium is the botanical term; the plant is a species of Solanaceae, or nightshade family. It is a large coarse herb which attains a height of from 3 to 6 feet, depending on the richness of the soil, with its branches almost as broad. The leaves are large and angular, from 4 to 6 inches long. The white flowers, which emit a strong sweet scent, are succeeded by egg-shaped seed capsules the size of a walnut and covered with numerous sharp spines. When ripe this seed vessel opens at the top, throwing back four valvelike forms and leaving a long central structure on which are many rough dark brown reniform seeds measuring 2 by 3 mm. All parts of the plant are poisonous, but especially the seeds, which contain the three alkaloids atropine, scopolamine (hyoscine) and hyoscyamine.

Datura stramonium, approximately one-third size.

Probably the first cases of stramonium poisoning reported in this country occurred in 1676 and are recorded by Beverley:[1]

> This being an early Plant, was gather'd very young for a boil'd salad, by some of the Soldiers sent thither, to pacifie the troubles of Bacon; and some of them ate plentifully of it, the effect of which was a very pleasant Comedy; for they turned natural Fools upon it for several Days. One would blow a Feather in the Air; another would dart straws at it with much Fury; and another stark naked was sitting up in a Corner, like a Monkey grinning and making Mows at them; a Fourth would fondly kiss and paw his Companions, and snear

in their Faces, with a Countenance more antik than any in a Dutch Droll. In this frantik Condition they were confined, lest they in their Folly should destroy themselves; though it was observed that all their Actions were full of Innocence and Good Nature. Indeed, they were not very cleanly; for they would have wallow'd in their own Excrements, if they had not been prevented. A Thousand such simple Tricks they play'd and after Eleven Days, return'd themselves again, not remembering anything that had pass'd.

An outbreak of stramonium poisoning equally striking and deserving particular emphasis because of the possibility of recurrence was described vividly by Garvin and Ruh [2] in 1923. Thirty boys, ranging in age from 6 to 8 years, picked and ate varying amounts of the seeds of the Jimson weed, which grew plentifully in the vicinity of their orphanage. Within a few hours, after the children had been put to bed, pandemonium broke loose. Some of the children began to bark like dogs, others tried to pick objects out of the air, while still others crawled under their beds crying and moaning. The visiting physician administered emetics and most of the patients were normal the next day, but several had a high fever for two or three days. It was noted that all the children had dilated pupils and a deep red flush over the entire body.

Watt and Breyer-Brandwyk [3] described an outbreak among forty-eight mine boys in Southwest Africa who had eaten beans containing the seeds of the stramonium plant. Ismael [4] recorded cases of poisoning from gruel which contained seeds that had been harvested with wheat.

The international aspect of this form of poisoning is reflected in the host of reports which are being added to the literature. Ismael [4] in Egypt, Mukopadhya [5] in India, Estapé and Bloise [6] in Uruguay, Neyron [7] in France, Howle [8] and Parkinson [9] in Australia, Van Ravenswaay [10] in the Netherlands and Grinnon,[11] Wilcox [12] and McNally [13] in the United States are only a few of the observers who have described this syndrome. By far the most complete summary on the subject is that of Jennings,[14] who reviewed the literature to 1935 and added two cases.

REPORT OF CASES

CASE 1.—J. Q., a white boy aged 13, was admitted to the John Gaston Hospital at 7:20 p. m. Sept. 25, 1938, in active delirium. The boy's father stated that the patient had seemed perfectly normal until about four hours before admission, when he rapidly lost consciousness, threshed wildly about and cried out incoherently. No history of premonitory symptoms could be elicited. One month before admission the patient had had chills, fever and sweats, in the order named, apparently malaria, "cured" by Groves chill tonic. There had been no relapses. The night prior to admission the patient, known to be asthmatic, had suffered a slight attack of asthma, which subsided spontaneously in two hours after he had vomited once. The father denied knowledge of all other symptoms, except that he had given his son two compound cathartic pills on the morning of admission, which resulted in one loose bowel movement associated with moderate bilateral lower abdominal griping.

At examination the patient was wildly delirious. He was well developed and well nourished and had an axillary temperature of 99 F., a rapid regular pulse rate of 150 a minute and a respiratory rate of 28 a minute. He was extremely restless, tossing all over the bed, picking at objects in the air and intermittently crying out shrilly. Choreiform movements of all four extremities were present, but there was no twitching of the face. The skin was flushed and dry. There was marked circumoral pallor but no exanthems. We were immediately struck by the extreme and equal dilatation of the pupils, remarking that he looked as though he had had a large dose of atropine. There was no reaction to light. The tongue was very dry and covered on the dorsum by a grayish fur. The mucous membranes of the mouth and throat were also flushed and dry. There were no exanthems. The rest of the examination of the head gave negative results. The neck was slightly stiff. Tachycardia was present, but otherwise the heart was normal. The lungs, abdomen and genitalia were all completely normal. Except for the active delirium, slight rigidity of the neck, choreiform movements and dilated pupils the neurologic examination gave negative results.

The laboratory procedures showed nothing abnormal except for a leukocyte count of 20,700 and an occasional estivo-autumnal malarial parasite. The spinal fluid was clear and colorless, flowed under normal pressure and contained 44 lymphocytes per cubic millimeter.

In spite of the leukocytosis and the bizarre physical signs, we immediately administered 15 grains (1 Gm.) of quinine dihydrochloride intramuscularly into the right buttock, fearing that we might be dealing with the pernicious comatose form of malaria. Three grains (0.2 Gm.) of soluble phenobarbital was given subcutaneously to control the mania, and a liter of 5 per cent dextrose in saline solution was administered every six hours by hypodermoclysis. Within a few hours he was sleeping quietly.

The next morning, twelve hours after admission, the patient recovered consciousness and stated that he did not remember anything that had transpired since 3 p. m. the previous afternoon. Except for marked thirst and blurred vision due to dilated pupils he had no complaints. His temperature, pulse rate and respiratory rate had returned to normal. The skin was no longer flushed, but the mouth was still dry. He drank tremendous quantities of water avidly.

Further questioning at this time revealed that two hours prior to the onset of his delirium he had gone out into a nearby field and had picked Jimson weed seeds, having been told that a tea brewed from these seeds was a sure cure for asthma. His mother poured four level tablespoonfuls of the seeds into a small kettle of boiling water and strained the tea through a cloth before giving him a cup of it. This he flavored with sugar and cream before drinking. He immediately began to feel drunk and had to lie down on his bed. He noticed extreme thirst and nervousness, which became progressively worse until he lost consciousness.

The patient was kept in the hospital for forty-eight hours and was then discharged free from symptoms, with the exception of moderate dilatation of the pupils.

A careful search in the records of the John Gaston Hospital revealed only one other case of stramonium poisoning:

CASE 2.—J. H., a Negro aged 18, was admitted to the John Gaston Hospital Aug. 4, 1937, because of irritability, dryness of the mouth and throat, wide dilatation of the pupils, which did not react to light, and exaggeration of the deep reflexes. The skin was hot and dry. The temperature was 102.4 F., the pulse rate 84 and the respiratory rate 20 a minute. Otherwise the physical examination gave negative results. He gave a

history of having drunk tea made of Jimson weed seeds. Three grains of soluble phenobarbital was administered subcutaneously. Within thirty minutes he was well sedated, and he slept quietly all night. The next morning, eleven hours after admission, he appeared normal except for dilated pupils and said that he felt all right. At that time his temperature was 98.4 F., his pulse rate 88 and his respiratory rate 18. He was discharged from the hospital free from symptoms.

The symptoms, treatment and prognosis of stramonium poisoning have been beautifully reviewed by Jennings. He emphasized that the form in which the drug is taken has a great deal to do with the way it manifests itself clinically. When the seeds or leaves are eaten it may take hours for the symptoms to develop, because of the delay of absorption; when a tea made from the seeds is drunk, as in our two cases, the onset may occur within minutes. There may be variability not only in the time but also in the mode of onset. Poisoning by the seeds usually causes a maniacal picture, while ingestion of the leaves produces a comatose form. The degree of poisoning depends on the total quantity of the active principles of the weed absorbed, the potency of these principles, the promptness and the effectiveness of the treatment and the sensitivity of the patient to the three alkaloids atropine, scopolamine and hyoscyamine.

The maniacal form, as its name implies, is characterized by almost ceaseless and apparently purposeless activity. As in our first case, the symptoms may take the shape of choreiform movements of the extremities, with sudden almost clonic movements of the body. Both clonic and tonic convulsions have been reported by various authors. Associated with these convulsions may be opisthotonos simulating that of meningitis and, if the seizure lasts for any length of time, cyanosis. Patients with less severe involvement may engage in absurd pursuits such as picking at imaginary objects in the air, pretending that they are blowing feathers, laughing senselessly, barking like dogs, crawling under the bed, crying out repeatedly or pacing the room. Occasionally destructive impulses may come to the front, causing the patient to attack his attendants belligerently or to do himself bodily harm. A maniacal patient may rapidly go into coma.

The comatose form varies from mild stupor to profound coma with the loss of conjunctival and corneal reflexes. Depending on the depth of the coma, the patient may be easily aroused or may progress into a state of collapse with failing pulse, subnormal temperature, depressed respirations and deep cyanosis. Death sometimes follows, especially if heroic treatment is not administered without delay.

Two premonitory symptoms should be stressed: progressively increasing thirst and disturbances of vision. The patient may drink enormous quantities of water, as in case 1. Visual disturbances are readily accounted for by the marked dilatation of the pupils. Various other early symptoms have been described, such as a feeling of intoxication, euphoria, irritability, restlessness and fear. An occasional patient may suddenly lose consciousness without having noticed any of these prodromes.

The chief observation on physical examination is excessive dilatation of the pupils. In practically no other condition is mydriasis so extreme. There is no reaction to light or to accommodation. Second in importance is the condition of the skin, which is usually flushed, hot and dry. So vivid may be the diffuse erythema that it may simulate the flush of scarlet fever. Occasionally a nonpunctate scarlatiniform rash is present. The lips, tongue and buccal and pharyngeal mucosa are dry and diffusely hyperemic unless collapse with cyanosis is present. The neck may be slightly stiff, as in case 1. Tachycardia is almost invariably present, the pulse rate sometimes being as high as 140 a minute. According to Ismael, the rapidity of the pulse is the best index of the degree of intoxication. Fever may or may not be present; the temperature has been found to be as high as 105 F. Subnormal temperature accompanies collapse. The respiration is usually increased, but in the comatose form it is frequently depressed. Cheyne-Stokes and Kussmaul breathing have been reported. Vomiting, marked obstipation and urinary retention may complete the picture.

The duration of the symptoms depends on the amount of the active principles of the weed ingested, the potency of these principles, the sensitivity of the patient and the promptness and effectiveness of treatment. Most patients recover in one or two days except for the mydriasis, which may persist for a week or longer. When large quantities of the seeds are not evacuated from the gastrointestinal system, slow continuous absorption of the alkaloids occurs and the acute symptoms may persist for days, ending in collapse or slow improvement. McNally cited the case of a 7 year old boy who died in coma thirteen hours after eating 120 seeds. Other deaths have occurred.

Sequelae are not common. Transitory disorientation may persist for a few days, but usually the higher faculties are not damaged. However, cases of permanent insanity and complete amentia have been recorded.

Treatment to be effective must be prompt. As soon as the diagnosis is made or suspected the stomach should be lavaged with water or with 4 per cent tannic acid solution, which precipitates the alkaloids. While the stomach tube is in situ it is advisable to administer a large dose of magnesium sulfate, in order to sweep the poison out of the intestine. If any difficulty is met in passing the tube, emetics such as ipecac, mustard or apomorphine should be given without delay. A drop of croton oil has been recommended for its purgative effect.

Various sedatives may be employed to quiet the patient. In both of our cases we obtained good results with 3 grains of soluble phenobarbital administered subcutaneously. Paraldehyde by rectum, 25 per cent solution of magnesium sulfate intramuscularly, barbital and other barbiturates have been highly effective. Morphine is contraindicated because of its tendency to cause cerebral congestion and because of its known synergistic action with atropine and scopolamine, two of the three alkaloids of Datura stramonium. It is hardly necessary to add that a dark quiet room is conducive to sedation. Warm packs are thought to be of aid in relaxing the patient and in causing diaphoresis, which hastens excretion of the drugs.

Ismael, who had wide experience with stramonium poisoning in Egypt, recommended the use of pilocarpine as a physiologic antidote. Pharmacologically this drug would seem to be definitely indicated, since it has an antagonistic effect on the parasympathetic nervous system, but, as Jennings pointed out, the dose needed is impossible to determine, since it is so difficult to estimate the amount of poisonous alkaloids ingested. The safest way to give it is in small repeated doses, regulated according to the reaction of the patient. In elderly people it may cause pulmonary edema.

BLOOD SUGAR VERSUS URINE SUGAR

AS OBSERVED IN PATIENTS TREATED WITH PROTAMINE ZINC INSULIN AND WITH ORDINARY INSULIN

ANTHONY SINDONI JR., M.D.
Chief of Diseases of Metabolism of the Philadelphia General and St. Agnes Hospitals; Chief Metabolic Consultant at the American Oncologic Hospital
PHILADELPHIA

If one reviews the literature on diabetes, especially the mode of diagnosis, the prognosis and the guidance of its treatment, one will find that the great majority of physicians depend much on the chemical analysis of the urine for sugar (dextrose). Indeed, this procedure has many practical advantages: it is easy to obtain a specimen and the examination may be made by the patient, it can be done within a few minutes and repeated as often as desired by the patient or the physician, it is free from the dangers of infection, and the apparatus is simply carried about.

For many years laboratory workers throughout the world have attempted to construct a satisfactory qualitative and quantitative method of studying substances that simulate reducing carbohydrate (true sugar or dextrose) in the urine. Up until the last few decades a reliable study of the elimination of sugar in the urine has been practically impossible because of the lack of proper or suitable technic.

PRODUCTION OF GLYCOSURIA

Since the adoption of the Benedict and the Fehling tests or some modification of them, physicians and laboratory workers have tried to determine more accurately the individual renal threshold for dextrose so as to enable the physician to calculate the diabetic patient's diet, estimate his insulin dose and govern his activities, thus intimately relating the renal threshold with the problem of the relationship of glycosuria to glycemia.

The term "glycosuria" itself has aroused much speculation. Many physicians use the term to indicate the first appearance of sugar in the urine. Benedict and his co-workers [1] feel that progress in the study of carbohydrate metabolism would be more rapid if the term "glycosuria" could be abolished. Since there is a constant presence of minimal traces of sugar in the normal urine, the term is without special significance and is misleading. They suggest employing the term "glycuresis" to indicate increased sugar, not a new appearance of sugar in the urine.

Peters and Van Slyke,[2] in view of the sharp difference between ordinary excretion and glycosuria, interpret the term "glycosuria" as the extraordinary appearance of dextrose in urine, and they feel justified in retaining the term "glycosuria." They also state that "the reduction of Fehling's or Benedict's copper solution may be due to nonglucose substances such as lactose or pentoses, or to a mere concentration in a urine of small volume per hour, of the unidentified reducing substances present in every normal urine, but ordinarily in too great dilution to affect the copper reagents used." [2]

Sherrill and MacKay [3] state that the normal retention of dextrose in the blood by the kidney appears in all probability to be brought about by the almost complete reabsorption by the tubules of dextrose that is filtered from the plasma in the glomerular filtrate. They feel that this reabsorption is normally not absolutely complete, since Peters and Van Slyke [2] and others have shown that the ordinary urine of all normal persons contains small quantities of reducing substances which could be found by the use of methods sensitive to low concentrations but not by the ordinary qualitative sugar test with Fehling's or Benedict's copper solution. This amount in the urine they state is equivalent to about 0.3 to 1.5 Gm. of dextrose excreted in twenty-four hours in a concentration of from 0.02 to 0.10 per cent and for practical purposes may be considered negative.

In view of the general acceptance of the fact that renal threshold for dextrose is considered to be that concentration of sugar in the blood above which sugar appears in the urine, Sherrill and MacKay [3] conclude from their observation that this threshold for dextrose is that concentration of dextrose in the plasma at which the reabsorption of dextrose by the renal tubules from the glomerular filtrate is insufficient to prevent the excretion of an appreciable quantity of dextrose in the urine. A factor they feel in determining this concentration is the degree of renal activity—not alone the number of functioning renal units but the activity of these or the volume of glomerular filtrate being formed in each individual unit. Van Slyke [4] states that, if the renal tubules are not normally active in the reabsorption, dextrose may get through into the urine even when the blood sugar content registers normal. In that case a condition of renal "glycosuria" exists. Also this not infrequently occurs in patients with the degenerative type of nephrosis.

Page and Corcoran [5] are of the opinion that the presence of sugar in the urine will depend on the efficiency of the tubular mechanism and on the blood sugar level. "From contemporary evidence," they state, "it appears likely that the reabsorption of carbohydrate by renal tubules, like the secretion of phenol red, is dependent upon the presence of some hypothetical body in tubule cells which acts as a transfer mechanism." Ni and Rehberg [6] have shown the content of dextrose in the reabsorbed fluid to vary between 168 mg. and 498 mg. per hundred cubic centimeters; they also have observed greater variations and that sugar reabsorption goes on all the time but that the increase is less and less as the blood sugar gets higher. They are of the opinion that one of the factors determining the reabsorption of sugar may be the difference of concentration between blood and urine at the place of reabsorption. Himsworth [7] concludes from his observation that the concentration of the sugar reabsorbed is determined by the sugar content of the blood in the peritubular capillaries.

Hawkins and his co-workers [8] feel that the only reasonable method of expressing the dextrose in the urine is in the rate of dextrose excreted per unit of

The diets prescribed in this study were prepared under the direction of Mary Ann Carver, B.S., chief dietitian of the diabetic department of the Philadelphia General Hospital. The laboratory details of the experiment were carried out by Daniel Klein, Ph.D., chief chemist of the diabetic department, and his two associates Miss Mildred Inwood, B.S., and Miss Mildred Rose. Drs. Leon Smelo and Philip Gerber gave the author valuable assistance.

time. Benedict and his co-workers [1] feel that the volume of urine and qualitative tests are of little significance and that the real criterion is absolute quantity of sugar eliminated per hour. Sugar, they say, may undergo variations as wide as 100 per cent or more in absolute amount per hour and in percentage in the urine. They feel that the relationship of sugar in the urine to the ingestion of food must be kept constant during such an experiment and that an accurate measure of the influence of any substance on the excretion of sugar can be determined only by a quantitative determination. Myers [9] believes that the intervals of the examination of the urine should not be much longer than two hours, or a significant sugar increase may be lost in the normal fluctuation for a longer time. Thus, according to Benedict and his colleagues [1] an increase of 15 mg. of sugar eliminated in the first two hours would usually be definitely positive while the same absolute increase in the urine of five or six hours might not warrant a definite conclusion.

DETERMINATION OF RENAL THRESHOLD FOR DEXTROSE

Himsworth feels that in view of the known variations of the blood sugar many investigators have based their conclusions on the presence or absence of sugar in a twenty-four hour specimen, in spite of the obvious inaccuracy of such conclusions. Frank [10] was able to show from observations two different blood sugar levels —one level at which sugar first appears in the urine and the other level at which sugar disappears in the urine; the former was the higher blood sugar level. Since his observations, other investigators have confirmed his results and have established two renal thresholds, one of appearance and the other of disappearance. Sherrill and his co-workers [3] have concluded from their experiments on the determination of the renal threshold for dextrose that "the threshold as a 'normal figure' is a misnomer; also that a normal average for the renal threshold should never be given because it may be misleading." They believe that for practical purposes the renal threshold for dextrose is of clinical interest only when dextrose is detected in the urine, for this indicates either hyperglycemia or a so-called renal diabetes. In the absence of sugar in the urine qualitatively, they feel that the renal threshold has no place. Williams and Humphreys' [11] studies of the renal threshold for sugar in diabetes found no constant blood sugar level for the appearance of urinary sugar. They concluded that diabetes should be controlled on the basis of the blood sugar level rather than by urine tests.

Since it is generally understood that the apparent renal "threshold" for dextrose of normal persons is that concentration of sugar in the blood above which the sugar appears in the urine, the average figures have been variously given for venous blood between 160 and 180 mg. per hundred cubic centimeters. But these figures are subject to much controversy. John [12] notes in a series of 337 cases of ambulatory patients with glycosuria, subjected to a dextrose tolerance test, that in 63 per cent the glycosuria was of the nondiabetic type and in 37 per cent of the diabetic type. He also observed cases in which no glycosuria was detected throughout the dextrose tolerance test, although the blood sugar rose very high, in certain cases above 200 mg. per hundred cubic centimeters. He concludes that there is no such thing as a normal "threshold" but that for all persons there is an individual "threshold." Lawrence [13] gives the average figures for renal "threshold" for sugar at about 0.17 to 0.19 per cent blood sugar and admits that variations occur in diabetes. These changes consist in a raising of the threshold above 0.2 or even 0.3 per cent blood sugar, with the result that urine tests for sugar give little indication of the satisfactory control of the disease, making the patient appear sugar free when the blood sugar is high. Mackay [14] concludes from his observations that the renal threshold for sugar, if there is one, is a much more variable factor than is generally supposed. Glassberg [15] states that the kidney threshold for dextrose shows wide individual differences. It may be below 100 or above 250 mg. of true blood dextrose. It appears independent of age and sex.

Richardson [16] observes that, if a renal threshold above 180 mg. is found, urine examinations cannot be depended on to maintain a satisfactory adjustment. Ward [17] found in routine blood sugar examinations of 257 patients that 110 of these patients had a hyperglycemia and twenty-six patients of the latter group glycosuria. He emphasized the practical value of routine blood sugar studies in the detection of disturbances of carbohydrate metabolism. Goto and Kuno's [18] studies on normal adults found renal threshold for dextrose to be between 114 and 231 mg. per hundred cubic centimeters. Campbell and his co-workers [19] conclude from their observations that the renal threshold for true sugar varies from 99 to 228 mg. per hundred cubic centimeters. Joslin [20] gives the average between 0.16 and and 0.18 per cent of sugar for the whole blood. Levinson and MacFate [21] give for renal threshold from 140 to 200 mg. per hundred cubic centimeters. Holst [22] observed that 70 per cent of the 150 persons who were refused life insurance because of glycosuria were found to have no pathologic condition and that in the remaining 30 per cent of this group diabetes developed in between five and sixteen years. Williams and Humphreys [11] also found persons rejected for life insurance and treated as diabetic patients because of the occasional or even frequent finding in the urine of copper reducing substance with a normal power to utilize dextrose.

Rabinowitch [23] emphasizes the fact in his observations that for certain persons, following the institution of insulin treatment the absence of sugar in the urine ceases to be a reliable index of progress. Major and

Davis [24] have observed diabetes with blood sugar ranges from 333 to 425 mg. per hundred cubic centimeters without glycosuria. Williams and Humphreys [11] say that in severe cases of nephritis patients may excrete small quantities of sugar in the urine, frequently giving rise to the misapprehension that true diabetes exists. Mason [25] found from his observations in acute nephritis that in hourly periods after the ingestion of 100 Gm. of dextrose the blood sugar values were elevated from 0.10 to 0.217 per cent without urinary sugar. He concludes that the renal threshold is elevated in acute nephritis. Myers and Bailey [26] found blood sugar levels to range from 0.10 to 0.22 mg. per hundred cubic centimeters with no glycosuria in twenty-three observations on seven patients with interstitial nephritis. Faber's [27] interpretation of glycosuria is conducive to possible error in two directions: "(*a*) Harmless excretion of sugar may be regarded as an incipient diabetes, an error which may have economic, social and, not least important, psychic consequences of a grave nature for the patient, (*b*) it will be just as unfortunate if early diabetes is regarded as benign glycosuria, for the mistake in such cases is often not discovered until the disease has progressed and is perhaps already so far advanced that the most appropriate time to attack and arrest its development has passed."

EXPERIMENTAL OBSERVATIONS

In view of this great diversity of opinion among so many investigators and clinical workers throughout the world concerning the relationship of glycosuria to glycemia in the problem of renal threshold for dextrose, and realizing that treatment of numerous diabetic patients is frequently guided by the results of the chemical analysis of the urine for sugar, my associates and I decided to ascertain in a large number of diabetic patients under our care the relationship of glycosuria to glycemia as produced by their regular prescribed diets and insulin (protamine and ordinary).

Of the large total number of diabetic patients under observation, studies on only sixty-one patients were tabulated because we felt that these were sufficient to explain our conclusions. There were twenty-seven males and thirty-four females; age variations were from 5 to 87 years. The duration of diabetes varied; some were unaware of the existence of diabetes until a few days before they entered the hospital; in others the diabetes had existed from several months to twenty-five years. Many suffered from more than one apparent complication, and the diabetes of the group was of varying severity.

The groups studied were those (1) on protamine zinc insulin, (2) on ordinary insulin, (3) on protamine and ordinary insulin and (4) on diet alone. The insulin (both forms) prescribed was given within fifteen to twenty minutes after meals [28]—the protamine, when prescribed with the ordinary insulin, was given immediately after it. In a few cases protamine zinc insulin alone was given after either breakfast or supper for one meal, while the ordinary insulin was given after the other meal (breakfast or supper). No form of insulin was prescribed for lunch.

We realize that the paramount disturbance in diabetes is in the power of oxidizing the carbohydrate of the meal and that the chief rise in blood sugar and the greatest likelihood of glycosuria, whether in mild or in severe diabetes, occurs usually after the morning meal [29]. In mild diabetes the fasting blood sugar is not infrequently within the normal range, but following the meals it often rises to various abnormal levels [8]. For this reason we obtained our blood specimen for the estimation of dextrose after breakfast (one and two hours), while the urine specimen was taken within the three hour interval after breakfast, after the fasting urine had been discarded.

All the patients under observation emptied the bladder (fasting urine) in the morning before breakfast, after which they ate their regular prescribed breakfast followed by insulin (ordinary or protamine or both) if prescribed. An hour later a blood specimen (venous) was obtained and another an hour later (one to two hour specimens) for the estimation of dextrose. All the urine voided within three hours after breakfast was examined for dextrose content in grams.

In our blood sugar estimation we obtained venous blood in preference to the arterial (capillary or cutaneous). We realize that the ideal condition would be to use arterial plasma; but this is not practical, and it has become customary to use the whole blood. The reason for the venous method is that it is the one generally carried out in our department.

There is much diverse opinion as to the arteriovenous difference in blood sugar, in spite of the fact that the consensus is that in normal persons the postprandial blood sugar is usually slightly higher in the arterial than in the venous, but in the fasting state the sugar content of the two bloods is usually the same. In moderate diabetes the divergence between arterial and venous blood sugars is diminished, and in severe diabetes it may be absent or even reversed, the venous blood sugar actually exceeding the arterial.[2] Rabinowitch [30] points out that the absence of any arteriovenous difference in the presence of hyperglycemia following the ingestion of dextrose appears to be an indication for the use of insulin. Peters and Van Slyke [2] state that the presence of arteriovenous difference does not preclude but that its absence strongly indicates true diabetes. In view of the fact that our examinations of blood sugar were made following breakfast and were not fasting, and that the blood sugar concentration (postprandial) is usually higher in the arterial than in the venous, we may interpret our venous blood sugar concentration to be lower than the arterial for those on insulin therapy if we accept Lawrence's [31] explanation that insulin restores the normal difference between arterial and venous blood sugar in those diabetic patients in whom it did not exist.

The diets prescribed ranged from 100 to 250 Gm. of carbohydrate, from 60 to 100 Gm. of protein and from 80 to 150 Gm. of fat daily, well balanced, rich in vitamins and all the essential elements.

Thus in our group of patients each averaged approximately a total of three blood sugar examinations for each of the two hours following breakfast and three urine tests for dextrose within the three hour interval. The postprandial examinations (blood and urine sugar) were repeated at intervals of five or more days. In table 5 are tabulated results of separate examinations. Because of the difficulties frequently encountered, especially among the elderly diabetic patients, in obtaining a specimen of urine, we utilized the three hour interval after breakfast for obtaining the urine, withdrawing specimens of the blood at the end of each one and two hour (postprandial) interval.

In our method of administering insulin we tried to avoid the sudden alteration or reduction of the blood sugar levels so as to reduce the possibility that occurs occasionally of instances in which the threshold of appearance is higher than the threshold of disappearance, probably causing glycosuria to occur on one occasion and not in another, with a blood sugar of approximately the same level or value. By preference we slowly reduced the blood sugar level and thereby attained more accurate results.

In the twenty-four hour urine study we took another group of fourteen patients on insulin (protamine and ordinary and the two combined). The total urine voided in twenty-four hours was collected and examined for the number of grams of dextrose. The blood sugar estimations were made one and two hours after breakfast. Not infrequently the fasting blood sugar was taken in conjunction with postprandial blood sugars as shown in table 6.

RESULTS

We observed, as shown in table 1 (zero group), patients with a total average blood sugar level above normal, occasionally over 200 mg. per hundred cubic centimeters at the end of the first or the second hour who had no "spill" or excretion of dextrose in the urine. In the individual blood sugar examinations of these patients following their breakfast (postprandial) practically the same observations were found. Higher blood sugar levels without glycosuria were observed with both forms of insulin therapy (ordinary and protamine zinc insulin) than with either insulin alone or without insulin.

Table 2 classifies a group of patients whose average spill was less than 1 Gm. of dextrose in the urine. This amount of excretion in the urine is often considered of "no significance" by many physicians. But in this group one finds that many of the patients averaging high levels of blood sugar at the end of the first and second hour spilled less dextrose in the urine than did those averaging low levels of blood sugar.

TABLE 4.—*Average Blood Sugar Levels with Average Excretion of Dextrose Exceeding 5 Gm.*

Case	Sex	Age	Complications	Insulin per Day: Protamine	Insulin per Day: Ordinary	Insulin per Day: Total	Blood Sugar: 1 Hr.	Blood Sugar: 2 Hr.	Urine Sugar in Grams

In the separate or individual blood sugar examinations of these same patients, as in case 15 on ordinary insulin, we found that the blood sugar level at the end

30. Rabinowitch, I. M.: Simultaneous Determination of Arterial and Venous Blood Sugars in Diabetic Individuals, Brit. J. Exper. Path. 8: 76-84 (Feb.) 1927.

31. Lawrence, R. D.: Effect of Insulin on the Sugar Content of Arterial and Venous Blood in Diabetes, Brit. M. J. 1: 516 (March 22) 1924.

of the first hour after breakfast rose to 296 mg. per hundred cubic centimeters; at the end of the second hour it descended to 212 mg. with no spill of the dextrose in the urine within the three hour period. At another interval, a few days later, it ascended to 320 mg. per hundred cubic centimeters at the end of the first hour and descended to 234 mg. at the end of the second hour with 17 Gm. of dextrose in the urine. In case 18 on protamine and ordinary insulin at the end of the first hour the patient's blood sugar level was 292 mg. per hundred cubic centimeters; the second hour it descended to 240 mg. with a spill of 0.3 Gm. of dextrose in the urine. At another interval, three days later, at the end of the first hour it was 232 mg. and the second hour 210 mg. with no spill of dextrose in the urine. In case 25, on protamine and ordinary insulin at the end of the first hour the blood sugar was 157 mg. per hundred cubic centimeters; the second hour it descended to 123 mg. and 0.8 Gm. of dextrose was spilled in the urine; at another interval, the next day the first hour the blood sugar rose to 208 mg. per hundred cubic centimeters; the second hour it descended to 180 mg. with no spill of dextrose in the urine. In case 56, on protamine zinc insulin in the first hour the blood sugar level was 162 mg. per hundred cubic centimeters, the second hour 172 mg., and 0.7 Gm. of dextrose was spilled in the urine; at another interval, two days later, it was 284 mg. the first hour and 370 mg. the second hour and 0.6 Gm. was spilled in the urine. In case 71, without insulin the blood sugar at the first hour was 134 mg., 155 mg. the second hour, and 2.8 Gm. was spilled; at another interval, several days later, the blood sugar the first hour was 224 mg., the second hour 206 mg., with no spill.

				..	..	..	204	162	0.8

Thus the amount of excretion or spill of dextrose in the urine after breakfast in relation to the blood sugar levels in the individual patients observed in these cases appears to correspond with that of the patients whose averages are given in table 2, in that many of the patients with high blood sugar levels spilled less dextrose than those with low blood sugar levels.

These patients spilled an average of between 1 and 5 Gm. of dextrose in the urine. There were a few patients with low average levels of blood sugar whose average spill within the three hour period was greater than those with a high level of blood sugar; e. g., compare case 51 with case 49; case 36 compared with the rest with the exception of cases 13, 47 and 62. We have also observed that patients excreting or spilling occasional dextrose in the urine, approximately the same amount within three hours after their breakfast, had variable blood sugar levels at the end of the first and second hour (cases 13, 12, 16, 45, 42, 37, 32, 63, 62 and 50).

In table 4 are grouped those patients who excreted a total average of dextrose in the urine above 5 Gm. In this group are some patients whose average spill of dextrose in the urine was greater with a low level of blood sugar than others with a high level, as in case 29 compared with the rest of the group excepting case 76.

In this group are also patients whose average blood sugar levels were lower but who were excreting more dextrose than many of those with higher blood sugar in other tables (those in the group in table 3 whose average spill was between 1 and 5 Gm.). A few also in table 2 who spilled less than 1 Gm. approached the blood sugar levels of those in table 4.

In comparing the average blood sugar levels given in table 4 with the individual blood sugar levels of those

of other groups, such as those in table 5, one finds that many of the patients shown in table 5 at infrequent intervals had higher blood sugar levels with no spill, as in cases 1, 12, 15, 18, 19 and 38.

Table 6 includes a few of the patients whose blood sugar level after meals was far above normal but whose twenty-four hour urine was normal. This was observed in patients given combined protamine zinc insulin and ordinary insulin as well as in patients given ordinary insulin or protamine zinc insulin alone. Blood sugar as high as 390 mg. per hundred cubic centimeters one hour after breakfast was observed with normal twenty-four hour urine on ordinary insulin alone. With the exception of a few, the majority of the patients on the protamine and ordinary insulin therapy maintained moderately higher average levels of blood sugar after meals with normal twenty-four hour urine than those with either form of insulin alone. Our examination revealed that at one interval a patient excreted a variable amount of dextrose although having a lower postprandial blood sugar level than at another interval when the postprandial blood sugar level was high and analysis of the urine negative for sugar. These results occurred not only in different patients but also in the same patient at different times.

(To be continued)

Clinical Notes, Suggestions and New Instruments

NONTROPICAL SPRUE

A. L. BURGDORF, M.D., HARTFORD, CONN., AND THOMAS A. BARRY, M.D., BRIDGEPORT, CONN.

This case of nontropical sprue is reported because of the typical exacerbations with the patient on a faulty diet, the repeated remissions with the patient on a hospital sprue regimen, the association with a previously performed gastro-enterostomy, the marked loss of stature and the not unusual negative postmortem observations. The patient was hospitalized four times for sprue in a period of five years and three months and spent seventeen and one-half months in three different hospitals. The records from all these institutions are here brought together.

REPORT OF CASE

History and Examination.—A man aged 42, a chef, first seen by one of us on his first admission to the King County Hospital at Seattle May 21, 1931, had not been in the tropics. His complaints were diarrhea, weakness, loss of weight, pain in the back and swelling of the lower extremities. For many years he had had stomach trouble marked by postprandial epigastric pain usually relieved by food or soda, and certain types of food were very irritating to him. He recalled having been extremely and dangerously ill in 1918 with a gastric complaint associated with marked vomiting. From 1918 to 1925 he had constant recurrences of gastric pain and vomiting. In 1925 a gastro-enterostomy for "an ulcer of the distal end of the stomach and one in the colon" gave complete relief of previous complaints, but he commenced to have light yellow stools, occasionally but not always of a foul odor. From 1928 to the time of admission his stools had been watery and there were from five to eight a day with no blood or mucus. In the period of six or eight months prior to admission he lost about 40 pounds (18 Kg.). In the past year he had had edema occasionally. He was emaciated, weighing 115 pounds (52 Kg.), and was 5 feet 7 inches (170 cm.) tall, with a markedly protruding abdomen, slight pitting edema of the lower extremities, a shuffling gait and tenderness over an area on both sides of the vertebral column from the ninth to the twelfth vertebra.

Course.—During the first two months of hospitalization a mycelium resembling Monilia psilosis was isolated on one occasion from the stool. Marked anemia of the pernicious type developed, the red cell count falling from 3,750,000 to 2,630,000 and the hemoglobin content from 87 per cent to 50 per cent. The serum calcium content ranged between 5 mg. and 9.6 mg. per hundred cubic centimeters. X-ray studies revealed marked decalcification of the bones, a functional gastro-enterostomy passage and what appeared to be an old compression fracture of the twelfth dorsal vertebra. His edema vanished with bed rest, returned and again disappeared after the administration of ammonium chloride and salyrgan. With cod liver oil and a low fat, low carbohydrate and high protein diet he improved, although diarrhea was intermittently present. He was transferred to the convalescent unit of the hospital, where he received a general diet, radiant heat, general ultraviolet radiation and massage. He was discharged markedly improved. No laboratory data were gathered at the time of discharge.

A summary of the hematologic studies and serum calcium determinations made during his stay in this hospital, together with the determinations made during his subsequent hospitalizations, is presented in the accompanying table.

After his discharge Jan. 3, 1932, the patient was fairly well with a general diet and calcium taken by mouth. His appetite was good. He was physically able to drive an automobile and trailer from Seattle to Huntington, Long Island, N. Y. In November, eleven months after discharge, he contracted influenza and spent two weeks in bed. After this attack he rapidly lost vitality and weight (40 pounds; 18 Kg.). By March 1933, fourteen months after discharge from the hospital, his chronic diarrhea was again well established, the pain in his back had returned, edema of the ankles had reappeared and he was unable to regain weight. He was admitted to the Roosevelt Hospital, New York, December 27, complaining of diarrhea, yellow frothy stools and weakness. He had had a sore tongue and tetanic cramps in his hands for three weeks. His appearance and the results of examination were the same as on his previous hospitalization except that he was now definitely kyphotic and his knee jerks were hypo-active. The musculature was markedly wasted. The blood calcium content was 6 mg. and the serum phosphorus 3.5 mg. per hundred cubic centimeters December 28. A blood count showed 2,700,000 red cells per cubic millimeter, with a hemoglobin content of 65 per cent. With a Turner sprue diet, a reduced iron intake, liver extract given intramuscularly, calcium lactate, viosterol and ultraviolet radiation, in three weeks the serum calcium content had risen to 10 mg., the hemoglobin to 80 per cent and the red cell count to 2,780,000. X-ray studies of his bones again showed marked general osteoporosis. X-ray study of his gastrointestinal tract demonstrated a deformity of the duodenal cap and a functioning gastro-enterostomy passage. May 5, 1934, after a hospital stay of about five months, he was discharged for convalescence to the Burke Foundation, where he remained two weeks.

For the next months he restricted his activities somewhat but was strong enough to walk about daily. His appetite was good; his diet, however, was not always correct, since he frequently increased his carbohydrate at the expense of his proteins, and occasionally the total caloric requirement was not obtainable.

December 13 he reentered the Roosevelt Hospital with a history of having had fainting spells and attacks of unconsciousness, emotional upsets, a decrease in weight from 100 to 88 pounds (45 to 40 Kg.), gas after meals, dyspnea and, during the two weeks before admission, nausea, vomiting and diarrhea.

At this third hospital admission within a three and one-half year period the same physical signs were noted except that his emaciation had increased and his deformity had become accentuated. His blood pressure was 70/46 and his reflexes were hyperactive instead of hypo-active, as on the previous admission. Trousseau and Chvostek signs were absent. The serum calcium content had fallen to 6.3 mg. per hundred cubic centimeters, and a blood count showed 42 per cent hemoglobin and 2,080,000 red cells. During his five week stay he gradually improved and gained weight on a high protein, high vitamin and high calcium diet. His diarrhea was controlled and his general condition improved. His last blood study showed a calcium content of 8.3 mg. and a phosphorus content of 3.95 mg. per hundred cubic centimeters. The hemoglobin had risen to 60 per cent and the number of red cells to 3,100,000. He

left at his own request Jan. 18, 1935, with a diagnosis of recurrent sprue following gastro-enterostomy.

For seventeen and one-half months after discharge he lived outside of a hospital. During this time he attempted to take a high protein diet with calcium and viosterol. He had an occasional moderate attack of diarrhea but rarely vomited and was physically capable of driving a car and of carrying on modified activity. By April 1935 his general condition had improved, his appetite was good, he had returned to a general diet and he was able to resume his occupation on a small scale by making and selling sandwiches in a tavern. In November he again started to fail, lost weight and had a recrudescence of his chronic diarrhea. About Aug. 20, 1936, he had an acute attack of nausea and vomiting accompanied by loss of weight which lasted for one week, at the end of which time he was seized with intense epigastric pain associated with considerable abdominal rigidity. August 27 he was admitted to the Bridgeport Hospital, his fourth and last hospital admission in five years.

His complaint was severe abdominal pain of eight hours' duration. He was poorly developed, extremely undernourished, in no apparent distress, apathetic, cooperative and slightly

tender over the epigastrium. There was slight spasm of the upper abdominal muscles. Laboratory examinations showed hemoglobin values of 80 per cent and 78 per cent, red cell counts of 3,350,000 and 3,050,000 and white cell counts of 45,700 and 38,750. Among the leukocytes toxic granules were observed, and of the leukocytes 38 per cent were banded types, 23 per cent metamyelocytes, 3 per cent myelocytes and 1 per cent large lymphocytes. The serum calcium content was 6.4 *mg. per hundred cubic centimeters.*

He failed to respond to any form of treatment and four days after admission died.

Autopsy.—Postmortem examination revealed physical deformities as a result of bone absorption; these were most marked in the vertebral column, so that the body height had decreased 7 inches (18 cm.) after the first hospitalization in 1931.

A posterior gastro-enterostomy passage was identified, but no evidence either gross or microscopic of pathologic change involving the stomach, pylorus or duodenum could be established. There was moderate hypoplasia of the bone marrow with numerous megakaryocytes. Cultures of material from the colon and small intestine were negative for pathogenic organisms.

COMMENT

There appear numerous references in the literature to the sprue syndrome associated with involvement of the duodenum. The possibility exists in this instance, in view of the lack of evidence at autopsy of gross duodenal disease, that the recurrent preoperative and postoperative epigastric distress was a part of the early symptoms of nontropical sprue, of which the more characteristic signs developed later.

THE RELIEF OF ARTHRITIC SYMPTOMS FOLLOWING URTICARIA

WILLIAM B. RAWLS, M.D., NEW YORK

In 1933 Hench [1] reported analgesia accompanying hepatitis and jaundice in cases of arthritis, fibrositis and sciatic pain. The exact mechanism responsible for the improvement in these cases has not been determined.

After this observation he produced artificial jaundice by the *intravenous administration of bilirubin. The results obtained,* however, were not entirely satisfactory and were not comparable to those observed after natural jaundice.[2] Thompson and Wyatt [3] reported that the results of injections were not as satisfactory when bilirubin was used alone as when it was combined with the sodium salt of dehydrocholic acid (decholin sodium).

It is doubtful, however, that the results of either natural or artificial jaundice are due entirely to the increased serum bilirubin, because relief of symptoms has been observed when there was no evidence of jaundice. In a previous paper I [4] reported that the relief of arthritic pain followed an attack of urticaria induced by cinchophen when there was no evidence of jaundice. In Hench's [1] case 16 complete cessation of pain followed urticaria after administration of cinchophen six weeks before the onset of visible jaundice. Two patients in his series who were given cinchophen experienced relief of the arthritic symptoms before the onset of visible jaundice, but there was *no urticaria.*

In a study of the relation between cutaneous sensitivity, hepatic function, leukopenic index and toxic effects from cinchophen,[5] urticaria followed the administration of cinchophen in nine cases and there was relief from arthritic symptoms in five of these. There was a slight elevation of the icterus index and serum bilirubin value in some instances, but they remained below the icteric stage. (I considered the normal icterus index to be between 4 and 8 and the normal serum bilirubin value 1 mg. per liter or below. I have found in my study that jaundice is not usually visible until the icterus index is 20 or above and in most instances around 25.) This indicated, as Hench [1] and I [4] have previously suggested, that the relief obtained in jaundice might be due to other factors besides increased bilirubin.

Consequently it was considered advisable to report in detail cases in which relief followed urticaria, with the hope that this might stimulate further study of the phenomenon.

REPORT OF CASES

CASE 1.—L. B., a woman aged 28, had rheumatoid arthritis involving the hands, elbows, shoulders, knees and feet. Cinchophen 7½ grains (0.5 Gm.) was given three times a day

4. Rawls, W. B., in discussion on Hench, P. S.: The Effect of Jaundice on Chronic Infectious Arthritis and on Primary Fibrositis, J. A. M. A. **109**: 1481 (Oct. 30) 1937.

5. Rawls, W. B.; Gruskin, B. J.; Ressa, A. A., and Gordon, A. S.: The Relation Between Skin Sensitivity, Liver Function, Leukopenic Index and Toxic Effects from Cinchophen, J. Lab. & Clin. Med., to be published.

for six days (total 135 grains, or 8.7 Gm.), after which severe urticaria developed, lasting seven days. Immediate partial relief (grade 2) [6] of the arthritic symptoms followed the onset of the urticaria, and at the end of seven days the pain, soreness, swelling and stiffness of the joints had almost entirely disappeared (grade 3). This was one of the first cases observed, and the icterus index before the administration of cinchophen was not determined but there was no visible jaundice at any time. On the tenth day following the onset of the urticaria, however, the icterus index was 8.7. The patient remained symptom free for five months and stated that it was the best period she had experienced in several years.

CASE 2.—M. S., a woman aged 68, had mixed arthritis involving the feet, ankles, knees, wrists and hands. Cinchophen 7½ grains (0.5 Gm.) was given three times a day for two weeks (total 315 grains, or 20.4 Gm.), after which severe urticaria developed lasting seven days and involving the entire body. There was complete relief within twenty-four hours after the onset of the urticaria, and the patient remained symptom free for five weeks. The symptoms then returned but were less severe (grade 2) for another three weeks. There was only slight relief from the cinchophen per se but the relief following the urticaria was striking. The liver function tests gave normal results. The icterus index was 6 before and 8 after the administration of cinchophen. There was no visible jaundice at any time.

CASE 3.—A. P., a woman aged 59, had mixed arthritis involving the hands, wrists, shoulders, knees and feet. Cinchophen 7½ grains (0.5 Gm.) was given three times a day for five days (total 112½ grains, or 7.3 Gm.), after which urticaria developed; this was associated with angioneurotic edema of the lips, tongue and mouth and lasted four days. With the disappearance of the urticaria there was marked relief (grade 3) of the joint symptoms, although there had been some increase in the joint symptoms during the attack of urticaria. The relief persisted for six weeks. Liver function tests gave normal results. The icterus index was 5.9 before and 8 after administration of cinchophen. There was no visible jaundice.

CASE 4.—C. O'B., a woman aged 41, had rheumatoid arthritis involving the fingers, hands, wrists, elbows, knees, ankles and feet. Cinchophen 7½ grains (0.5 Gm.) was given three times a day for four days (total 90 grains, or 5.8 Gm.), after which severe urticaria developed, lasting three days. There was complete relief of the arthritic symptoms with the onset of the urticaria, and the patient remained symptom free for nine weeks. The symptoms then returned, but were less constant and less severe (grade 2) during the next six weeks. The galactose tolerance and the bilirubin excretion test gave positive results. The icterus index was 7.2 before and 8.5 after administration of cinchophen. There was no visible jaundice at any time.

CASE 5.—C. G., a woman aged 50, had rheumatoid arthritis involving the fingers, hands, wrists, knees and feet. Cinchophen 7½ grains (0.5 Gm.) was given three times a day for five days, after which severe urticaria developed and persisted seven days. The arthritic symptoms persisted during the urticaria but there was almost complete cessation (grade 3) of these symptoms for seven weeks after the urticaria subsided. The azorubin S, the hippuric acid and the bilirubin excretion test gave positive results. The icterus index was 8 before and 12.5 after administration of cinchophen. There was no visible jaundice at any time.

COMMENT

In five of nine cases of urticaria following the administration of cinchophen there was some relief from the arthritic symptoms, which was far more striking than that obtained with cinchophen per se. There was reduction and in some cases disappearance of swelling, muscle spasm, fatigue, soreness and stiffness of the joints and other conditions with a marked increase in function. The degree as well as the duration of relief varied in different cases. In some there was complete cessation of symptoms, while in others the relief was only partial. The relief from the arthritic symptoms was in general proportional to the severity and duration of the urticaria. The longest period of relief was five months, the shortest three weeks and the average nine weeks. There was no appreciable increase in the icterus index in four cases, and, although there was an increase in the fifth, it remained in the subicteric stage. The relief obtained in these cases was not due therefore to jaundice. Four patients who did not obtain relief had urticaria as severe as did the five who obtained relief. In case 3 the symptoms were worse during the urticaria, although relief was obtained after the urticaria subsided. In case 5 the pain remained the same during the urticaria but was relieved after it subsided. These observations lead one to conclude that the factor which produces the urticaria may not be the same as that which produces relief of the arthritic symptoms. Cinchophen toxicity apparently involves several chemical changes, and it is possible that the chemical reaction in the four cases of urticaria without relief was not the same as that in the cases in which urticaria was followed by relief of symptoms. The reactions responsible for both urticaria and relief occurred in cases of relief following urticaria, whereas only the chemical reaction responsible for the urticaria occurred in those in which there was no relief of symptoms. In cases 1, 2 and 4 these reactions occurred simultaneously, but in cases 3 and 5 they occurred separately.

6. Grade 1 designates slight relief, grade 2 moderate relief, grade 3 definite relief and grade 4 complete relief.

CONCLUSIONS

1. The evidence obtained in this small series of cases suggests that with cinchophen toxicity there are several definite chemical reactions and that the one which produces relief of the arthritic symptoms during or after urticaria is not the one which produces the cutaneous reaction.

2. Jaundice is not the only means of producing dramatic relief of symptoms in rheumatoid arthritis.

3. The relief from arthritic symptoms following jaundice is not necessarily caused by increased bilirubin alone.

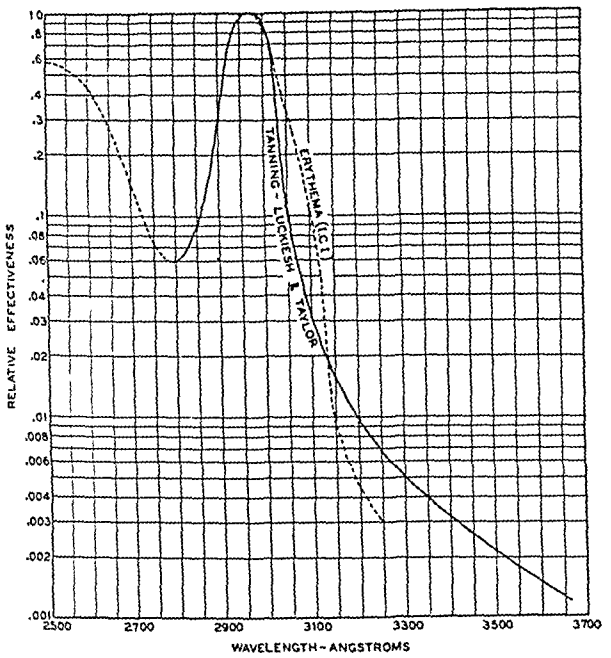
115 East Sixty-First Street.

PRODUCTION OF ERYTHEMA AND TAN BY ULTRAVIOLET ENERGY

MATTHEW LUCKIESH AND A. H. TAYLOR, CLEVELAND
Director and Physicist, Respectively, Lighting Research Laboratory, General Electric Company, Nela Park

The ultraviolet wavelength region from approximately 2,500 to 3,500 angstroms encompasses the wavelengths found to be most valuable in the prevention and cure of rickets, the production of erythema and tan in human skin, the killing of germs, and various therapeutic applications. However, the effectiveness of equal amounts of energy at various wavelengths in this region varies enormously for each of these reactions. Some studies of the relative effectiveness of energy of different wavelengths for some of these reactions have been made, notably for the cure of rickets, the killing of germs and the production of erythema.

Several investigators, including ourselves,[1] have studied the effectiveness of ultraviolet energy in producing erythema, and an "erythemal effectiveness" curve has been tentatively established by combining all the data available.[2] The accepted data for wavelengths longer than 3,150 are of questionable accuracy because the energy of longer wavelengths is relatively low in erythemal effectiveness and available artificial ultraviolet sources are low in energy in the spectral region from 3,150 to 4,000. In therapeutic applications erythema has proved to be a valuable indicator of dosage of ultraviolet; hence it is important to know the relative effectiveness of different wavelengths in its production.



For the foregoing reasons we have extended our previous studies by another research, from which we have established a spectral tanning curve and have extended the spectral erythemal curve in the long wave region. We obtained high energy densities by focusing the image of the arc of an S-1 lamp in quartz or Corex bulb through quartz lenses onto the arm

1. Luckiesh, Matthew; Holladay, L. L., and Taylor, A. H.: Reaction of Untanned Human Skin to Ultraviolet Radiation, J. Optic. Soc. America **20**: 423 (Aug.) 1930.
2. Evaluation of Ultraviolet Radiation, Tr. Illum. Engin. Soc. **30**: 568, 1935.

of the subject, using various glass filters to limit the wavelength region incident on the skin. As a result of exposures of eighteen male subjects, principally between the ages of 25 and 35, we obtained the spectral "tanning effectiveness" curve shown in the accompanying chart. For comparison we also show the "erythemal effectiveness" curve as adopted by the International Commission on Illumination. Our data on tanning apply to the resultant tan as observed from four to ten weeks after exposure, when all erythemal inflammation has disappeared.

Ultraviolet energy in the wavelength region from 2,500 to 2,600 angstroms can cause a strong erythema, visible a few hours after the exposure, but the inflammation subsides and disappears after a few days, leaving little or no tan. We find, however, that the energy of wavelengths longer than approximately 3,300 angstroms, especially that at 3,650 angstroms, produces what appears to be a direct tanning effect. Immediately after an exposure of sufficient intensity and duration the exposed spot appears brownish, approximately the color of tanned skin. The next day the spot is still tanned, with relatively less inflammation than spots exposed to energy of shorter wavelengths.

Although we find that an apparent direct tanning effect with less inflammation can be obtained with the longer wavelengths,

Relative spectral effectiveness of radiant energy in the production of erythema (as adopted by the International Commission on Illumination) and tan (Luckiesh and Taylor).

the energy density and duration of exposure necessary are prohibitive if one desires to become tanned. A much more efficient and effective method is to expose oneself repeatedly to natural or artificial sunlight, making the exposure sufficient to obtain an appreciable erythema.

In order to determine the exposure required to produce a definite tan, visible after two months or more, twelve subjects were exposed to an artificial sunlight lamp (type S-4) at a distance of 2½ feet. Twelve spots on each subject were given exposures graduated in length from two and one-half to ten minutes. The average exposure required to produce a minimum erythema visible one day later was four minutes. The average exposure which produced a minimum tan visible two months after exposure was seven and one-half minutes. Six months after exposure five of the subjects still had spots which were visibly tanned. The ultraviolet rays from this sun lamp are principally in narrow bands at 2,967, 3,022 and 3,130 angstroms. Most of the erythema and tan are produced by the lines at 2,967 and 3,022 angstroms.

Suberythemal doses of ultraviolet rays given three times a week until seven doses were received produced no tan on two persons, but a single exposure of about 70 per cent of the sum of the smaller doses did produce erythema and tan. These results indicate that if tanning is desired the exposures should be long enough to produce some erythema. This is probably true regardless of the type of source, whether sunlight or a sun lamp. Some work done by Dr. H. J. Gerstenberger[3] with which we were in close touch, in which tungsten lamps with ultraviolet transmitting bulbs were used, proved that suberythema exposures or doses of ultraviolet energy can prevent and cure rickets in children. Daily exposures of the order of one-tenth to one-fourth of that required to produce a minimum perceptible erythema were found to be sufficient to bring about recovery.

CONFERENCES ON THERAPY

TREATMENT OF ADDISON'S DISEASE

NOTE.—*These are actual reports, slightly edited, of conferences by the members of the Departments of Pharmacology and of Medicine of Cornell University Medical College and the New York Hospital, with the collaboration of other departments. The questions and discussions involve participation by members of the staff of the college and hospital, students and visitors.*

DR. ADE T. MILHORAT: Dr. Loeb of the College of Physicians and Surgeons of Columbia University will open the discussion.

DR. ROBERT F. LOEB: Thomas Addison in 1849 first pointed out that serious disease of the adrenal capsules was incompatible with life; that was an extraordinarily important observation. In 1855 he published his beautiful monograph on Addison's disease, in which his clinical description, typical of most of the English school of clinicians at that time, is incomparable. In that treatise he also pointed out that little was known of the physiology of the adrenal glands except that they were essential for life, and he felt that perhaps the severity of the disease was more or less proportional to the extent of damage in those structures. From that time our understanding of the functions of the adrenal cortex really did not progress until epinephrine was isolated. Then, quite naturally, that advance aroused more interest in the adrenal glands; it was thought that perhaps the lack of this substance from the medulla might be held responsible for the picture of adrenal insufficiency. However, it soon turned out that the blood pressure could not be maintained in the addisonian patient nor could any particular improvement be brought about by the extensive use of epinephrine. The adrenalectomized animals died despite this type of therapy. Perhaps they died a little more quickly than without any therapy. This was an important negative observation because it definitely established that the factors in the adrenal glands essential to life resided in the cortex.

In 1912 Porges in Vienna first pointed out that patients and animals with adrenal insufficiency show from time to time manifestations of low blood sugar. This was, perhaps, the first demonstration of a specific defect in metabolism in contrast to the general observation that the adrenal cortex was essential for life. Naturally, at that time Porges attributed that defect in carbohydrate metabolism to a disturbance in the adrenal medulla. That interpretation does not appear to be correct today.

Perhaps the next significant step was made by E. K. Marshall in Baltimore, who showed in 1916 that in

3. Gerstenberger, H. J., and Horsch, A. J.: The Cure of Infantile Rickets with Tungsten Filament Radiation, J. A. M. A. **97**:766 (Sept. 12) 1931. Also later results by Dr. Gerstenberger, as yet unpublished.

adrenalectomized animals there was a retention of urea and a decrease in excretion of phenolsulfonphthalein and that death was associated with these manifestations of renal insufficiency. He expressed the idea at that time that perhaps the adrenal cortex had some controlling influence on certain functions of the kidney.

After that the dissection of the physiologic activities of the adrenal cortex progressed rather rapidly. In 1927 Baumann and Kurland showed, in studying the blood of adrenalectomized animals, that a number of changes occurred in addition to the tendency to low blood sugar and to retention of nonprotein nitrogen. They discovered that the blood sodium was low and pointed out that the potassium might be elevated. Then Marine and Baumann in the same year tried various types of replacement therapy and found that their adrenalectomized animals seemed to live longer if they gave solutions of sodium chloride than if they gave other kinds of solution.

Later on, the study of Addison's disease bore out similar facts, namely that the picture of adrenal insufficiency in man (acute adrenal insufficiency) was characterized by dehydration, which had been observed previously, by striking loss of sodium accompanied by a corresponding decrease of chloride and bicarbonate, by an increase in potassium in the blood serum, and by the retention of nonprotein nitrogen, phosphate and sulfate and other substances which are retained in any severe type of renal insufficiency. Also it became evident not only that patients with Addison's disease could have relatively low blood sugar but that they might have severe hypoglycemic reactions, and in recent years we have seen five patients who virtually had hypoglycemic coma at one time or another.

There are some disturbances which appear to be secondary to these fundamental changes. One is the lowering of the basal metabolic rate which usually takes place mostly when the animal or patient is in severe insufficiency. Furthermore there is a decrease in blood flow as well as a decrease in blood volume, which again is perhaps a late manifestation of insufficiency. There are hypochlorhydria, nausea and gastric intolerance, which have been attributed by some to a drop in the chloride ion which accompanies the fall in the blood sodium. There is also hypotension, which usually is present to some degree even when the electrolyte pattern of the blood is entirely normal but which is possibly related to electrolyte and water disturbances.

In addition to the fundamental changes mentioned there is another which is probably also primary in nature; that is the feeling of weakness and lassitude which is the chief complaint of the vast majority of patients with adrenal insufficiency and which is the striking objective manifestation of animals in adrenal insufficiency. This may prove to be entirely dependent on the trouble with salt, water and sugar metabolism. The mechanism of pigmentation which should be considered as primary in nature is totally obscure.

These are some of the changes which follow the destruction of the adrenal cortex in man. Naturally the question arises as to how these errors in metabolism may be corrected. It is interesting not only from a physiologic standpoint but also from the point of view of the patient with Addison's disease. In the last twelve years, extracts of the adrenal cortex have been developed. I might add, however, that Sir William Osler was the first to use an extract of the adrenal cortex in the treatment of a patient. In 1896 Sir William made a glycerin extract of thirty hog adrenal glands and administered this to a man who had Addison's disease. He thought there was some improvement, but the patient died of miliary tuberculosis, for which Sir William was not entirely responsible!

In 1927 Rogoff and also Hartman independently made extracts of adrenal glands, which they felt definitely prolonged the life of adrenalectomized animals and perhaps had some value in the treatment of Addison's disease. In 1929 Pfiffner and Swingle made an alcoholic extract of the adrenal glands which seemed to have considerably more potency. That was heralded as being the turning point in the treatment of a hitherto fatal disease, and the early results from the use of adrenal cortex extract were most dramatic. I think that the enthusiasm died down fairly promptly and it is now apparent that many of the results which were obtained at that time with the use of the adrenal cortex extract might more properly be attributed to the replacement of salt and water in those individuals who were in a state of adrenal insufficiency. The role of the extract was probably not highly significant.

We now know that the dosage of commercial extracts required to maintain an adrenalectomized dog in normal health without salt added to its diet is of an order of magnitude such that if the pharmacologists permitted translation to man, which is probably not permissible, it would take perhaps 50 cc. a day to maintain a large adrenalectomized human being—perhaps even more under certain conditions.

SOME FEATURES OF TREATMENT

The treatment of Addison's disease, as is true in other metabolic diseases, should be directed first toward the correction of the physiologic disturbances which result primarily from the absence of the adrenal cortex. The consideration of the adrenal medulla in this connection does not seem to be important. The next important consideration is that of the specific replacement of adrenal cortical hormones lacking in adrenal insufficiency. The third principle in the treatment of Addison's disease consists of avoiding those factors which are known to intensify the disease picture.

To me these principles are much like those involved in the treatment of diabetes; curiously enough there are many analogies between the treatment of diabetes and the treatment of Addison's disease in man.

In the mild case in which adrenal insufficiency is well compensated, that is, one in which the physiologic disturbances which we can measure are relatively slight, the replacement of the sodium ion, by merely feeding salt, will help the situation. In other words, just correcting this one physiologic disturbance may prove adequate. On the other hand, in the presence of severe insufficiency this measure does not succeed, and it is necessary to add the factor of hormone replacement as far as this is possible.

In treating a patient with Addison's disease, keep in mind that even though he may have relatively mild adrenal insufficiency he, like the patient with diabetes, is more or less perched on the brink of a physiologic volcano. An acute infection, a trauma associated with pain, a surgical procedure or indiscretions in diet will frequently shift the picture quickly from one of compensated adrenal insufficiency to one of a severe adrenal crisis. In the adrenal crisis treatment must be just as promptly and just as actively instituted as in the case of diabetic acidosis, in which neglect or procrastination usually results in death—needlessly I might add.

What else can we do about [illegible] disturbances which are present in [illegible]? First, diet. Keep in mind that we are dealing primarily with a chronic disease, often tuberculous in origin. I think that the most important consideration in the diet is the maintenance of the patient's nutrition. If the patient's nutrition can be maintained, consider secondarily the theoretical importance of the constituents of that diet. We know, as I have mentioned, that potassium is retained in the body in adrenal insufficiency. It is retained partly because of a disturbance in the ability of the kidney to excrete potassium. It is retained probably also because there is a curious alteration of flow of potassium to the cells. That is nicely demonstrable in recent experiments with desoxycorticosterone acetate, which effects an increase in potassium excretion far greater than could be explained on the basis of loss from extracellular fluid. So there is the disturbance in potassium metabolism, and we know that when one does not excrete the potassium ion (whether one does not excrete it because one has severe renal insufficiency or because one has adrenal insufficiency) if you inject potassium intravenously a fatal elevation in level develops much more readily than in a normal individual. We know that adding several grams of potassium to the diet of an adrenalectomized dog makes it necessary to give either large amounts of sodium chloride or larger amounts of cortical extract, or both, to maintain life. With these facts in mind, and because Wilder and Allers pointed out that the ingestion of a good deal of potassium ion causes a further loss of the sodium ion from the body, the Mayo Clinic developed a low potassium diet, which has a sound theoretical basis. Unfortunately, if there is any ubiquitous ion in our food it is the potassium ion. It is the normal constituent of cells, and to make a potassium-free diet we would theoretically have to construct a diet without cells.

To avoid the usual amounts of potassium in the diet certain foods are restricted, namely dried fruits and dried vegetables, concentrated sauces, condiments, unpolished cereals, large amounts of meat and soups, which are really nothing but potassium juice with a little sodium added. In addition to limiting these foodstuffs at the Mayo Clinic they advise that meats and vegetables be prepared by cutting them into tiny pieces and cooking them in six to eight volumes of water in Patapar bags and then serving them to the patient. But I find that most of our patients are either fussy about their food and do not take it very well in that form or perhaps we have not developed the appropriate culinary arts. Anyway, I think that if a patient can be induced to eat a truly low potassium diet there is a distinct theoretical and also practical advantage in it. However, if you have to choose between having your patient lose weight or eat 2 or 3 Gm. of extra potassium a day, I would recommend that you let him have the potassium and not be in the situation that the Germans used to ascribe to us in relation to the treatment of diabetes in the days of the Allen regimen, when we used to fast them for two weeks. Isn't that right, Dr. Du Bois?

DR. EUGENE F. DU BOIS: Yes.

DR. LOEB: As the Germans used to say, "You in America stick out your chests and pride yourselves because your patients die sugar free." There was something in their point of view.

The carbohydrates of the diet must also be considered. As I have said, patients tend to have hypoglycemia, and I warn you to be on your guard. A patient with Addison's disease, one perhaps with focal neurologic signs or a confusional state, is frequently the subject of severe hypoglycemia. Perhaps the best way to avoid it is to ask patients to eat small supplementary amounts of candy or sugar between their meals and when they go to bed. I am not sure whether this course has really any particular virtue for the patient, because we know that with people who have a tendency to hypoglycemia the blood sugar may decline abruptly during the sleeping hours after carbohydrate administration for the day has stopped. Still we do encourage patients to ingest carbohydrate frequently but I cannot say that we have seen fewer hypoglycemic episodes by virtue of frequent carbohydrate feeding.

To summarize the diet: Calories come first; low potassium diet, if possible, next; and finally adequate carbohydrate.

The role of salt, as I have mentioned, appears to be of considerable importance in the treatment of Addison's disease as it is in the adrenalectomized animal. We know that completely adrenalectomized animals may be maintained without any other factor (no cortical extract) for many months if just given large amounts of salt, sodium chloride or sodium citrate. So also in patients we see many severe crises which are completely relieved by the administration of large amounts of sodium chloride in water without the use of cortical extract. We see this so frequently that we find it impossible to attribute much value to cortical extract in the doses usually given. Most patients with Addison's disease seem to get along for a number of years with no medication other than salt in doses of from 10 to 20 Gm. a day in addition to their meals. Many of them take it in the form of 1 Gm. tablets. They put their ration in their pockets during the day and take one perhaps every hour. Other patients find it more palatable to drink a large volume of salt solution. Very few are able to tolerate capsules.

There is one feature of sodium administration which has been greatly stressed by a number of workers: We know that with the sodium ion decreasing in the blood by virtue of its increased excretion through the kidneys in adrenal insufficiency there is frequently also a drop in the bicarbonate ion as well as the chloride ion, and because of that Wilder and Allers have felt that one should administer a sodium salt without a fixed acid radical in addition to sodium chloride. For that reason they advise the use of sodium citrate or sodium bicarbonate as well as sodium chloride. With this in view I summarized a series of twenty of our patients who were treated with salt alone. The average normal sodium concentration of the serum is 140 milliequivalents per liter, the chloride being about 104 milliequivalents and the bicarbonate being about 26 milliequivalents. The average sodium on admission in the series of addisonian patients was 125.1, the average chloride was 92 and the average bicarbonate was 23 milliequivalents per liter. After these twenty patients had been treated with nothing but sodium chloride, the average sodium at the end of treatment was 138.5, the chloride was 104.1 and the bicarbonate was 25 milliequivalents. In other words, just by administration of sodium chloride the kidney selectively retained the proper anion to restore the normal electrolyte pattern of the blood as it does in the treatment of diabetic acidosis. We know that with the administration of sodium chloride the body will save base, build up the bicarbonate and excrete the excess chloride. Conse-

quently in adrenal insufficiency I do not think there is any need for the administration of the sodium citrate or bicarbonate, but I can see no harm in it.

Finally, a few words about the use of cortical extract. I have already intimated that certain commercial cortical extracts in doses of from 5 to 10 cc. a day have no definite objective physiologic effect. Patients often say they feel better, but they say they feel better with so many things that I do not believe one can ascribe much significance to that statement. I think it is, on the other hand, not to be denied that a little cortical extract must be better than none. However, a dose of 10 cc. a day costs about $3, and if you cannot demonstrate any physiologic effect from it in your patient I am not sure that it is a justified expenditure. The same applies to the treatment of crises; unless you use large amounts you are not doing anything at all significant. I think it is fair in the treatment of the crisis to give intravenously about 4,000 cc. of salt solution with 5 per cent dextrose in the course of twenty-four hours and to add to that from 40 to 50 cc. of cortical extract, and then if the patient is not doing well perhaps to give from 10 to 15 cc. intravenously or intramuscularly at six hour intervals in addition. Thorn has shown that extract in those amounts will cause retention of sodium and an excess excretion of potassium in normal subjects and in addisonian patients, so that we know that amount may produce some effect.

As I have said, I have had this skepticism of the therapeutic value of extract given in the usual dosage. In the past few months, as you probably know, Reichstein has not only isolated from adrenal glands but synthesized desoxycorticosterone acetate and we have had our first chance at a clinical trial in the past few weeks. I must say that the results are both dramatic and encouraging. In one case the administration of 50, 50, 25, 25, 25 and 25 mg. a day,[1] respectively, over a period of six days caused, first, an increase in plasma volume of 15 per cent, an increase in interstitial fluid, if that is what we measure with the thiocyanate method, of about 15 per cent, a gain in weight, a marked retention of sodium and of chloride, and a doubling of the excretion of potassium ion. That was a result of the first two days' treatment in a patient who was stabilized on a metabolic regimen and whose sodium level was stabilized at 132 milliequivalents. Following this initial increase in fluid volume there was an increase in the sodium concentration in the blood to normal, a fall in potassium to normal and a striking drop in the level of nonprotein nitrogen, and the patient showed striking subjective improvement at the end of these six days. Withdrawal of the desoxycorticosterone resulted in a reversal of this process: first a loss of weight, with a loss of sodium chloride, and secondarily a drop in concentration with some rise in the other constituents. Readministration of the drug, then in doses of just 25 mg. a day, again reversed the process. So we know that in that dosage this substance had a striking effect in a man with adrenal insufficiency. Whether it has any effects on carbohydrate metabolism in man is not certain, but if we had to hazard a guess it would be in the affirmative. Whether it has any effect on pigmentation likewise we do not know. Whether it has any effect on peripheral vascular tone we also do not know. Those questions lie for the future to answer, but I will say that we have at last something which is sufficiently potent to convince the skeptic.

1. This material was furnished by the laboratories of Roche-Organon, Inc.

DR. EPHRAIM SHORR: Dr. Loeb has covered the ground so thoroughly that there remains little for me to do except to illustrate, by means of a patient with Addison's disease, those principles of treatment which he has laid down, so largely as a result of his own fundamental work in this field. This patient will permit you to see the phenomena which are diagnostic of the condition. His history is that of weakness of about six months' duration prior to his admission in September 1938. The weakness was progressive with progressive pigmentation of the skin, including mucous membranes of the mouth and tongue, a hypotension on admission of 87 mm. systolic and 67 diastolic, and gastrointestinal symptoms such as anorexia and postprandial distress, with a moderate loss of weight. He was admitted in considerable distress and has since been studied by Dr. Harrison of the Department of Pediatrics, and myself. We have kept a record of his blood pressure taken at frequent intervals and we have results of electrolyte studies on urine and blood during the course of his stay. On admission, in view of his unsatisfactory condition, we deemed it necessary to administer large amounts of sodium chloride and sodium citrate intravenously. There was a short, stormy period until our efforts in this direction, combined with a cortical hormone preparation (Upjohn), finally succeeded in improving his condition. With this therapy the hypotension was succeeded by blood pressures of approximately 120/80. The symptomatic relief was accompanied by a reversal of the electrolyte failure which he presented on admission. His chloride excretion in the urine was greater than his intake. With these therapeutic measures he finally came into electrolyte balance. The amount of cortical extract necessary to achieve this balance was 20 cc. daily, given in two doses of 10 cc. Blood urea, initially elevated, also returned to normal. Gastrointestinal difficulties disappeared and his muscular strength improved sufficiently to enable him to walk about the wards and to climb two flights of stairs.

The dietary regimen which has since been followed has in general adhered to the principles laid down by Dr. Loeb. As pointed out, it is not too easy in the face of the capricious appetites of these patients to keep the potassium content of the diet at the low figures recommended by the Mayo group. We have succeeded in making a diet palatable for him which contains about 3.5 Gm. of potassium a day. The salt content of the diet has been in the neighborhood of 8 or 10 Gm. a day. He cannot tolerate salt in tablet form and this is about as much as he can take with comfort in his food. We should prefer him to take more but are quite satisfied with this present diet, aided by what appears to be a potent cortical extract.

A second point that Dr. Loeb has mentioned as of assistance in diagnosing the presence of Addison's disease has been the effect of the withdrawal of salt on the electrolyte picture. In this patient the effects of the withdrawal of cortical hormone have been striking and characteristic of true Addison's disease. On a number of occasions the cortical hormone has been diminished. Within three days of reducing the cortical hormone from 20 cc. a day to 10 cc. a day, electrolyte failure occurred, with a return of all of the symptoms of the disease. The chloride in the blood fell from 97 milliequivalents to 91 milliequivalents, and the urinary chlorides rose until a negative balance replaced the positive balance in which he was, prior to withdrawal.

During this time the chloride intake was maintained at a constant level. With resumption of the cortical extract in the amounts of 20 cc. a day, these figures again returned to normal. I think it is apparent from this effect that the cortical extract is genuinely effective in this case.

As to the general handling of the case, we are confronted with the problem of the etiologic factor, which is tuberculosis. The involvement is apparently confined to the kidneys and adrenals. The urinary sediment has been found positive for tubercle bacilli by the guinea pig test. The chest is still entirely free of tuberculous lesions, as shown by x-ray examination.

An immediate problem now confronts us. He is febrile and has a severe tonsillitis. With this tonsillitis, which has been of about twelve hours' duration, an unwelcome change in his symptoms has occurred. In addition to the weakness he has become low in spirits. Depression has been a very striking phenomenon throughout in this case and has always been exaggerated during the periods when the hormone was reduced or withdrawn.

The presence of an infection of this sort complicates the treatment of Addison's disease and makes it much more difficult, just as infection in the diabetic greatly increases the severity of the disease and the resistance to insulin. We can anticipate that within the next few days more heroic measures may be necessary to help the patient tide over his infection. It will be of interest to see whether electrolyte studies will indicate that the formerly adequate dosage of cortical hormone will now prove inadequate, just as in a diabetic patient with infection the previous dosage with insulin generally needs to be increased in infection.

DISCUSSION

DR. HARRY GOLD: What were the blood sugar and the blood urea of this patient?

DR. SHORR: On admission the blood urea was elevated, but with therapy it has come to normal limits. In fact, during periods of diminution in cortical extract therapy we have had electrolyte failure without any increase above normal of blood urea. The sugar on admission when he was quite severely ill was 92 mg. per hundred cubic centimeters, which with the method we use here is a high normal.

DR. JANET TRAVELL: I should like to ask Dr. Loeb about the completely adrenalectomized dogs that were maintained on a high sodium chloride intake. Did they also have the reduction in the potassium intake?

DR. LOEB: As I said, Allers and Harrop both independently carried out these studies, and their dogs were on a mixed diet. If you introduce a meat diet, which is a pretty high potassium diet, it becomes more difficult.

DR. TRAVELL: You can maintain them though if you increase the amount of salt?

DR. LOEB: Yes, but I believe Dr. Harrop found it necessary to introduce salt by tube because the salt requirement was so high. There is one thing I should like to emphasize: I do not think the problem with adrenal insufficiency is solved even with desoxycorticosterone. I think you may have seen a paper in the last issue of the *Journal of Clinical Investigation* by Willson and Sunderman. They pointed out that just the withdrawal of water in the presence of salt administration may precipitate a picture of shock in which the sodium concentration of the blood approaches normal. We have had six patients who have died classic addisonian deaths with peripheral cyanosis, hypotension, the whole clinical picture but with a perfectly normal electrolyte pattern in their blood, with the exception of dehydration. Whether or not there will turn out to be a peripheral vascular disorder similar to that seen in histamine shock, in the picture of adrenal insufficiency, and whether this will be controlled by this one cortical hormone I think is an open question.

DR. SHORR: Have you seen the reports in the *Lancet* of the uses of desoxycorticosterone in England by Levy-Simpson?

DR. LOEB: He reported two cases, but I did not feel that the data which he had presented were particularly convincing from the chemical standpoint.

DR. SHORR: The intramuscular mode of administration was employed, which apparently in some of the cases was associated with painful swellings and had to be discontinued.

DR. LOEB: We gave our product subcutaneously, and it was absolutely painless.

DR. SHORR: Capsules also were implanted.

DR. LOEB: Which is also being done by Dr. Thorn in Baltimore with apparently striking success.

DR. MCKEEN CATTELL: I trust the synthetic material will be more readily obtainable and less expensive.

DR. SHORR: Have you had any experience with the oral administration of any cortical hormone preparation?

DR. LOEB: I have seen a patient, who could afford it I might add, take from 25 to 60 cc. of cortical extract a day by mouth and I think 10 or 15 cc. parenterally twice a week go into a typical crisis and then with the administration of salt and more cortical extract come out of it. I was not impressed with the differences in this patient when he was taking large or smaller amounts. Pfiffner years ago pointed out in his calibrated dogs that he found cortical extract more or less effective by mouth. He felt that the necessary dosage was something like 10 to 1 in relation to parenteral administration. Thorn, in his article in *Endocrinology*, intimates that the ratio is probably 3 or 4 to 1. I may be hyperskeptical about the whole thing, as I am not greatly impressed. One thing to be kept in mind in attempting to evaluate therapy is that in this disease, as in other diseases, patients occasionally lived for many years without the advantages of modern therapy. Bramwell reported that a patient with Addison's disease certainly went in and out of crises all by himself, without salt and without extracts. As soon as we have some therapeutic agent that we can give with a hypodermic, post hoc reasoning becomes an almost insuperable temptation.

DR. SHORR: It seems reasonable to anticipate that if one could give enough of the synthetic preparation it could be absorbed by mouth in therapeutic amounts. The chemical composition is so close to that of the sex hormones, which are very well absorbed in the mouth, that we may expect the cortical hormone to be absorbed well also.

DR. LOEB: I think there is no question at all but that our troubles with cortical extract are essentially quantitative in nature as far as the salt and water disturbances are concerned and possibly as far as carbohydrate disturbances are concerned. By this I mean that, if it were possible to administer sufficiently large amounts, striking effects would be obtained. Whether salt, water

and carbohydrate disturbances are going to prove to be the whole story is another matter. I rather doubt it.

DR. H. B. RICHARDSON: What active preparations of adrenal cortical hormone are available on the market?

DR. LOEB: I am sure that the Upjohn, Wilson, Organon and the Parke-Davis material are all potent in animals although there are no comparative assays available. But again I think the problem concerns the amount of material which you can administer to a patient a day. Desoxycorticosterone acetate is so sparingly soluble it has to be given in sesame oil, which is a disadvantage as far as rapidity of absorption is concerned when compared with the available cortical extracts which can be given intravenously. I have asked the chemists about the possibility of shaking desoxycorticosterone into serum to have it available for emergency use, because the slow absorption delays the effects, and in a crisis the present preparation would begin its action too late.

DR. SHORR: It would look as if the Upjohn preparation, which is the only one we have used systematically in this patient, has been effective.

STUDENT: I have heard that in patients with severe burns you sometimes find at autopsy hemorrhage in the adrenal cortex. I was wondering whether those patients when recovered from their burns stood any chance of developing the Addison syndrome.

DR. LOEB: I never heard of one subsequently developing Addison's disease. I should think it unlikely because, whereas part of the picture of shock may be due to an adrenal hemorrhage, exudation of serum from the surface and possibly absorption of necrotic tissue products are probably the chief factors.

DR. GOLD: What are your minimum requirements for the diagnosis of Addison's disease, and are there any conditions other than frank Addison's disease in which cortical hormone is useful?

DR. LOEB: That is a large question. I think that the withdrawal of salt from the diet gives one as good an idea of whether or not clinically significant Addison's disease is present as any test I know. If symptoms of the disease are not strikingly accentuated by this procedure in the course of seven days and if there is no decrease in blood sodium beyond 4 milliequivalents per liter, the diagnosis would indeed seem doubtful. Recently Cutler, Power and Wilder have devised another diagnostic test but I have had no experience with it. Salt withdrawal should not be undertaken in an outspoken case without great caution and the diagnostic test should be undertaken only with the patient under observation in a hospital.

If a patient can tolerate withdrawal of salt for seven days I feel it is unwise to administer cortical hormone. I think Ingle's work is very significant, and I think we may be in trouble if we start using the hormone indiscriminately. Ingle has shown that in the normal rat moderately large doses of cortical extract cause striking atrophy of the adrenal cortex. I feel that in the prolonged treatment of "tired women" and the like the use of cortical extract in significant amounts may prove dangerous. I think it is possible that it may be worth while to study the effect of cortical hormone when it is available in large amounts in the state of shock and in certain other conditions in which there are peripheral vascular disturbances, but I am loath to use it over long periods of time, as I said, in any one who has not well established Addison's disease.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. H. A. CARTER, Secretary.

SUPREME MODEL SHORT WAVE DIATHERMY NOT ACCEPTABLE

Manufacturer: Scientific Diathermy Corporation, 200 West Thirty-Fourth Street, New York.

An apparatus recently placed on the market is the "Supreme Model Short Wave Diathermy." It is sold to the public and, according to the advertising copy referred to the Council, solicitations are made to radio jobbers for agencies. It is a portable apparatus in a case with a carrying handle. When the front cover is removed there is seen a knob for control, an automatic timer dial and an electric meter. It is of light construction and is equipped with one thermionic tube. The electrodes consist of two oblong pads with a thin rubber coating.

This device is marketed to the public by means of advertising in newspapers under the heading "Arthritic and Rheumatic Pains" and announcing "Free Demonstration." According to the advertising, lay salesmen will demonstrate this unit at the home of any one interested. The advertising pamphlet entitled "Radiant Health from Radio Waves" implies that short wave diathermy is indicated in the following diseases: arthritis, rheumatism, circulatory disturbances, sciatica, neuritis, sinus infection, hay fever, lung pathology (except tuberculosis), prostatitis, colds and general injury. Rapid relief and recovery are cited in some instances. The pamphlet also contains such absurd statements as "Fight off old age! Use short-wave radiothermy!" "With this amazing new invention, painless days are here at last!" "Radio-waves smooth away your pains. Relief is quick and lasting—" "Especially those who could ill afford costly professional treatments, welcome the short-wave machines with heart-felt thanks."

One advertising sheet for the attention of radio jobbers and dealers is quoted:

> "Here it is . . . the Biggest News that has come to the Radio Industry in years! Radio Jobbers, Radio Dealers, Radio Servicemen all have watched the Receiver Sales curve DIP . . . they've watched diminishing sales and the smaller profits . . . but today a real opportunity exists in this brand new field of Radio-Thermy!
>
> "The Scientific Diathermy Supreme Model illustrated here lists for $149.50 with regular discounts to Dealer and Jobber. It's easy to demonstrate and as easy to sell!
>
> "Every home is a prospect for this modern miracle, which is recommended for the relief of Arthritis, Rheumatism, Lumbago, Common Colds, and many other ailments.
>
> "If you're looking for a NEW SOURCE OF PROFITS IN 1939 . . . Swing to Radiothermy and you'll swing into big money!"

Although no specific therapeutic agency except heat is cited by which the diseases named are benefited, there is the implication that something different and wonderful is achieved by short wave diathermy, as for example "modern miracle." In the pamphlet there appears to be an attempt to give a great scientific aura to short wave diathermy by reproducing headlines alone, or excerpts of newspaper stories or articles on scientific subjects. In some instances these concern other kinds of therapy. One article quoted from dealt with the use of electrical cautery devices, another with so-called electric massage, and others with fever-inducing apparatus.

Finally, apparent duplicates of testimonials by lay individuals were reproduced and accounts were given in the advertising of the frequent demonstation of the apparatus by laymen to others for the relief of many kinds of ailments. The advertising is typical in general tone of that for common nostrums meant to appeal to the uninformed.

In the opinion of the Council on Physical Therapy, the Scientific Diathermy Corporation is practicing methods that are detrimental to the public interest and rational therapeutics. Sales methods which promote the practice of self treatment of disease by those unqualified to practice medicine appeal to the public with persuasions which are unscientific and may harmfully enhance a feeling of false security on the part of the public.

Such wanton disregard of the best interest of the public probably will not be tolerated after the new food and drug act becomes operative.

In view of the foregoing report, the Council on Physical Therapy voted not to include the Supreme Model Short Wave Diathermy in its list of accepted devices.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

PAUL NICHOLAS LEECH, Secretary.

ACIFORM II NOT ACCEPTABLE FOR N. N. R.

Aciform II (Aciform Corp.) is a preparation stated to contain in each cubic centimeter 0.0018 Gm. of formic acid, 0.004 Gm. of iodine, 0.0002 Gm. of sulfur, 0.0001 cc. of "terpene (camphene from Borneol camphor)" and 0.055 cc. of 95 per cent alcohol. In Germany the term "Aciform" is used for two preparations, "Aciform I" being a combination of formic acid, iodine plus "terpenes," and "Aciform II" containing formic acid, iodine, sulfur and a "terpene." The preparation has not been presented by the firm for the Council's consideration.

The advertising distributed by the firm since 1938 has announced this product as a new parenteral therapeutic agent for the treatment of "Acute and Chronic Arthritis, Lumbago, Sciatica, Neuralgia, and the associated Neuro-Muscular Disturbances." It is claimed that "Aciform II" is the result of "many years of laboratory research, and of clinical study in the fields of the physio-chemistry and chemo-therapy of inflammatory conditions in the human body." Only two reports on the results of these investigations have appeared in the scientific literature (Erlsbach, O., and Burger, A.: *Med. Klin.* **33**:1605 [Nov. 26] 1937, and Mayers, L. H., and Livingston, S. K.: The Treatment of Arthritis and Associated Conditions, *Indust. Med.* **8**:75 [Feb.] 1939). These reports are insufficient to support the claim that "Aciform II . . . has been subjected to the most critical tests in the leading medical centers of Europe in the treatment of the indicated diseases, with a record of successes that is reported as falling nothing short of the dramatic" and that this therapy ". . . is so spectacular, that without the unassailable evidence that is constantly being compiled from the experience of clinicians of highest standing, would be well nigh unbelievable."

The following description of the pharmacodynamics of "Aciform II" therapy could not be confirmed despite the availability of a well equipped medical library:

"The inflammation produced in the tissues by acute lumbago, sciatica, and acute and chronic arthritis is marked by certain histological changes. These include stasis, changes in the blood volume and ionization, and alterations in the small blood vessel walls. In addition there is an upset in the osmotic balance, and local tissue edema from the various exudations. The principle of ACIFORM therapy is the restoration of normal circulation, the elimination of toxins resulting from tissue damage, and the production of lymph flow with the resultant removal of tissue edema. This permits cellular repair, re-growth, and return to normal function."

The writer of the advertising also draws on the time-worn phrase "synergistic action of the components," which has been much used to give a scientific color to dubious therapeutic claims. The following quotation from the advertising is a naive admission of the lack of competent evidence for the therapeutic value of Aciform II:

"How many forms of useful therapy do you know that are being widely and successfully employed, that cannot be regimented into the hard and fast grooves of therapeutic theory as laid down in the text books and by accepted medical authorities.

You are, without a doubt, employing some of them for the benefit of your patients. You know they work, regardless of the 'why' and of generally accepted theory."

This admission is repeated in the recent article by Mayers and Livingston, of which reprints have been mailed widely to physicians. In this report it is stated that:

"The mode of action of the new preparation is admittedly obscure and empiric. It is thought that the components in the presence of the terpene are diffused and disseminated in the tissues in an action comparable to that evidenced in greater molecular dissociation. The therapeutic principle of the parenteral acid therapy is *presumably* [italics ours] the restoration of normal circulation in an affected part, the elimination of toxins resulting from tissue damage, and the production of lymph flow with the resultant removal of tissue edema. Such action permits cellular repair and a return to a more normal function. This new therapy has the advantage of producing such results immediately and safely by injection into the involved and adjoining areas."

The literature has been surveyed extensively, but little has been found that would support the claims advanced for "Aciform II" therapy. In Martindale's Extra-Pharmacopeia, 1936 (p. 36), it is stated that formic acid injections are of value in rheumatic disorders. The mode of action is claimed to be similar to that of cantharides in giving tone to muscles and restraining muscular tremors. The exact relationship between improving muscle tone and clearing up an infected joint is not discussed.

Formic acid therapy, like numerous other remedies promoted for "lumbago," "sciatica," and so on, can be dismissed from the armamentarium of pharmaceutic preparations without the slightest chance of depriving the sufferer from these conditions of any possible relief.

The Council declared Aciform II (Aciform Corp.) unacceptable for inclusion in New and Nonofficial Remedies because it is a preparation of unscientific composition marketed under a coined proprietary name with exaggerated and misleading claims of therapeutic value.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

ASTORIA BRAND FREE-FROM-PRESERVATIVE GREEN CHERRIES

Manufacturer.—Fruit Products Corporation, Belleville, N. J.

Description.—Bottled, peppermint flavored and artificially colored preserved green cherries; for use in decorating and flavoring foods. No artificial preservatives are used; oil of peppermint, citric acid, U. S. Department of Agriculture certified color and a small amount of alcohol are added. The alcohol is used to dissolve the flavoring.

Manufacture.—The method of manufacture is the same as that described for Astoria Brand Free-From-Preservative Cherries (red) (THE JOURNAL, Sept. 17, 1938, p. 1101).

Analysis (submitted by manufacturer).—The manufacturer reports that the proximate composition of these cherries is essentially the same as for Astoria Brand Free-From-Preservative Cherries (red) (THE JOURNAL, Sept. 17, 1938, p. 1101).

Calories.—1.2 per gram; 34 per ounce.

HOSTESS NEW BLEND BRAND SALAD DRESSING

Manufacturer.—Hostess Products Corporation, Long Island, N. Y.

Description.—Salad dressing containing cottonseed oil, water, cider vinegar, distilled vinegar, sugar, fresh egg yolk, corn starch, salt, tapioca and oil of mustard seasoning.

Manufacture.—Egg yolk, salt, sugar and spices in definite proportions are beaten together at high speed; oil is beaten in, then water and vinegar. The emulsified mixture is combined with formula proportions of a starch paste containing tapioca, corn starch, vinegar, sugar and water, and automatically filled into glass jars.

Analysis (submitted by manufacturer).—Moisture 41.1%, total solids 58.9%, ash 1.8%, sodium chloride (NaCl) 1.4%, fat (ether extract) 42.6%, protein (N × 6.25) 0.9%, reducing sugars as invert sugar 5.5%, total carbohydrate including crude fiber (by difference) 12.5%, titratable acidity as acetic acid 1.0%, lecithin phosphoric acid (P_2O_5) 0.047%, total phosphoric acid (P_2O_5) 0.122%, estimated egg yolk solids 2.6%, estimated egg yolks 5.3%.

Calories.—4.4 per gram; 125 per ounce.

UNSATURATED FATTY ACIDS IN NUTRITION

Since the consideration in THE JOURNAL of the general thesis of the existence of indispensable fatty acids in nutrition,[1] information has been obtained which makes it possible to evaluate more accurately the function of these acids. The earlier work clearly established that the rat does not thrive on diets rigidly devoid of fat but acquires a characteristic deficiency disease. Although the many symptoms of this experimental condition were alleviated by giving a few milligrams of fat to the rats, it was established that the need of the animals was not for fat in general but for certain specific unsaturated fatty acids. The administration of either linoleic or linolenic acid resulted in a cure of the deficiency disease. Moreover, the ineffectiveness of other unsaturated fatty acids and of saturated fatty acids in curing the symptoms led to the suggestion that linoleic and linolenic acids cannot be synthesized in appreciable quantities by warm blooded animals. These fatty acids, therefore, become indispensable for living organisms and assume a position similar to that of certain amino acids, vitamins and minerals as a necessary constituent of a complete diet. The presence of at least one of the two fatty acids is required to promote the normal well-being of experimental animals.

Ample confirmation of the thesis of indispensable fatty acids has been presented, and investigators have expanded the original observations to include the study of other untested fatty acids in an effort to evolve some general conclusions as to why certain fatty acids are capable of curing the "fat deficiency" syndrome while others are not. Arachidonic acid has recently been added to the list of acids capable of alleviating the deficiency symptoms;[2] this fatty acid, administered as the methyl ester, was shown to be approximately three times more effective as a curative agent than is linoleic acid. Other types of unsaturated fatty acids tested were negative with respect to curative power. From a consideration of the results, certain features of a fatty acid molecule seem to be required in order that the substance may be capable of alleviating the fat-deficiency symptoms: at least two double bonds are necessary (linoleic, linolenic and arachidonic acids) and these double bonds must occupy certain positions (positions 9:10 and 12:13, as in the aforementioned acids). Evidently the third and fourth double bonds, as present in linolenic and arachidonic acids respectively, cannot be of any importance because linoleic acid, with two double bonds, is as effective as linolenic acid with three. The fact that arachidonic acid is superior as a curative agent to any other substance thus far tested leads to the tentative hypothesis that the need of the animal body is primarily for this acid. Under these circumstances the other curative fatty acids may be regarded as beneficial by virtue of their conversion to arachidonic acid in the body.

Detailed studies of the essential fatty acids in their relation to the fat-deficiency disease of rats have been recently reported[3] by investigators at the Lister Institute in London. These authors have attempted to compare quantitatively the ability of certain fatty acids to alleviate the principal symptoms of the fat-deficiency disease. In addition, some explanation was sought for the specific curative action of certain fatty acids. Although the latter goal has not been attained, the quantitative nature of the investigation, together with the large amount of data presented, mark these contributions as noteworthy. The English investigators employed resumption of gain in body weight and healing of skin lesions as criteria of the efficacy of certain materials to supplement the fat-free diet. It was demonstrated that methyl linoleate was much more potent and lasting in action than methyl linolenate; the latter was approximately one sixth as potent as the former. A study was also made of the ability of various oxidation products of linoleic acid and linolenic acid to alleviate the deficiency symptoms. It seemed possible that an oxidation product might be formed as a further stage in some metabolic process and that these products might be of some significance in elucidating the part played in metabolism by these unsaturated fatty acids. However, the oxidation products that were tested failed to benefit cutaneous lesions and were ineffective in prompting increase in weight. However, a fatty acid containing twenty-two carbon atoms and six double bonds, isolated from cod liver oil, was found to be potent in promoting increase in weight but to have little or no action in curing lesions of the skin. This leads to the interesting conclusion that the capacity of unsaturated fatty acids to supplement a fat-free diet in promoting gain in body weight is not necessarily associated with ability to heal skin lesions.

2. Turpeinen, Osmo: J. Nutrition **15**: 351 (April) 1938.
3. Hume, Eleanor M.; Nunn, L. C. A.; Smedley-Maclean, Ida, and Smith, Hannah H.: Biochem. J. **32**: 2162 (Dec.) 1938.

As another step in elucidating the role of the essential fatty acids in metabolism, the Lister group [4] has also determined the nature of the fatty acids stored when the rats were kept on a fat-deficient diet and has studied the alterations which occurred in these stored fatty acids when the curative acids were fed. The livers of the animals fed a fat-free diet contained no fatty acids with four or more double bonds. When small doses of methyl linoleate supplemented the fat-free diet, however, fatty acids of four or more double bonds were deposited in the liver fat. Similar results were obtained when methyl linolenate was used as the dietary adjunct. From these thorough investigations it appears that, whereas the essential linoleic or linolenic acids may have some direct effect on the skin, their main function is to supply material from which higher and more unsaturated fatty acids may be synthesized. Moreover, since in the fat-deficiency disease there is an inability to store fat, it seems evident that the more unsaturated fatty acids have some influence in enabling the organism to store fat in its depots and tissues.

ORIGIN OF THE STEROIDAL HORMONES

Significant among recent developments in chemistry has been the demonstration of the close similarities existing among the chemical structures of many physiologically important compounds. This resemblance extends in many instances into the realm of physiologic function. Particularly striking in this respect are the sex hormones and the hormonal substances of the adrenal cortex. All these compounds contain the steroid nucleus. Moreover, the similarity is further emphasized by the clinical syndrome of adrenal virulism, by the ability of certain of the sex hormones, e. g. progesterone, to restore the adrenalectomized animal, and by the recent actual isolation of progesterone as a constituent of adrenal cortical tissue. The problem of the origin of the steroidal hormones in the organism is therefore important. The processes by which the mammalian organism synthesizes these relatively complex molecules would, if understood, contribute greatly to understanding synthetic reactions in the body.

In the light of their chemical structure the steroidal hormones may arise from the degradation of cholesterol. The ubiquitous distribution of the latter steroid, containing the cyclopenteno-phenanthrene nucleus, and the presence of this nucleus in the sex hormones and in those of the adrenal cortex, makes this hypothesis of the origin of the steroidal hormones of particular interest. Indeed, from the point of view of theoretical organic chemistry it is possible to represent a mechanism for the conversion of cholesterol to a compound of sex hormone-like or adrenal cortical hormone-like activity. Moreover, actual experiment has demonstrated that certain of the steroidal hormones and related substances with physiologic activity may be prepared by the degradation of cholesterol and other sterols.[1] It has been claimed [2] that cholesterol may be converted by enzymatic actions into sex hormones.

Notwithstanding the evidence supporting this interesting hypothesis, certain objections to adopting this theory unequivocally become apparent. From a consideration of theoretical organic chemistry it is difficult to visualize the mechanism by which necessary oxygen atoms may be substituted into the steroid nucleus, a reaction required for supporting a biologic origin of the adrenal cortical substances from cholesterol. Moreover, the drastic conditions which must be employed in the laboratory to oxidize the side chain of cholesterol may be construed as an argument against the occurrence of this reaction in the organism.

In order to circumvent the objections to cholesterol as the "mother" substance of the steroidal hormones, Marker [3] has recently made some new suggestions regarding the origin and interrelationships of the steroidal hormones. During the past two years this investigator and his colleagues, working at the Pennsylvania State College, have published a long series of noteworthy papers dealing with investigations of the steroids in the urine of various species. Numerous reduction products of progesterone have been isolated. With the establishment of the structure of each of these compounds has come strong support for the suggestion that these products are all formed by biologic reduction of progesterone. Moreover, it is possible to hypothecate these reduction processes via reactions which are in good agreement with transformations known to occur in vitro. From urine there have also been isolated compounds the structures of which indicate that androstenedione, the corresponding parent male hormone, and also the cortical hormone, may undergo biologic reduction. From a consideration of the structural interrelationships among the many steroids isolated from urines and reported present in gland extracts, Marker postulates a hypothetical substance as the precursor of the steroidal hormones. The structure of this suggested precursor is closely related to the configurations of the known sex and adrenal cortical hormones; it is that of a substance with steroid nucleus and containing highly reactive groupings which are particularly susceptible to reduction reactions.

The logic of the arguments proposed by Marker in support of his hypothesis are, for the most part, sound. In some instances theoretical reasoning is employed which is criticized as being unreasonable. This is true in connection with certain reactions commonly considered as vigorous laboratory transformations and also in the suggestion of an involvement of enzymes in some

of the stages of steroid transformations. Nevertheless the arguments of Marker are thought provoking and serve to correlate the mass of data accumulated in his laboratory. Such ideas stimulate suggestions for future investigation of the important problem of the biogenesis of the steroidal hormones.

THE PLACE OF SULFANILAMIDE IN CHEMOTHERAPY

The recent review of Marshall [1] on the pharmacology of sulfanilamide correlates a vast amount of experimental work dealing extensively with the experimental results which form the basis for the intelligent use of sulfanilamide and related drugs in certain bacterial diseases. Interest in the search for drugs as bacterial chemotherapeutic agents was aroused thirty-five years ago by Ehrlich's results in chemotherapy. Marshall points out however that, despite the advances which have been made in the chemotherapy of protozoan infections since Ehrlich's time, the development of greatest practical importance in bacterial chemotherapy was the introduction, within the last few years, of drugs containing the sulfonamide group. Neoprontosil and sulfanilamide were at first thought to be specific against the beta-hemolytic streptococcus; however, subsequent investigation has indicated that these drugs or allied compounds may be effective against infection due to several different genera of bacteria. The efficacy of sulfanilamide in experimental mouse infections due to the meningococcus, gonococcus, Eberthella typhi and paratyphi B, Clostridium welchii, the Sonne strain of dysentery bacillus, and the staphylococcus seems to be well demonstrated. With regard to pneumococcic infection with types I, II and III in mice, the drug appears to possess some activity, although different investigators do not agree on the magnitude of the effect.

Sulfanilamide resembles urea and ethyl alcohol in its equal distribution in the organism, apparently diffusing readily into all tissues and fluids of the body. Although the acute toxicity of sulfanilamide under certain conditions has been studied on many varieties of animals, comparatively little information is as yet available with regard to the effect of repeated doses and chronic toxicity. While it is true that drugs may sometimes produce toxic effects in human beings which cannot be predicted from animal experiments, the value of such experiments in avoiding harmful effects in man is well known. Additional animal experiments will undoubtedly help to make the use of sulfanilamide as safe and effective as is compatible with its chemical constitution. With regard to the mechanism of the action of sulfanilamide, comparatively little is known. In this connection Marshall believes that the balance of evidence indicates that sulfanilamide affects the invading organism as a result of bacteriostatic or bactericidal action which, in many cases, is not sufficient to effect sterilization without the cooperation of the defensive reaction of the host. The relative roles assumed by these two factors probably vary, depending on different conditions of infection and concentration of the drug.

In the main, the results obtained with sulfanilamide and allied compounds in experimental infections in animals have been duplicated in the treatment of certain infectious diseases in man. Sulfanilamide has been tried in many types of disease; according to Marshall it is yet too early and the cases are too few to assess fully its value in most of the conditions investigated. The advent of sulfanilamide and related compounds has, nevertheless, altered in a favorable sense the prognosis of hemolytic streptococcus as well as other bacterial infections; furthermore, it has demonstrated the possibility of effective chemotherapy for bacterial diseases.

Current Comment

BACTERIAL EXAMINATION OF EATING UTENSILS

In a survey of the bacteriology of eating utensils, Carlisle and Hartinger [1] followed the technic employed by Cummings and Yongue, using brain-veal agar and plain agar in petri dishes as the culture mediums. The cultures from "clean," recently washed plates, cups, glasses and spoons which had been handled but not used for meals showed a total bacterial count for the entire surface of the plate, cup, glass or spoon ranging from 64 to 110, whereas cultures from used unwashed utensils showed a content ranging from 38,000 to 190,000. Dishwater remaining after washing dishes which had been handled and used by patients and personnel showed a bacterial count of 80 per cubic centimeter. This is below average expectation and means that few bacteria survive the exposure to hot soapy dish water. Dishes that were washed in hot soapy water at 172 F. and then rinsed in hot water at the same temperature were found to be sterile. Contamination found on unused utensils which had been handled but were still unused was due to ordinary air and hand contamination; pathogenic organisms were not found. Although tubercle bacilli were not found on the utensils in the combined ward mess for neuropsychiatric and tuberculous patients, it was recommended that the dishes after being washed in the usual manner at 172 F. be sterilized in a steam sterilizer for at least five minutes at a temperature of 212 F. The survey also demonstrates the necessity of avoiding air-borne and hand-borne contamination as much as possible—a problem which can be met by requiring hand washing prior to the handling of dishes. The cleansing of hands, the prevention of flying dust and the screening of mess hall windows, together with the bacterial examination of "clean" dishes, it is concluded, should constitute a regular routine for the purpose of maintaining a high degree of institutional sanitation.

ORGANIZATION SECTION

ABSTRACT OF HEARINGS ON THE WAGNER HEALTH BILL

(Continued from page 2442)

STATEMENT OF DR. BENSON

Dr. Cary:—The next one to speak will speak on the subject of the Care of the Indigent. I present Dr. Robert L. Benson of Portland, Ore., a member of the Oregon State Welfare Commission, and also a member of the Oregon State Board of Health.

Dr. Robert L. Benson, Portland, Ore., member of the Oregon State Public Health Commission and member of the Oregon State Board of Health:—For years I have been a member of the state relief and welfare agency of Oregon under three state administrations of three different political parties. Anything that I can say here is nonpartisan.

Senator Wagner:—May I interrupt you? I am a little curious, and I am sure the chairman won't mind. You said that you worked under three political parties. What is the third one?

Dr. Benson:—Independent. I believe I am familiar with the needs. In Oregon federal participation in general assistance was withdrawn in 1935. Since that time, Oregon has borne the burden of indigent care and has ministered generously to the relief of want. Road funds, liquor revenue and all possible sources of income have been diverted to meeting this demand. They have been difficult years, but in spite of this we feel that we have been successful. The Oregon state budget is still balanced and we are solvent.

The Pacific Coast section has recognized, like most parts of the country, that the millions of destitute people of the nation require material aid. Most urgent of these demands concern adequate shelter, necessary food, essential clothing and fuel. Secondary only to these is the need for medical care.

The following briefly describes Oregon's effective setup for handling the problems of the medically needy: The state relief agency always refers medical problems to its medical member for study and recommendations. He, in turn, has a full time medical adviser whose duty it is to visit all parts of the state to study their respective needs. We also employ a chief medical social worker under medical supervision to direct the activities of the various case workers as they are confronted with persons needing medical attention.

The Oregon State Medical Society is consulted on all important affairs relating to practice among the needy of the state. The society has a special standing committee which meets several times each month with the committee from the state relief agency to decide on policies to be adopted. The two, after collaboration, have a definite detailed plan for handling all questions relating to medical care of the indigent throughout the state.

The results have been gratifying. There has never been a situation that has not been ironed out. Diagnosis and treatment have been made available to the medically needy. Nursing care and hospitalization have been provided wherever needed. As far as possible, the time honored relationship of patient and doctor has been maintained, an exception being in the metropolitan Portland district, where the medical profession cooperates with the medical school clinic. Difficult cases are brought to the metropolitan center for study by a specialist in private practice, in a large number of cases. Autonomy in method of handling is left to the county unit and its medical adviser, subject to approval of the state relief agency.

The financial burden has been borne jointly by the state and the counties without aid from the federal government, usually on the basis of 60-40 or 50-50. Oregon is at present spending for medical care an average of about $1.07 per month for each person on relief, two thirds of which goes for hospitalization. This means an outlay of $4.28 a month per indigent family of four persons. Physicians have in general offered their services freely with the result that their fees outside of Multnomah County, the metropolitan area, have absorbed about 12 per cent of the total medical cost. The expense to the state amounts at present to about $65,000 a month, or a total for 1938 of $795,752.77. It is a small state in population, something over one million.

In the more thickly settled states of California and Washington the situation has been generally similar, but their accounting system is different and does not admit of ready comparison. Their needs are, however, identical with ours and their response to the need equally generous. The medical profession of the Pacific Coast states agrees fully with the profession of the whole country that the millions of people on public assistance throughout the United States must be furnished with adequate medical care. Our chief concern is that such aid shall be in a form that will uphold and improve the high standards of service previously achieved in medical practice.

The National Health Conference, held in Washington July 18, 19, 20, 1938, and which I attended, received five separate recommendations of the Interdepartmental Committee. Number III concerns Medical Care for the Medically Needy, and IV, A General Program of Medical Care with its implication of compulsory sickness insurance. In the Wagner Health Bill we find these two grouped under one heading: "Grants to States for Medical Care." Are we to infer that the proponent of this act undertakes to group indigent medical care and the care of the self-supporting brackets under one category? Again, must the state, to qualify for a grant, obligate itself to accept, besides the universally recognized need for indigent medical care, a program for medical care to income groups which may be incompatible with its local needs? We find such a plan highly objectionable and entirely unnecessary. Those who have had years of experience in relief agencies realize that indigent medical care requires one setup and that the self-supporting group must be handled in an entirely different way. It is essential that they be kept separate.

In conclusion, we are entirely in sympathy with the humanitarian principle of ministering in a generous measure to the medical needs of the indigent. Such care should be in the hands of the medical profession. Medical care of the lower self-sustaining brackets is a separate problem and should be met by a voluntary prepaid plan within the option of the state in which it is to operate. For the higher paid brackets of the population there is no need for any provision which will undermine self determination and independence. The advanced achievements and high standards of medical practice should be maintained at their present level and encouraged to further strides.

We shall be glad to further scientific medical progress in every possible way, but we cannot fail to oppose a proposal such as S. 1620, which will supplant these high standards by a system which is vague, visionary, inordinately extravagant and subversive of the best interests of an independent and self-reliant people.

Expenditures for medical care as proposed by the Wagner bill involving matched funds have been anticipated in Oregon by the County Judges' Association, which has expressed its inability to admit further large matching programs. The state legislature has expressed itself similarly. In conclusion, let me introduce a letter addressed to me this month by the governor of Oregon, Hon. Charles A. Sprague, as follows:

> In reply to your letter of May 1 with respect to the Wagner bill providing funds for public health administration, I wish to say that in my judgment of the state of Oregon is not in position to increase its contribution in the direction of social security.
>
> Last year about one third of its expenses for general assistance went for medical aid and hospital care. If these funds could be regarded as the state's contribution on a matching basis, we would receive additional sums from the federal government for use in the state.
>
> We are not unmindful of the need of proper care of the poor, but the tax burden which has been assumed for general social welfare purposes is as heavy as can well be sustained by our people.
>
> CHARLES A. SPRAGUE, Governor.

I close by stating that, while we have due regard for the need of adequate care for the needy, the feeling in Oregon in general is not in favor of greatly increased cost, and, as we are all aware, confining myself to the care of the indigent, there is proposed here for the first year $35,000,000 for medical care and unlimited amounts thereafter, and there is no provision as to

whether that will all go to the care of the indigent. Our concern is that these needy people, the really indigent, shall have whatever care is offered.

Senator Ellender:—Doctor, I am much interested in the Oregon plan that you have outlined. You say that the state contributed to the extent of about $100,000 per year?

Dr. Benson:—To what?

Senator Ellender:—Medical care.

Dr. Benson:—No, it is about $800,000.

Senator Ellender:—How is that money distributed as among the counties of your state? What is the yardstick?

Dr. Benson:—The county puts in a budget, and that budget is gone over and audited and passed on by the State Relief Agency. There is not a great deal of trouble in doing that.

Senator Ellender:—All of the counties of course do not get the same amount?

Dr. Benson:—No.

Senator Ellender:—It depends on their needs?

Dr. Benson:—It depends on their needs, yes, sir.

Senator Ellender:—What kind of service is furnished to these people?

Dr. Benson:—That is left to the local option, but in general we have a system under which the physicians have agreed locally to a fee schedule that will make possible care for all of these people under the budget at hand.

Senator Ellender:—Do you fix the fees?

Dr. Benson:—Yes, sir, we have a schedule of fees.

Senator Ellender:—In other words, those doctors take care of these indigents, the fee is fixed by the state?

Dr. Benson:—No, sir.

Senator Ellender:—How is it fixed?

Dr. Benson:—This fee has been fixed by the local medical society, the state medical society.

Senator Ellender:—Are the doctors paid out of this $800,000 that is raised by the state, and then the counties contribute?

Dr. Benson:—That is right.

Senator Ellender:—Does the same go for hospitalization?

Dr. Benson.—Yes, sir.

Senator Ellender:—Is that plan working well in Oregon?

Dr. Benson:—I think it is working very well. Of course it is not giving all of the aid that we would like to give, but I think we can say that the percentage who go without needed medical care is extremely low.

Senator Ellender:—But you could give better service and have better results if you had more money?

Dr. Benson:—Yes, sir.

Senator Ellender:—To what extent have the state agencies taken advantage of the Social Security money that is now being furnished to the state?

Dr. Benson:—We are using it.

Senator Ellender:—Is there any evidence of federal control in the state of Oregon by virtue of the use of this federal money?

Dr. Benson:—Yes, quite a bit.

Senator Ellender:—What is that?

Dr. Benson:—Quite a bit?

Senator Ellender:—All right. Will you tell us to what extent there is?

Dr. Benson:—I probably could not tell you to the entire extent which it has been done.

Senator Ellender:—No, but you have been in the state department for three administrations.

Dr. Benson:—I have not been in charge; I have been a member.

Senator Ellender:—You have been connected with it?

Dr. Benson:—Yes, sir.

Senator Ellender:—Tell us to what extent the federal government has shown control over the state agency by virtue of furnishing this money that your state does get under this law.

Dr. Benson:—The federal government is not participating except in certain programs.

Senator Ellender:—What programs?

Dr. Benson:—Old age.

Senator Ellender:—I am talking about the maternal and child care. I think under the bill they are now getting $3,800,000 for those services. Is the state participating to any extent in that fund?

Dr. Benson:—Yes.

Senator Ellender:—Will you tell the committee to what extent the federal government has tried to take advantage of that?

Dr. Benson:—Not very much.

Senator Ellender:—Can you qualify that? "Not very much" means some, to me. But to what extent has it taken advantage or has it taken control of it or had its hand in the pie, as it were?

Dr. Benson:—I might inform you that that is not under our agency in Oregon. That is under the state board of health.

Senator Ellender:—Would you know of your own personal knowledge if any influence has been used?

Dr. Benson:—I don't know of any at all, Senator.

Senator Murray:—Has there been any criticism by the medical profession that the federal government has interfered in that program?

Dr. Benson:—I imagine there has, Senator. If you think there is any federal or state agency that does not get criticism—you can be sure that there is criticism.

Senator Murray:—But you do not consider it justified?

Dr. Benson:—Well, I have no knowledge of any justified criticism of that control, no. Of course, it is not under our agency; we are not being concerned with it directly.

Senator Ellender:—Doctor, how would you look on a bill, let us say, drafted by this committee carrying out the same principles and the same medical aid that is being afforded now to the people of Oregon under the Oregon plan?

Dr. Benson:—I think that if it were confined to administering to the needy, to the indigent, I think that Oregon would yield to the same temptation that pretty nearly any state would of accepting a gift.

Senator Ellender:—How would you feel about it?

Dr. Benson:—I would be for accepting it.

Senator Ellender:—For accepting it?

Dr. Benson:—Yes.

Senator Ellender:—Your main reason, as I understand you emphasized in your answer to me, was with respect to the need for it; in other words, give it to those communities that want it and can show need for it?

Dr. Benson:—That is right. I want to qualify it further, however, that I would want to be absolutely certain, Senator, that the statement of that need came from Oregon if we are speaking of Oregon, or from any other state—

Senator Ellender (interposing):—Yes, but Doctor—

Dr. Benson (interposing):—Just a minute. I want to finish this answer because this is important to me.

Senator Ellender:—I do not want to cut you off.

Dr. Benson:—I do not believe in the promulgation of any big program that through propagation thrusts itself on states, and I fear that that is the trend in this bill. I think all the aid that the states need, and I know a state that is as honest in its administration as ours has been can be trusted with it, all the aid that would be acceptable to us is an aid that comes through our own application on the basis of a known need that is local, and we do not want any matching funds poured in our direction which would tempt our state and other states to just create a need. That is a temptation.

Senator Ellender:—Under this bill, as I understand it, you would not have any funds poured into Oregon unless it could show a need for it. The bill provides for certain yardsticks, and unless the states applying can measure up to those yardsticks, they are going to get nothing, and it is up to you to show a need for it under the specifications as contained in the bill. Now, if you or anybody else or any other witnesses can propose any other yardstick that would carry out what I conceive the bill has or what I think it has, I would like to have it made certain that no state or no community shall have any of these funds unless there is need for it. Certainly I would not want to advocate that the government collect taxes here and there and just simply pour forth just before the state asked for it; I don't want that.

Dr. Benson:—But here is the thing that you probably do not get here in the capital of the nation, but certainly we get it at home, and it is not only in our state but in all states, whenever it comes to the matching of funds, and we hear this stated time after time, not that we must have that but that we can get that. I am talking of, as I said before, a temptation which they will yield to.

Senator Ellender:—You have cited Oregon as a model state?

Dr. Benson:—One of the model states.

Senator Ellender:—Has Oregon obtained any money from the government that it was not entitled to under the laws since the federal government has gone into this way of trying to help the people of our nation?

Dr. Benson:—Now, I would have to answer that by saying that all things are relative. Needs are relative, and it is so easy for a state to show a need when it comes to a dollar for their 50 cents spent, and when their 50 cents spent suddenly grows into a dollar, there is certainly a temptation to feel a need that they did not need before. I know that is true in Oregon and in other states; it is human nature.

Senator Ellender:—Notwithstanding the fine reputation that you have given to Oregon, still you think that if the opportunity is afforded that they would probably ask for it?

Dr. Benson:—Yes, I do; we are human.

Senator Ellender:—That is your view?

Dr. Benson:—Yes, sir.

Senator Ellender:—Well, there is a lot of weight to that view.

Senator Wagner:—You read a letter from your distinguished governor, and I want to read another letter that came out of the West. I will just read portions of it

Our experience in dealing with problems of dependency during these past years has impressed upon the health and welfare administrators of this state the significant part that ill health and inadequate health facilities play in the lives of people who are recipients of public assistance. Consequently, in the development of our Social Security Program, we have seen a close working relationship between these two branches of public service. Out of this experience has come the realization that an expansion of public health facilities will play a large part in our future attempts to lessen the economic and social dependency of our citizens.

Further on in this same letter it is stated:

We have read the material that has been gathered over the past several years by the Interdepartmental Committee on Health and Welfare, and we realize that these exhaustive surveys undoubtedly have brought to the attention of the committee the facts underlying the whole problem and the plans outlined to meet the problem. However, if there is any further information that you believe we might supply, please feel free to call upon us. We shall continue to watch with interest the progress of this constructive legislation.

Sincerely yours,
CLARENCE D. MARTIN,
Governor of the State of Washington.

He takes apparently a different view, doesn't he?

Dr. Benson:—No, I do not think so, Senator. That was largely public health, you see. I am, like most members of the medical profession, in favor of enlargement of public health activities. For instance, just to make my point clear, if we were to spend a sum of money to go down in Florida, or any other state—I used to live in Florida and I think of the way the mosquitoes used to bite there and I had malaria there, and I had a fever too both from mosquitoes—if those swamps are to be drained and we can rid them of those diseases, and also of the yellow fever that Florida had that swept away a large percentage of their people, I am for that too, more and more development in a reasonable way of public health.

Senator Wagner:—In anything that I say I do not want you to understand that I question your desire to improve the public health. We are all for that, but we are trying to find a method.

Dr. Benson:—That is what Governor Martin is speaking of there.

Senator Wagner:—He is speaking of the whole program—I did not read the whole letter, but I will read the portions that I did not read previously:

As a recognition of this need, the 1939 state legislature made provisions for making moneys available in the event that the federal government inaugurates a national health program through which matching funds will be made available to the respective states. This is an indication that the state of Washington recognizes the principles of such a program and is ready to accept them should congressional action put them into effect. It is my understanding that a national health program, such as the one outlined in the bill which you have introduced, would fit in with existing health and welfare programs, and would, therefore, augment the services now available. It would give federal financial assistance to many of the phases of the program which the states and counties are operating on a small scale now. Where deficiencies in the services are already recognized, such assistance would prove of great value to the respective states as they carry out their programs of social security and public health. It is my further understanding that the legislation which Congress has before it aims to assist states along the lines of the health and welfare programs which the states themselves have initiated.

In talking about health, one of the doctors this morning I think minimized a little bit the extent of need of more adequate health service. Here is a statement from the head of the Welfare Department of New York:

A recent study made by the Department of Welfare of New York City indicates that, in New York State, sickness of the breadwinner alone is responsible for approximately 15 per cent of the cases on home relief—and this is merely one type of public aid. In other words, in any one month in this state, over 136,000 men, women and children and more than 47,000 cases are dependent upon home relief because the wage earners have lost their jobs through illness. The approximate cost of this burden is over $22,000,000 annually. And, remember, we are excluding institutional care, those persons served by the hospital and health departments and all other forms of public aid.

You see what a great economy we could in the long run provide by making our citizens healthful. I am sure you agree with every word of that.

Dr. Benson:—Senator, in comment on that, that whole matter relating to prepaid care of industrial groups is an interesting topic and we could drag on here for days. If I could make my position clear, I am sure that you won't find it so unreasonable—

Senator Wagner (interposing):—I do not think you are unreasonable.

Dr. Benson (continuing):—As regards my ideas on indigent care, but I believe that the state and the counties, the political subdivisions, should furnish adequate medical care for the indigent, and I go further and I believe that, if they are unable to furnish all that, they should go to the federal government and ask for a grant as a gift or on a matching basis, a grant in aid. My whole point is that I feel that the matter should be simplified. We should be kept within bounds so that the federal government is on a balanced budget the way my state is. Mine is a poor state, but we are on a balanced budget, and I believe the federal government ought to be.

Senator Murray:—We will stand in recess then until tomorrow morning at 10 o'clock.

(Whereupon, at 4:20 p. m., a recess was taken until Friday, May 26, 1939, at 10 o'clock a. m.)

Friday, May 26—Morning

The subcommittee of the Committee on Education and Labor of the United States Senate met at 10 a. m. in the Senate Office Building, Senator James E. Murray (chairman) presiding. Present were Senators Murray, Ellender, Thomas and Davis. Also present was Senator Robert F. Wagner.

Senator Murray introduced into the record some statements of witnesses who were not going to be present.

One from Mr. H. B. Anderson, secretary of the Citizens' Medical Reference Bureau, Inc., with headquarters at 1860 Broadway, New York.

Also a resolution passed at the National Convention of the National Lawyers Guild, held at Chicago Feb. 12, 1939, pertaining to a National Health Program.

Also a statement of the United Rubber Workers of America, to the Senate Committee on Education and Labor, on the National Health Program.

Also a statement on the National Health Bill by the Amalgamated Clothing Workers of America.

Also a statement made by the United Office and Professional Workers of America.

Also incorporated in the record was a statement of Dr. Walter E. Vest of Huntington, W. Va., president of the Public Health Council of West Virginia, Huntington, editor of the *West Virginia Medical Journal* and past president of the West Virginia State Medical Association.

STATEMENT OF DR. WALTER E. VEST ON INSURANCE AGAINST UNEMPLOYMENT DUE TO SICKNESS

Dr. Walter E. Vest:—The disability compensation program dealt with in title XIV of the Wagner Health Bill is collaterally allied to rather than an integral part of a medical care program. Essential medical care will materially reduce the cost of disability insurance, and appropriate hospitalization and scientific rehabilitation, however provided, are necessary to keep the actual expenditure incident to such a program within reasonable bounds.

Compensation for loss of wages during illness may, when a part of a mutual voluntary indemnity insurance plan, have a favorable influence on the duration of disability and early return to employment. Self interest and self respect tend to prevent abuse of mutual indemnity plans.

Where the workman's financial responsibility is small in proportion to the benefit expected during disability, there is a tendency to assume and take advantage of a state of invalidity. In other words, the workman has a financial interest in assuming and continuing a state of apparent invalidism.

Properly safeguarded, payments for wage loss due to sickness, administered in like manner as payments compensating for unemployment due to other causes, would relieve much of the economic burden of illness in the low income segment of the population.

The American Medical Association endorses the principle of insurance against loss of wages during sickness. It is indispensable, however, that the physician's function in caring for the sick workman should be completely separated from medical certification of compensable disability. This should be the function of a qualified medical employee of the disbursing agency.

The Wagner Health Bill, however, is not satisfactory for the following reasons: (1) It requires the furnishing of medical services in addition to cash indemnity, (2) it furnishes a stepping

stone toward universal compulsory sickness insurance and (3) it provides for federal control of what should be essentially a state function.

Senator Murray:—Is Homer Folks here?

Mr. Folks:—Yes.

Senator Murray:—Will you come forward, please? Mr. Folks, I understand that you are anxious to get away and desire to make a statement at this time?

Mr. Folks:—That is right, sir, both.

Mr. Homer Folks, secretary of the State Charity Aid Association, New York, then presented a statement favoring the Wagner Health Bill.

ABSTRACT OF STATEMENT BY HOMER FOLKS

Mr. Folks:—In the United States in 1938, 69,324 persons died in the fruitful years of life, in the early middle aged period, when they are carrying the major responsibilities of life to their families and their communities, from a cause which we do understand, from a cause which we can control, which we are very slowly approaching a control of but which, if we only applied more fully what we now know, could be eliminated as any substantial cause of death in a very much shorter time than it otherwise will be. It is a national problem because these deaths are distributed over the entire country.

A second reason for federal participation is that no one state can do it alone.

The third reason is that while the cities and counties and the states have heretofore done quite a bit. They cannot now provide the sums required for hospital care.

Now the National Tuberculosis Association has just three points in its plan, which I say in substance is in the Wagner bill. The first of those is that we plan over a period of years to bring the number of tuberculosis hospital beds up to a minimum of two per annual death in each state in the Union. We suggest in our plan that the federal authorities aid for a period of six years in the maintenance of the additional hospital beds, not the existing ones. Third, that the federal government assist the states in finding the cases of tuberculosis which most need to be hospitalized. There are new methods of doing that, developed within the last few years, the significance of which is only relatively as yet understood; namely—I am speaking now for the National Tuberculosis Association, not of my personal knowledge professionally because I am not a doctor, but I know their views—that tuberculosis, early tuberculosis, can only be discovered definitely by an x-ray examination of the chest, and in no other way; that no practitioner without an x-ray machine can discover early tuberculosis.

Senator Murray:—Is that proposition recognized by the medical profession generally?

Mr. Folks:—I don't know, I guess so, I hope so, I think so. It is recognized by the National Association for Tuberculosis where the experts are—at least. They certainly must know it. If you are really going to find the people who are in a stage when they can be cured readily, you have got to go at it with the x-ray examination of the chest. And so we propose here that the federal government assist in that particular matter up to 50 per cent.

As an individual, I did my home work on the Wagner bill last night, a second time. I read it through from the first word to the last one and gave the whole evening to understanding it and seeing it. I have been a little critical of it at times, as it seemed to be pretty complicated and pretty hard to understand. I finished up last evening with an entirely different feeling about the bill as a piece of workmanship. To my mind it is a splendidly written piece of legislation. It wasn't just written, it grew, it is coherent, it is consistent, it is in harmony all the way through, and to my mind it is an excellent piece of bill drafting, and I hope it will get your most serious and favorable attention.

STATEMENT BY DR. CHARLES GORDON HEYD

Dr. Charles Gordon Heyd, New York, professor of surgery, New York Post-Graduate Medical School, Columbia University, was presented.

Dr. Heyd:—Mr. Chairman, I should like to draw to your attention a paragraph from the proposed National Health Act of 1939, page 5, paragraph 7, line 7:

> Provide for cooperation and, when necessary, for working agreements between the state health agency and any public agency or agencies administering services related to the services furnished under the state plan, including public agencies concerned with welfare, assistance, social insurance, education or medical care.

This paragraph appears twice in title V, once in title VI, once in title XII and once in title XIII.

This bill, therefore, expressly provides for working agreements, "including social insurance." Furthermore, two individuals and one executive control, administer this bill. First, the Chief of the Children's Bureau; second, the Surgeon General of the Public Health Service, and third, the Social Security Board.

These three individuals, with the consent or approval of the Secretary of Labor and the Secretary of the Treasury, "shall allot to the states the sums appropriated in accordance with rules and regulations which they shall make and prescribe."

It has been said that the power to tax is the power to destroy, and the power to give and withhold money is the power to coerce and control. There is, inherent in this bill, the power to dominate the entire field of medicine and to induce states to submit plans to certain three individuals in Washington, or bureaucrats, and "Failure to comply substantially with any requirement . . . further payments will not be made to the state" (page 22, sec. 605, line 12).

Senator Murray:—Wouldn't it be necessary, doctor, to have any law that way, that they would set up a formula or a basis for the granting of the assistance and if they didn't comply, then they wouldn't be entitled to receive the assistance?

Dr. Heyd:—That is true; the Comptroller General has to see that the funds are distributed within the law.

Senator Murray:—That is the only way anyhow—

Dr. Heyd (interposing):—But the prescribing of the rules, Mr. Chairman, is by these three individuals.

Senator Thomas:—Whom would you have them by?

Dr. Heyd:—Whom would I have them by? May I, Mr. Chairman, finish my remarks, and then I shall be perfectly willing to answer any questions.

Senator Thomas:—Excuse me, Doctor, but I have to run, and that is why I asked the question here.

Dr. Heyd:—Senator, I am trying to present an argument and if I stop I really believe that it will invalidate the continuity of the argument.

This bill would create a vast, complicated system of sickness insurance with a centralized control by the federal government of every phase of medical service. It would control the education of doctors, hospitals, the distribution of medical services, pharmaceutical houses, instrument makers, and all of the allied industries that go to the field of medicine.

It would provide a vast bureaucracy for the distribution of medical services and in essence would be a form of national sickness taxation. The government would have to collect the money, approve of it, distribute it, employ trained laymen and professional personnel for its distribution. It has all the defects that are inherent in the compulsory health system in any of the totalitarian states.

Furthermore, the bill will not provide good medical service. It deals with quantity rather than quality, and it provides a means for distributing minimum medical service.

There is not in the bill any provision for periodic health examinations, immunization, for any discoveries in the field of medicine. It freezes medical science and makes it static instead of allowing the onward procession with scientific progress.

Furthermore, the bill will increase illness because it gives an alleged "free medical service." Paradoxical as that may seem, the history of sickness insurance is an increase in illness. In Germany, in 1888, thirty-three individuals out of 100 availed themselves of sickness insurance. In 1925, 52 per cent, or more than half of the people insured.

Again, in the number of days of sickness, there was a gain. The number of days of sickness per hundred insured increased in the same period of time from 547 days to 1,250 days.

This bill, with its implicit instructions for sickness insurance, social insurance, will sterilize medical discovery. There isn't an American, be he layman or doctor, that is not proud of the contributions of American medicine during the last twenty-five years—insulin, vitamin therapy, liver therapy for anemia, high voltage roentgen therapy, increase in the knowledge and advancement in the treatment of cancers are all due to the free enterprise of science and the medical world in this country because it is not shackled by government control.

The bill will prolong illness. In the United States a workman will lose six or seven days a year. In England, under the panel system, nine or ten; and in Germany, fourteen. When an individual is given alleged "free medical service," there is no particular urge for him to get well quickly.

Senator Wagner:—Would you mind repeating that again?

Dr. Heyd:—When an individual is given alleged "free medical service," there is no particular urge for him to get well quickly.

Senator Murray:—What do you mean by that, Doctor?

Dr. Heyd:—Let me make a note of that and I will come back to that when I am through.

Senator Murray:—All right.

Dr. Heyd:—Now the second phase of my argument.

The phrase "including the training of personnel," page 8, sec. 5, line 22, occurs six times in titles V, VI and XIII and actually compels the various states to pass enabling acts. There are at least seven of the states of this country in which enabling acts have been passed or have been introduced. I need only refer to the Goldstein bill in New York, which was introduced in the assembly of New York State, which provides for the complete regimentation of the medical profession. I beg to submit here a copy of the Goldstein bill.

Senator Murray:—That may be filed with the committee.

The document referred to was filed with the committee.

Dr. Heyd:—I would like to quote one portion from that proposed legislation:

> In the event an insufficient number of persons elect to become members of the staff pursuant to this section within one year after this section as hereby amended takes effect, any additional number of staff members shall be procured by aiding students and prospective students to obtain the necessary training, experience and qualifications at professional schools and colleges with a financial subsidy of not to exceed one thousand dollars per annum to each such student who will agree, upon graduation from such school or college, to elect to become a member of the staff subject to the terms and provisions of this chapter and the rules and regulations of the department for a period of at least three years.

In 1933, while in Moscow, I heard those identical words of that paragraph from the Assistant Commissar of Health.

Now the training of personnel by government subsidy will entirely change the basis of our education. It will lower the quality, remove the basic qualifications and make entrance into a medical school dependent on favor, recommendation.

Furthermore, this bill jeopardizes the voluntary hospitals. This American hospital system is a peculiar product of our civilization and culture—the integration of voluntary effort into government effort. It works well, and yet there is not one word in this projected bill that will maintain this marvelous structure of the voluntary hospitals.

Furthermore, the bill does not solve medical indigence. It does not supply an adequate, efficient medical or dental service. A huge bureaucracy is created. Fifty per cent of the personnel will be nonprofessional people, and the amount of money that is spent for medical care will be that sum of money less the cost of the administration of this huge lay personnel.

Psychologically and fundamentally, it destroys character because the giving of something for nothing undermines character, and the idea that the government can pay for everything brings about a slow deterioration of the race.

Furthermore, this bill will dominate all citizens because a complete control of the medical service, such as is envisaged in this bill, will mean that every citizen is under the control, in one way or another, of the influence of this bureaucratic medical system.

Senator Wagner, I think this will explain in a measure the little doubt that I didn't make myself clear.

Under this bill cash benefits for wage loss, while sick, impairs the physician's usefulness and in turn blackmails the doctor. The effect of making the doctor certify to cash benefits for sickness places the physician under the economic necessity of certifying illness for fear of losing his patients, and if an individual is treated in a hospital, receiving compensation while he is sick, and he is maintained in that hospital at government expense, he has very little incentive to get well.

Understand me, I am for paying the workman when he is sick, his wages, but he should be paid from the organizations that deal with unemployment. It is not part of the distribution of medical services.

This bill is financially wasteful and extravagant. The form of poor relief or medical dole is incorporated therein.

Since taxes are spread generally, they must be paid in the long run by the great mass of the people.

Now you have distributed funds through the Public Health Bureau and the Child Welfare Bureau without any difficulty and you have given to the state of Nevada, under the Children's Bureau, for 1938, $1,614. The Public Health Bureau in the same time gave, in the state of Nevada, $411. The total of those two amounts is $2,025.

Now the basic cost of distributing all of the public health services in any state, be it a low expense state or a high expense state, is $1.31, and that is the figure that the populace in the rich state of New York spends. Yet the state of Nevada received $2.02.

So I bring that as an example of financial waste and extravagance.

Senator Murray:—Doctor, in the state of Nevada you have tremendously wide stretches of territory; you couldn't expect a state like that to maintain the low cost of service that you would in a big state like New York or in any part of the state of New York, isn't that true?

Dr. Heyd:—I will grant you, Mr. Chairman, that that is an offset.

Mr. Chairman, there is no magic in government spending. Government does not create money or values. This National Health Bill will, it is true, spread the cost of medical service. It must be paid for in taxes, there is no such thing as free medicine, but it will buy less medical service than the same amount of money spent as under the present setup.

This bill with its centralized control is an implement of the totalitarian state.

Senator Wagner:—What is that?

Dr. Heyd:—This projected bill, that bears your name, is an implement of the totalitarian state, with its centralized federalized control.

Senator Murray:—You see out of this a totalitarian state coming?

Dr. Heyd:—No, no, I said it is one of the implements.

Senator Wagner:—I see.

Dr. Heyd:—Gentlemen, it is easier for any one here, or you, to walk out of this building and get medical service, than it is to get food or shelter or clothing, and aside from certain areas in the United States, which organized medicine freely admits need care and want care and are perfectly willing that Mr. Wagner shall give them care under certain institutions and organizations, but it is easier to get medical care in the five or six thousand towns, of over ten or fifteen thousand population, a stranger, than it is to go out and get shelter or food or clothing.

Senator Murray:—Doctor, your statement is a severe indictment of the bill, but I am sure that we all welcome it. It will stimulate our study and close analysis of the bill. We want the medical profession to come here and attack the bill with all the force they possess, because if there is anything wrong in it I am sure that Senator Wagner and every member of this committee wants to correct it. I think that the medical profession is best fitted to come here and do that job of analyzing this measure, and I want to thank you for your very strong statement. Of course we may not thoroughly agree with you on everything, but it is going to stimulate our very close study of the bill.

Dr. Heyd:—Thank you so much for your courteous treatment.

Senator Ellender:—Doctor, if I am to understand your argument, you don't believe that the federal government should spend any money for such purposes?

Dr. Heyd:—I didn't say that, Senator.

Senator Ellender:—Well—under what circumstances, then, would you permit the federal government to aid the states?

Dr. Heyd:—Whenever the need is demonstrated.

Senator Ellender:—All right. That statement has been made by every physician who has so far appeared for the American Medical Association. What I am very anxious to have written into the records is your views as to how that can be done. Now you needn't have in mind that we want you to dictate in the record a bill to that effect, simply give us the ideas and we are going to get the lawyers who draft our bills to do the work.

Dr. Heyd:—I am happy to comply with that, and welcome the opportunity. My first point in my argument is to present what I believe are the dangers here.

Senator Ellender:—Let's forget that bill and you say you are in favor of having the federal government aid the states?

Dr. Heyd:—Yes, sir.

Senator Ellender:—To help the sick?

Dr. Heyd:—Yes, have the federal government create a Department of Health to coordinate all health activities.

Senator Ellender:—Would you say that the present health department is insufficient?

Dr. Heyd:—I am not here and I have no competence to criticize the present health department.

Senator Ellender:—I am not talking about the personnel, forget the personnel; I am talking about the law establishing it.

Dr. Heyd:—Senator, you asked me for my views as to how I would get federal money to those deserving areas.

Senator Ellender:—Yes, sir, and you said the creation of a federal department—

Dr. Heyd (interposing):—A federal Department of Health.

Senator Ellender:—You have that now under the federal government. Would you improve on that or would you suggest any changes, or how would you do it?

Dr. Heyd:—The creation of a federal Department of Health; two, a Secretary of Health; three, the coordination of all health activities in that department; four, the creation of a sufficient sum of money under proper legislative and Congressional controls in that department; and five, the allocation of funds from that amount on due presentation and demonstration of the need, wherever that need may be.

Senator Ellender:—Now let's go to your first suggestion. Would you improve the law that is now on the statute books with reference to the creation of a health department?

Dr. Heyd:—I am not competent, Senator, to offer any criticism as to the law. I have never been trained in it.

Senator Ellender:—Now why do you mention a Secretary?

Dr. Heyd:—Because if medicine is one of the three great industries of this country, and the whole ideology of the Wagner bill is to save sick people, I think it needs a full-time man, trained to do nothing else but that.

Senator Ellender:—You mean to take care of—

Dr. Heyd (interposing):—All the health activities of the federal government.

Senator Ellender:—One Secretary?

Dr. Heyd:—Yes.

Senator Ellender:—Would you make that a cabinet officer or what; how would you handle that?

Dr. Heyd:—I think if I were handling one of the two or three biggest industries in the country, as big as most of the other departments, that that should be a cabinet officer.

Senator Ellender:—Now you know the goverment must appropriate each year funds before they can be distributed among the states. Now what would you start that fund at?

Dr. Heyd:—Senator, I know less about that than you do. I am not competent to tell you how much money would be required. I know that this bill projects nearly 900 million in three years.

Senator Ellender:—How much?

Dr. Heyd:—Nine hundred million, doesn't it, within the ten years that it is supposed to run—well, it doesn't matter, the figures are there.

Senator Ellender:—I don't think your figures are correct.

Dr. Heyd:—They may not be.

Senator Ellender:—How would you define "need"? Who would determine that?

Dr. Heyd:—I would have a man like Homer Folks to tell me what the needs were.

Senator Ellender:—How would you organize that, who would have the power to organize and appoint Homer Folks?

Dr. Heyd:—The federal government.

Senator Ellender:—What rights would the states have in supervising this work, if any?

Dr. Heyd:—I am not prepared to answer that, I am not a constitutional lawyer.

Senator Ellender:—I am asking you, under your plan would you have the state cooperate with the federal government or vice versa, or who would have the last say, let's say?

Dr. Heyd:—The last say, as it is now, with the federal government.

Senator Ellender:—In other words, any plans that would be worked out, and in which the federal government would furnish money, you would expect the federal government to maintain authority?

Dr. Heyd:—Yes.

Senator Ellender:—And what authority would you vest in the states?

Dr. Heyd:—That I am not prepared to answer; I can't frame a bill on my feet; I am only anxious to prevent this train coming into a washout with a red signal.

Senator Ellender:—Of course you know this, that I, and nobody else on this committee, would vote to surrender the rights that belong to the states to the federal government.

Dr. Heyd:—We are both agreed on that.

Senator Ellender:—But under your plan that is what would happen; in other words, you would direct it all from Washington, as you say, and the entire matter would be left to the Secretary and the Public Health, and the states would have nothing to do with it?

Dr. Heyd:—Oh no, after the need had been passed on and the money had been given to the states, a state, local organization, state or county or municipality, would distribute that money for the purposes that were written into that grant.

Senator Ellender:—Well, the need, then, would be determined by the federal government through a person appointed by the federal government, and, after that need was made certain, then the federal government would turn over to some state health service, or whatever might be established. Now to what extent would you permit the federal government to oversee, as it were, these funds after they got into the hands of the state department of health?

Dr. Heyd:—That is already, I think, in the law, that the Comptroller General must see that the funds expended are within the terms of the enactment, or whatever it is.

Senator Ellender:—And you wouldn't consider that federal control, that is, the taking away of states' rights, would you?

Dr. Heyd:—I think that we differ in our point of view. The federal government, if it puts up money, obviously must have control over the money. I am talking about the federal control of medical service.

Senator Ellender:—Well, what I was trying to get from you was some plan that you would make, don't you see, and which would not incorporate all of these various phases of this bill that you are not in agreement with. Now just what authority would you give the federal government after the funds reached the state?

Dr. Heyd:—I am not prepared to answer that, that requires thought and consideration. I am not competent to do that.

Senator Murray:—Doctor, could you study out this matter and submit a plan that you think might be feasible?

Dr. Heyd:—I am quite sure the American Medical Association, with its people, could work out that detail if there was a failure to accomplish it in Washington.

Senator Murray:—In other words, you feel that a National Health Program would be proper, but you—

Dr. Heyd (interposing):—I did not say that, Mr. Chairman. I did not say that. Senator Ellender asked me what I would suggest to meet conditions of local need or medical need and I submitted what I thought was a competent and effective plan, the Department of Health, the Secretary, all medical activities in that department—

Senator Ellender (interposing):—Am I to understand that although you suggest that plan you would be against it?

Dr. Heyd:—Against the Wagner bill 100 per cent.

Senator Ellender:—Now would you leave this question of the determining of need solely in the hands of the party appointed by the government or would you have this party cooperate with the state agency who is to spend the money?

Dr. Heyd:—Either way, it could be worked out amicably. When minds are for the same objective, they can usually meet if the fundamental principle is sound.

Senator Ellender:—Now, Doctor, you have stated that a person who receives treatment is not as likely to get well as one who must pay for it; am I right in that?

Dr. Heyd:—I will accept your version of it, yes.

Senator Ellender:—You don't believe in Christian science?

Dr. Heyd:—Do I believe in Christian science?

Senator Ellender:—Yes.

Dr. Heyd:—You mean as therapy or medical treatment?

Senator Ellender:—I don't know, but I would judge from the question that I have just asked and to which you have agreed that is on the borderline of Christian science, as I, as a layman, understand it, that it is a working on the mind, isn't it? The fact that I go to a hospital and I mustn't pay, I will just stay in bed and accept the hospitalization?

Dr. Heyd:—I think that is true in about ninety-five out of 100 cases.

Senator Ellender:—Do you like to stay in the hospital?

Dr. Heyd:—Yes, sure.

Senator Murray:—Doctor, I would like to go to a hospital and stay there a week now and get a good rest. (Laughter.)

Senator Ellender:—Would you expand on that for us?

Dr. Heyd:—Yes, and I will give you a direct answer to it.

Senator Ellender:—I don't mean these chronic cases, I mean generally speaking?

Dr. Heyd:—You mean, like you might be sick after this session?

Senator Ellender:—Yes, but I have, seriously, been sick just a few times and I was glad to get out of the hospital, not because it cost money but to get out of that environment.

Dr. Heyd:—Let me explain that to you. Here is an individual. I want time to make two examples. Here is an individual who doesn't like his job particularly and he develops a nice big boil on the back of his neck, and he goes to a hospital and he is fed well and he has a lot of pretty girls wait on him and he has dressings. Do you suppose that fellow is in a hurry to get out and go back to work?

Senator Ellender:—I don't think a man who has a boil would be admitted to any of these hospitals; just open it and put him out.

Dr. Heyd:—Did you ever have one?

Senator Ellender:—Yes.

Dr. Heyd:—With a temperature of 104 and the possibility of meningitis and dying?

Senator Ellender:—That is a different proposition; if those conditions exist I would then say he ought to stay in. And another thing, Doctor, it strikes me that any plan that would be worked out by the federal government through the states would leave it to the doctors to determine that, as to whether or not he should remain there, as is done now in charitable institutions that I know of in my own state. They usually give them a card and say "You are well" or "You have got to be transferred" or something of that kind. Isn't that usually true?

Dr. Heyd:—Right! Example No. 2. The Associated Hospitals in New York City have over one million subscribers. You are familiar with that. That is the three cents a day plan. Under their plan, by paying $10 a year, any individual, a policyholder, can, on the advice of a doctor, go to a hospital. Under that plan all the hospital charges are paid up to thirty days. In 1938 the admission of people to hospitals with colds, with trivial cuts, was so great as to practically make severe inroads into the reserves of that organization, showing you that when people do not pay for their per diem maintenance in hospitals they tend to prolongation.

Example 3. In the Veterans' Hospitals it takes twenty-nine days to take out tonsils and discharge the patient. In civilian hospitals it takes three to four days.

Senator Ellender:—And you attribute that to the fact that in one instance they must pay and in the other they must not?

Dr. Heyd:—The psychology of getting something for nothing.

Senator Ellender:—I know. But is not the medical profession, that is, the person who does that, to blame largely, not the patient?

Dr. Heyd:—They are particeps criminis, I believe.

Senator Ellender:—Don't you think they are 99 per cent criminis?

Dr. Heyd:—Oh no.

Senator Ellender:—I don't know, but it strikes me that the—

Dr. Heyd (interposing):—Don't forget the doctors in the Veterans' Hospitals are government employees.

Senator Ellender:—Civil service—the merit system. (Laughter.)

Senator Ellender:—On page 5 of the bill you cited section 7?

Dr. Heyd:—Yes, sir.

Senator Ellender:—And I understand your conclusion, that is, what you derive from that section, is that it may lead to socialized medicine; am I right?

Dr. Heyd:—It is inevitable in the terms.

Senator Ellender:—Personally I am not in favor of that, Would you suggest any language to negative that?

Dr. Heyd:—I cannot suggest language on my feet to cover such an important matter.

Senator Ellender:—Of course these hearings are not going to close today, and we expect to hold hearings later, but would you have some one to suggest?

Dr. Heyd:—No sir, you can't patch this house up.

Senator Ellender:—Wait a minute, Doctor, let's not take the entire bill. I am talking about that portion of it dealing with socialized or social medicine, and you cited this paragraph on page 5 and several others that would lead you to believe that that is inevitable if that language, as I understand it, is retained. Now what I would like to have is a suggestion from you or any member of the Association, in fact anybody against the bill, who thinks that this would lead to socialized medicine, that language, I would like to have it negatived.

Dr. Heyd:—Senator, it is my considered opinion that you cannot amend this bill and make it workable.

Senator Ellender:—That is all.

Senator Wagner:—Doctor, you just said people getting something for nothing, that that is the psychology which keeps a man in a hospital longer than he should?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Do I understand you to mean by that that people who are poor and helpless and sick and want to get well ought not to receive any care because they can't afford to pay for it?

Dr. Heyd:—No sir, they should receive all the care they need.

Senator Wagner:—What do you mean, then, by this thing you just said a moment ago, that getting something for nothing is just prolonging illness rather than curing it?

Dr. Heyd:—There comes a time, Senator, when a person, after an illness or an operation, a certain given number of days, when he is considered well enough to go home.

Senator Wagner:—I am not talking about that, I have heard that, I don't agree with you at all, but that isn't what I am talking about. I am talking about the person that hasn't got the money to pay for an operation and he is sick and he is helpless, what about that person?

Dr. Heyd:—Senator, won't you be fair and let me finish my argument on that?

Senator Wagner:—You started it, you said after an operation—I am talking about something before an operation, I am talking about the person that hasn't the money with which to pay for an operation, and yet he needs it and he is very ill and he is poor, he hasn't the money, he is in that lower income group. What about that person?

Dr. Heyd:—He should receive medical attention without any question.

Senator Wagner.—Aren't you afraid of ruining that person by giving him medical attention because he is getting it free?

Dr. Heyd:—On the contrary, we are making him well.

Senator Wagner:—You said a moment ago that getting something for nothing makes persons ill rather than well.

Dr. Heyd:—No, it tends to prolong illness, they are totally different, Senator.

Senator Wagner:—Tends to prolong illness?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Well, we don't want to prolong illness, and how are we going to stop it?

Dr. Heyd:—I don't think you will stop it under your bill.

Senator Wagner:—How would you stop it?

Dr. Heyd:—I would carry on the present medical system that has been so successful.

Senator Wagner:—Has it been?

Dr. Heyd:—Has it been successful?

Senator Wagner:—Yes.

Dr. Heyd:—I am going to give you the answer, that it has been.

Senator Wagner:—Aren't you relating what you are saying as the result of your experience?

Dr. Heyd:—Yes, sir.

Senator Wagner:—That helping these people that are getting it for nothing prolongs their illness?

Dr. Heyd:—Yes.

Senator Wagner:—Don't we want to cure them?

Dr. Heyd:—Certainly.

Senator Wagner:—How are we going to do that?

Dr. Heyd:—Under the scheme that I outlined to the Senator, centralized Department of Health, and—

Senator Wagner (interposing):—Is that the way you are going to do it?

Dr. Heyd:—Carry on the present medical setup that has been so effective and aid areas that need help by federal funds.

Senator Wagner:—Aren't you going to set up—I understood you to say that you wanted to substitute another setup?

Dr. Heyd:—Not to destroy the present medical distribution, no, sir.

Senator Wagner:—Well, does this bill destroy the present method of distribution?

Dr. Heyd:—In my opinion it does.

Senator Wagner:—Well, what is it that does?

Dr. Heyd:—Well, if this bill were enacted you would have forty-eight commissioners of health coming to Washington, to interview three individuals and making requests for allotments, and they would or would not get those allotments, and when you have the power to give or withhold money you can coerce or control that medical service.

Senator Wagner:—Now let's get right down on that point. What did you suggest in place of that; didn't you suggest a moment ago a Department of Health?

Dr. Heyd:—Yes.

Senator Wagner:—To which the forty-eight states would come?

Dr. Heyd:—No, sir.

Senator Wagner:—Who would come?

Dr. Heyd:—Any subdivision of the states that had a local need could come and petition that department and have the merits of their request passed on.

Senator Wagner:—Well, what is the difference between the state coming and any subdivision of the state coming?

Dr. Heyd:—Because in this bill you make the deficiencies of one state a pattern for spreading all of this allotment over the whole forty-eight states and dependencies. My fundamental proposition is where the need is demonstrated.

Senator Wagner:—Very well, then, if this bill—I think it is based on need, but I am not going to argue that with you—suppose the bill is changed according to your suggestion now and, instead of only the head of the state coming, any subdivision of the state may come, isn't that what you suggested a moment ago?

Dr. Heyd:—No, sir, I would have nothing to do with this bill.

Senator Wagner:—Well, under any bill?

Dr. Heyd:—I didn't say that, and you can't read into my language anything like that. I said—

Senator Wagner (interposing):—I am asking you, suppose a bill is introduced which will provide for the central bureau here in Washington with a health commissioner at the head, with funds supplied by Congress, and with an authorization to give to states or political subdivisions according to the needs of those communities for medical aid. Would you then favor such a bill, Doctor?

Dr. Heyd:—When such a bill is introduced I should like to study it and discuss it with you; I will not sign a blank check.

Senator Wagner:—Well, of course that isn't centralization of power, is it, having a central bureau such as you recommend where the commissioner at the head has the right to determine whether a state should receive money or not?

Dr. Heyd:—It may have something of centralization in it.

Senator Wagner:—Well, isn't that bureaucratic?

Dr. Heyd:—No, the Post Office Department in Washington, that is centralization.

Senator Wagner:—I understood you to say that you were opposed to centralization.

Dr. Heyd:—I am opposed to the centralization that flows from this bill.

Senator Wagner:—Well, with all due respect to you, what you are suggesting is much greater centralization than the provisions of this bill suggests.

Dr. Heyd:—I don't believe so, Senator.

Senator Murray:—May I call his attention to this provision in here, on page 4, at the bottom of page 4, in connection with the grants to states:

> Provide for an advisory council or eouncils, composed of members of the professions and agencies, public and private, that furnish services under the state plan, and other persons informed on the need for, or provision of, maternal and child health services.

Under that section it depends on the profession, as a medical profession, and other public agencies, to determine the need for the assistance that is to go to the state. Wouldn't you favor that?

Dr. Heyd:—With all due deference to you, Mr. Chairman, those advisory councils have no power, it says "members of the profession." They might be a minority and in substance that section means that the advisory council would be rubber stamps.

Senator Murray:—Could that be corrected, then, if that is not satisfactory as it stands, could it be amended so as to make it feasible?

Dr. Heyd:—I don't believe you can amend this bill and make it workable.

Senator Wagner:—A moment ago you said something about the distribution of monies to Nevada?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Well, what was the purpose of that, to show they were getting more money than they should get?

Dr. Heyd:—No, the purpose of that was to show that the ordinary per capita expense of a well rounded health service is $1.32, and the money received for those two items from the Children's Bureau and the Public Health Service was $2.02, indicating in a relative way the element of the increased cost that grows from the filtering down of funds.

Senator Wagner:—Well, if that was so, you shouldn't be for any federal aid; if giving federal aid increases the expense of medical service, how do you justify your being for any federal aid?

Dr. Heyd:—Well, certain functions in medicine must be taken care of by the federal government.

Senator Wagner:—How do you know that that is a case where medical care was needed and an increased sum was needed to take care of the individuals in that state?

Dr. Heyd:—I am prepared to admit that it was needed or it probably would not have reached there.

Senator Wagner:—If you are prepared to admit that, then what was your point in citing it to us?

Dr. Heyd:—Because it heads the list of states that received this aid, in amount of money, and I can't imagine that the wants in child welfare and in maternal welfare can be greater in Oklahoma than in New York City, because they have less population, they have less babies born and they must have less crippled children, and yet they got more money.

Senator Wagner:—Did you examine these facts?

Dr. Heyd:—These are facts that have been supplied by these bureaus, sir.

Senator Wagner:—I mean, did you inquire as to what the need was in those particular instances?

Dr. Heyd:—No sir.

Senator Wagner:—Well, don't you think if you wanted to make a fair statement that you ought to have inquired whether that much money was needed to give proper medical care?

Dr. Heyd:—No, I see no reason to believe that those bureaus didn't give the required amount of money.

Senator Wagner:—Well, if they did, then it was a very desirable aid, wasn't it?

Dr. Heyd:—I presume it was.

Senator Wagner:—Well, you quoted it in criticism.

Dr. Heyd:—Yes, sir.

Senator Wagner:—And yet now you say it might very well have been needed.

Dr. Heyd:—Yes.

Senator Wagner:—Doctor, do you know the organization known as the National Committee to Uphold Constitutional Government?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Have you anything to do with that organization?

Dr. Heyd:—No, sir. What do you mean by "anything to do" with it?

Senator Wagner:—I will put it another way. I have a telegram, a copy of a telegram that you sent. I take it that you sent it to more than one individual?

Dr. Heyd:—Certainly.

Senator Wagner:—And in this telegram you say:

> Today's mail brings you from Sumner Gerard booklet "Political Medicine and You." Leaders of medicine convinced pending Wagner National Health Bill and supplementary bills being pressed various state legislatures harbor grave dangers impairing standard of medical profession, crippling research and threatening church and volunteer hospitals. Since this issue is being carried to every state we are convinced necessity nationwide educational campaign proposed booklet, page 22. Will you read and give support measured by importance of issue or if already supporting interest others.
>
> CHARLES GORDON HEYD,
> Past President American Medical Association.
> JOHN A. HARTWELL,
> Past President Academy of Medicine, N. Y.

That is signed by you?

Dr. Heyd:—Yes.

Senator Wagner:—To how many people did you send such a telegram, do you know?

Dr. Heyd:—I haven't the remotest idea.

Senator Wagner:—Well, you must have some idea, I can't accept your answer that you haven't the remotest idea.

Dr. Heyd:—I signed the master telegram that was sent out as a sampling, I think to fifty individuals in New York, and then it was probably extended, I don't know to how many, sir.

Senator Wagner:—It would be extended by whom?

Dr. Heyd:—By the Gannett organization.

Senator Wagner:—That is what I want to know; the Gannett organization sent these telegrams ostensibly signed by you?

Dr. Heyd:—Yes, sir.

Senator Wagner:—To all of the doctors alone or others too?

Dr. Heyd:—That I don't know; probably all types of people.

Senator Wagner:—This was sent to a bank.

Dr. Heyd:—It was sent to all the citizens.

Senator Wagner:—Did you supply that list?

Dr. Heyd:—No, sir.

Senator Wagner:—Did the Gannett organization supply the list?

Dr. Heyd:—If they had a list they certainly got it, because we did not supply it.

Senator Wagner:—Well, you said you originally sent out fifty and then there were any number more sent out after that?

Dr. Heyd:—I believe so.

Senator Wagner:—Well, aren't you a little more particular about the use of your name than not inquiring even as to who these telegrams were sent to?

Dr. Heyd:—No; I was quite prepared that that telegram go to every citizen in the United States.

Senator Wagner:—I see—to support the Gannett organization?

Dr. Heyd:—I have contributed to it.

Senator Wagner:—And you asked these people to contribute to it?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Do you know what their activities have been?

Dr. Heyd:—Only in a general way; I know the phase of the medical activities.

Senator Wagner:—You think it was all right for you as a doctor to associate yourself with propaganda of that character?

Dr. Heyd:—As a citizen, yes.

Senator Wagner:—Well, as a doctor?

Dr. Heyd:—As a doctor.

Senator Wagner:—You were talking some little while ago about the provisions in this bill which provide for payments for temporary disability and you said, as I understood you, and if I am wrong will you please correct me, that one of the reasons you opposed that is that one receiving some cash benefits because of loss of wages, that it would have the effect of continuing their unemployment and illness in order to receive the compensation, although the illness had disappeared. In effect was that what you said?

Dr. Heyd:—Experience demonstrates that that is correct, both in England and in Germany.

Senator Wagner:—Well, is it so with reference to workmen's compensation?

Dr. Heyd:—I think it is true of workmen's compensation.

Senator Wagner:—Well, do you know anything about the studies that have been made in New York State and other states.

Dr. Heyd:—Yes, sir, I went to Governor Lehman and had the doctors' committee appointed that framed the amendment to the workmen's compensation act of New York State.

Senator Wagner:—When was that?

Dr. Heyd:—In the previous term of Governor Lehman, when the amendment to the present workmen's compensation act was enacted. That is, I should say, about three or four years ago.

Senator Wagner:—Are you acquainted with any investigations that have been held in New York on that very subject?

Dr. Heyd:—Yes, sir.

Senator Wagner:—Don't you know that they show that there hasn't been any such experience in New York?

Dr. Heyd:—Since the enactment of the amendment it has been clear and clean, Senator, because the policing of the profession is stated in the amendment to the workmen's compensation as being the responsibility of the medical society of the county, but previous to the amendment the workmen's compensation was scandalous.

Senator Wagner:—Will you point out to me any investigation that shows that, do you mean the conduct of the doctors?

Dr. Heyd:—The conduct of the doctors, the conduct of the insurance chasers, the conduct of the auditors, of the insurance companies. Governor Lehman appointed this commission to study it, composed of five members of the New York Academy of Medicine and five from the Medical Society of the County of New York, and on the recommendations of that committee, the workmen's compensation act was amended, and since that amendment it has been cleaner.

Senator Wagner:—What is the nature of the amendment?

Dr. Heyd:—That is one of your bills, the original bill, I know. First the medical society was enjoined to prepare a detailed schedule and they worked with the insurance companies and devised a schedule which was fair and reasonable and within the compensation of the workman. Second, on disputed bills the bill must be passed by a tribunal of a county medical society. Third, there were double penalties if the insurance company stole a case, that is, if I saw a case and the insurance doctor came in and took the case away. And a lot of things that tended to purify the atmosphere surrounding the injuries to workmen.

Senator Wagner:—Well, are cash benefits now paid under workmen's compensation?

Dr. Heyd:—Yes, sir.

Senator Wagner:—And is medical service paid under workmen's compensation?

Dr. Heyd:—Yes, sir.

Senator Wagner:—And what portion of compensation is for medical service and what for cash payments?

Dr. Heyd:—I can't tell you that.

Senator Wagner:—Would you be surprised if I told you that about 90 per cent goes for medical services and 10 per cent for cash payments?

Dr. Heyd:—No, I would not be surprised, I would expect you to know.

Senator Wagner:—So that the medical profession is getting a real benefit out of the workmen's compensation?

Dr. Heyd:—The medical profession of the state of New York is eminently satisfied with the workmen's compensation in the state of New York.

Senator Wagner:—Well now, if that is so, I don't understand why the disability, which is the same theory except it is for an illness which was not acquired in the scope of employment, why wouldn't that work just the same as it does with the workmen's compensation law?

Dr. Heyd:—Well, there are a lot of reasons, Senator, why it wouldn't work as well. First, you have the control of the injured workman, he is working for a company, they know where he is, they know the manner of the injury, he selects his own doctor and he goes there, and all during that time there is the supervision by the company's doctor to prevent prolongation.

Now in contrast to that, in England and in Germany the prolongation of sickness beyond any reasonable time was so great that many times special agencies of the government had to be appointed to investigate this and to get rid of the malingering. There are a lot of very obvious psychologic factors in the two pictures.

Senator Wagner:—And you think we are not competent to prevent these prolongations?

Dr. Heyd:—Oh no, I am quite sure that the federal government can devise a means that is comparable to the workmen's compensation, but it is not in your bill.

Senator Wagner:—All right, will you suggest some provision that will strengthen that particular section of the bill?

Dr. Heyd:—I don't think you can amend the bill, Senator.

Senator Wagner:—Well, forget this particular bill.

Dr. Heyd:—I am not called on to write a bill, Senator.

Senator Wagner:—I see, that is your idea of public spirit?

Dr. Heyd:—I came down here in the spirit of public spirit.

Senator Wagner:—Simply to oppose?

Dr. Heyd:—Yes.

Senator Wagner:—Not to suggest, make any constructive suggestions?

Dr. Heyd:—May I put a question to you, Senator? Suppose I see a railroad train coming, where there is no bridge and a washout, am I going to start building a bridge or am I going to get a red flag and stop that train?

Senator Wagner:—That is not at all analogous. Dr. Heyd, do you know whether the medical journals contain any letters which criticize your action in sending this telegram, or your association with the so-called Gannett movement?

Dr. Heyd:—Yes, I know of half a dozen.

Senator Wagner:—May I read one of these letters?

Dr. Heyd:—By all means.

Senator Wagner:—This is to the Editor of Public Forum in New York *Medical Week:*

> In order to combat the Wagner Health Bill some of our physicians have formed the Physicians Committee for Free Enterprise in Medicine, a committee working with Gannett's National Committee to Uphold Constitutional Government.
>
> There may be some physicians in Manhattan, as there were in Brooklyn, who did not quite understand the function of the group they were joining. Therefore it is pertinent to point out some facts about the Gannett committeee.
>
> The activities of this committee are such that the Senate was impelled to question Gannett as to who the backers were. But this Gannett refused to divulge.
>
> The most interesting aspect of the committee is the fact that Gannett chose Dr. Edward A. Rumely to be its manager. This Rumely is none other than the "war-time pro-German propagandist who, with the aid of pro-Germans bought the New York *Evening Mail* for the purpose of presenting the Kaiser's cause. . . . He was convicted of trading with the enemy and sentenced to serve a year and a day in the federal penitentiary in Atlanta. (George Seldes, "Lords of the Press, page 211.)

Does any group in America which really wishes to maintain our constitutional democracy need the services of a man who was convicted as a spy? Are there no others whose motives are above suspicion? And it would be interesting to inquire whether Rumely's sympathies for the Kaiser's military machine have not grown apace with the development of Hitler's supermilitarism. One cannot escape the suspicion that a committee to uphold the constitution which needs the services of a former spy smacks of that patriotism which is the last refuge of a scoundrel.

The fact that outstanding men in the profession have joined the Gannett committee puts the whole profession in a very questionable light before the lay public. The opinions of these men are not representative of the profession as a whole, as was shown at the meeting of the Kings County Medical Society (reported in the New York *Times*, April 23, 1939), where a resolution condemning the Free Enterprise group was passed by a vote of ten to one. The fact that some of these men are officers of the New York County Medical Society puts the problem directly before the membership of that society.

I have mentioned the above facts about the Gannett committee on the chance that these officers were not acquainted with them. If, knowing them, the President, the President-elect, the Secretary and the Editor of *Medical Week*, among others, are still content to lend their support to a spy-run organization which refuses to divulge its financial backing, then it becomes incumbent on the membership to question whether these men are qualified to act as the official spokesmen for organized medicine. The choice is clearcut and should be an easy one for men of integrity to make.

MARTHA MENDELL, M.D.

201 West 16th Street.
April 23, 1939.

There are a number of others along the same lines, but I don't propose to read them. Do you remember reading that letter?

Dr. Heyd:—Yes, I know Dr. Mendell.

Senator Wagner:—Is it true that the Medical Society in Brooklyn took a vote on this proposition?

Dr. Heyd:—I think that is true.

Senator Wagner:—In favor of this legislation?

Dr. Heyd:—That I don't know.

Senator Wagner:—Was this vote ten to one as reported?

Dr. Heyd:—That I don't know.

Senator Wagner:—Well, there is just one other question. I don't want to pursue this indefinitely. You said something about research, of the bill possibly interfering with research. Of course I don't understand how it possibly can interfere with research, and in my opinion it encourages it, but one of the eminent doctors in New York came before this committee and stated that the National Health Department has done research work which is equal to the work of any private research laboratory, and he was a professor up at Columbia.

Dr. Heyd:—That is the National—

Senator Wagner (interposing):—The National Health Service, which is conducting research work constantly.

Dr. Heyd:—Has done research comparable to—

Senator Wagner (interposing):—To that of private institutions that conduct research.

Dr. Heyd:—I don't believe the body of facts would sustain that statement.

[Here there was an extensive discussion of the subsidizing of medical education.]

Dr. Cary:—Mr. Chairman, at this time may I enter in the record some information which I think the committee should have.

[Report entitled "Hospital Service in the United States, 1939," was filed with the committee.]

Dr. Cary:—At this time I have the pleasure of presenting the Editor of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION, Dr. Morris Fishbein, who will continue the discussion.

Senator Murray:—Dr. Fishbein.

STATEMENT OF DR. MORRIS FISHBEIN

Dr. Fishbein:—We have been presenting here, during the past two days, and on some previous occasions, the statements of men who have developed information concerning the medical point of view regarding the Wagner act. I do not wish to take the time of the committee to repeat either the arguments or the general statements that have already been made. I hope, rather, to cover ground that has not yet been covered or perhaps to correct some of the misstatements and misimpressions that have been made by some of those who have appeared previously.

I would call attention first to the fact that I have had opportunity in the past week and previously to read some of the recorded hearings that have already taken place. I believe it will be in the interest of bringing out the facts to mention some of the statements that have been made and to call attention to the differing point of view held by the representatives of the medical profession.

I would like first to point out that perhaps in a malicious, perhaps in a wholly humorous, manner the representatives of the medical profession who are sent by the American Medical Association are commonly referred to as a "hierarchy." It has been said by a previous witness at the hearing that the views represented by these men are just the views of this inner group and do not in any way represent the views of the vast majority of the doctors in the United States.

Senator Murray:—No one on this committee has referred to them as a hierarchy, or made any slurring remarks toward any member of the American Medical Association.

Dr. Fishbein:—With that statement, I will omit any further discussion of that point.

Senator Murray:—If a statement of that kind appears in the public press, we could not be held accountable.

Dr. Fishbein:—It appears in the record of the hearings.

Senator Ellender:—A witness so testified?

Dr. Fishbein:—Yes, Mr. Lee Pressman of the CIO.

Senator Murray:—Of course we could not be held responsible for statements made by a witness.

Dr. Fishbein:—No. I merely wished to correct the point of view that what we have had presented here is just the view of the officers who are here. The views which we have presented were adopted by the House of Delegates of the American Medical Association after a considerable number of hearings held by a Reference Committee before which there appeared scores of men.

Senator Ellender:—Doctor, I think some member of the Association testified yesterday that there were 130 some-odd members—

Dr. Fishbein:—113,113 physicians are members as of May 1, 1939, out of a total licensed to practice of approximately 170,000, of whom approximately 14,000 are over 65 and 145,000 actually in practice.

Senator Ellender:—Now the delegates met in St. Louis?

Dr. Fishbein:—Yes, sir.

Senator Ellender:—How are they selected?

Dr. Fishbein:—They are selected by the houses of delegates, the representative bodies of the individual state medical societies. These houses of delegates are in turn selected by the county medical societies which compose the individual state medical societies.

Senator Ellender:—How are the selections made from the states?

Dr. Fishbein:—They are made by nomination and election from the state medical society house of delegates.

Senator Ellender:—In what proportion to each state?

Dr. Fishbein:—The proportion is 168 delegates for 113,113 physicians. There were approximately 7,500 physicians in attendance.

Senator Ellender:—And the power to act, though, on any proposition that came before the Association, was in the hands of these delegates?

Dr. Fishbein:—Entirely in the hands of the House of Delegates, which determines policies and is the only body which can determine policy for the American Medical Association.

Senator Ellender:—Now some witness testified yesterday that hearings were held?

Dr. Fishbein:—Yes.

Senator Ellender:—Witnesses were produced before the House of Delegates?

Dr. Fishbein:—Yes.

Senator Ellender:—How many persons or doctors appeared in favor of the Wagner bill before your House of Delegates?

Dr. Fishbein:—Before the Reference Committee of the House of Delegates I would say that there were possibly five or six men who thought that, with suitable amendments, something might be done with the Wagner act.

Senator Ellender:—Who were those men, members, delegates, or were they members of the Association?

Dr. Fishbein:—Some of them were delegates, some were members of the Association and some were representatives of the hospital associations.

Senator Ellender:—How many were delegates?

Dr. Fishbein:—I would say not more than five of those who favored the Wagner act with amendments.

Senator Ellender:—Out of how many witnesses?

Dr. Fishbein:—Out of a score or more witnesses.

Senator Ellender:—Well, could you be a little more specific?

Dr. Fishbein:—I would be glad to send you a record of the hearings with the exact number of men and the men who made the statements and approximately what they said.

Senator Ellender:—I appreciate your offer, but we have so much to read now.

Dr. Fishbein:—My personal impression of the hearings which I attended—and at which I myself did not speak—was that those who were inclined to favor the Wagner act with amendments were the men in the House of Delegates who represented the state health officer group. The representatives of hospital groups and individual delegates who were not associated with state health departments were not inclined, in general, to favor the Wagner act with or without amendments.

Senator Ellender:—How did you come to classify them—

Dr. Fishbein (interposing):—They are known, of course. The members of the House of Delegates who happen to be state health officers are, of course, quite widely known.

Senator Ellender:—The selection, however, is made from back home?

Dr. Fishbein:—Yes.

Senator Ellender:—What proportion of the doctors do you think these five delegates represented throughout the entire membership?

Dr. Fishbein:—The five delegates who inclined to favor the bill with amendments?

Senator Ellender:—Yes.

Dr. Fishbein:—I would say somewhere between 5 and 10 thousand.

Senator Ellender:—What efforts were made by the House of Delegates to invite other witnesses to come in and testify?

Dr. Fishbein:—It is a rule that any one who has interesting material or evidence to present may appear and men did appear who were not even members of the Association.

Senator Ellender:—Was that widely advertised?

Dr. Fishbein:—It was announced in most of the newspapers of the United States, and certainly in the headlines of the newspapers in the city where the convention was being held.

Senator Ellender:—If five delegates were in favor of the bill as amended—in spite of that many—is the committee to understand that the delegates were unanimous in opposing the Wagner bill?

Dr. Fishbein:—When the vote was called for, the action of the Reference Committee as brought in to the House was adopted without a single dissenting vote.

Senator Ellender:—Was the vote tabulated or a viva voce vote?

Dr. Fishbein:—It was a viva voce vote, and no one said no. I will proceed, then, to a brief discussion of the possibility of amending the act.

At the Reference Committee the question was raised of the possible amending of the act or certain portions of the act in order to make it available to meet certain needs which I believe all of us recognize actually do exist. On that occasion representatives of the three hospital associations which lead in the United States, namely the Protestant Hospital Association, the Catholic Hospital Association and the American Hospital Association, spoke to the committee. The statement was made that each of these men had worked out fifty different amendments to the section dealing with hospitals alone, which might possibly make that begin to meet the needs that it was proposed to meet.

As we have considered the development of the Wagner act, it has appeared to us that there has been a relentless, persistent, almost a ruthless drive for the development of this legislation over a certain period of time. We trace this development from the beginning of the National Health Survey, which, as you know, was a house to house canvass of 750,000 urban and 50,000 rural families, made by 4,500 WPA workers under the direction of the United States Public Health Service.

Senator Wagner:—Doctor, you use a rather strong term, and I don't know that I was guilty of any such offense. I never intended to indulge in ruthlessness.

Dr. Fishbein:—I will endeavor to explain the term as I go along.

Senator Wagner:—I would like to have it explained now.

Dr. Fishbein:—We see a definite development of this legislation without any opportunity being given—although our services were frequently offered—to the medical profession, to consult with those who were developing the National Health Program, the National Health Conference and the bill itself, which grew out of the National Health Program.

Senator Wagner:—Well, Doctor, of course I am not acquainted with all of these activities you talk about, but a Dr. Booth from my own state appeared before this committee early and I think it was Senator Ellender that asked him if he wouldn't cooperate with the committee by suggesting amendments.

Dr. Fishbein:—You refer to this committee. I referred to the time of the drafting of the bill.

Senator Wagner:—Yes, I know.

Dr. Fishbein:—The committee has been more than kind in giving us full opportunity to present the point of view of the medical profession. This is the first occasion on which such an opportunity has actually been given.

Senator Wagner:—Well of course, this is the first occasion that we have had hearings on the bill. This is the time to cooperate.

Dr. Fishbein:—I refer largely to those who were concerned with the development of the National Health Program, the National Health Conference, the hearings on the National Health Program, after it was developed, and the time of the drafting of the bill. I have no objection whatever to saying again that I believe the fullest opportunity is now being given here to the medical profession as represented by the American Medical Association for the first time to express its point of view.

Senator Ellender:—Doctor, in that connection are you aware of the fact that many of the bills that are introduced and on which hearings are held you wouldn't recognize them after they got out of this committee?

Dr. Fishbein:—I am quite sure of that.

Senator Ellender:—Well, that, in a measure, is the purpose of these hearings, so we can get your ideas and if we can write them into this bill. That is what we desire to do, and that is why I emphasized to Dr. Booth, after he testified, and I think some of it is in the record, but I begged him to go to St. Louis and try to get the medical association to work with us, to try and offer some suggestions.

Dr. Fishbein:—That point of view was given the most serious consideration.

Senator Ellender:—So that the suggestion made to Dr. Booth was made to the Association—

Dr. Fishbein (interposing):—The possibility of amending the act was considered but the House of Delegates did not choose to believe that it was possible to amend this act to make it meet the needs that it is proposed to meet, and the general objectives which we all agree are desirable.

Senator Wagner:—By amending an act you can offer a completely new act, if you really desire legislation.

Dr. Fishbein:—It is quite possible that I shall recommend later the striking out of all of the act except the enacting clause and suggest certain other possibilities for meeting the needs.

Senator Ellender:—If you could do that, that is exactly what the committee would like to have you do. And will that have the O.K. of the Association?

Dr. Fishbein:—I will give you the action taken in regard to that when I come to it.

Senator Wagner:—I am not saying that I am going to support it, but I certainly will welcome the suggestions. And I may say this. This is not any breach of confidence. I spoke to Dr. Booth after the hearing and I asked him if he wouldn't impress on the American Medical Association—I know something about your activities and I suppose you are harder to convert than some others, but I am never hopeless about those things—and I asked him if he wouldn't say to the members of the Association that I am anxious to receive their cooperation and their advice and guidance in this matter, and he asked me whether he was authorized to say that, and said absolutely.

Dr. Fishbein:—May I say, Senator, we would have felt better if we had had opportunity at the time the bill was drafted to present some of these points.

Senator Wagner:—Well, the opportunity is here now.

Dr. Fishbein:—Yes, we are proceeding now from that.

Senator Murray:—Senator Wagner is not a member of our committee, so we have got an advantage over him here. We are going to handle this bill.

Dr. Fishbein:—That is very good!

Senator Murray:—I think we are getting to develop into a sort of a mutual admiration society here this morning.

Dr. Fishbein:—It is very simple to be pleasant.

Senator Murray:—I think we are getting along very nicely.

Dr. Fishbein:—I think so too.

Now one of the main objectives to which the American Medical Association representatives have referred in connection with the drafting of suitable legislation to meet the general objectives on which we are all agreed is the possibility of an attempt of a unified organization under the federal government for the handling of medical affairs, and integrating properly the care of the sick, preventive medicine, child welfare activities, industrial medicine and many other similar aspects of medical care, into a suitable arrangement.

I may say that when I first heard the words "Interdepartmental Committee to Coordinate Health and Welfare Activities of the United States Government" I was under the strange impression that it proposed to do what the title indicated, namely to draw together all of those activities of the government which were concerned primarily with the problems of medical care and of welfare as associated with medical care.

However, as we went along we discovered that that was not apparently the intention and is apparently not the expressed intention at the present time.

I would point out that the federal government now, in addition to the army and navy medical department, has innumerable departments which are greatly concerned with the problem of medical care, which by this act are still left to operate independently, to duplicate certain activities, to spend a good deal of unnecessary time and money and employ excessive personnel.

Now I will refer specifically to those departments. I would point out that the Children's Bureau, which is located in the Department of Labor, has both medical functions and other functions which are not strictly medical. Many of the functions thus concerned are also acted on to some extent by the United States Public Health Service and perhaps to some extent by other agencies which I will mention as I go along.

In the Department of Agriculture we have the Food and Drug Administration, whose problems as you know are largely medical in character.

In the Federal Trade Commission we have supervision over the claims made for various foods, drugs and similar products, used in relationship to medical service.

Also in the Department of Commerce there is a Bureau of Mines which is concerned with a certain number of medical functions.

In the Department of the Interior there is the care of the Indians, the control of two medical schools, the care of several institutions for the mentally defective.

In the Department of the Interior also there are certain educational functions which are, to some extent, medical in character.

In the United States Public Health Service, which is associated with the Department of the Treasury, there are certain functions which are wholly in the field of preventive medicine; other functions which are in the field of medical care. Then there is the control of narcotics, narcotic addiction, and the administration of two hospitals for that purpose, one of which is now located in Texas and the other in Kentucky.

In fact, there is no division of the government which does not now have certain medical functions. I believe the total expenditure on all of these functions, aside from the army and navy medical departments, amounts approximately to between $125,000,000 and $150,000,000 a year.

It occurred to us that an interdepartmental medical committee to coordinate these different departments under a single head, whether or not he is a member of the cabinet or one of the new types of secretaries to be created, is after all for the government to establish, but certainly unification of these functions might be of importance.

Now in addition, as you know, there have been created in recent years a considerable number of federal functions which are outside cabinet control, created as new divisions of the government. Therefore we have in the CCC a medical department, we have in the WPA a considerable amount of medical activities, we have the PWA concerned with the building of hospitals, and hospital construction has been active with government aid during the last few years.

I receive regularly from the PWA and the WPA and these other departments significant items of publicity having to do with the considerable amount of hospital building which they have aided in recent years, and the number of additional beds supplied through such agencies.

Senator Wagner:—You favor that?

Dr. Fishbein:—Yes, I think it is excellent. I propose later to refer to certain wastages of which I have personal knowledge. As a citizen I think these should have a little governmental investigation.

Under a certain branch of the government which has to do with the aiding of the rural areas there are now in existence in some twenty-eight or twenty-nine states plans for aiding people in rural districts to get complete medical care. Obviously that sort of function should be intimately associated with any government attempt to handle the problem of medical care. If I may, I will refer to an article in the *Saturday Evening Post* entitled "Rehearsal for State Medicine."

I could go on with other government functions, but I believe I have indicated the widespread—

Senator Ellender (interposing):—I wish you would go on with more of them, if you know of any. This is very interesting and I would like to probably "jine" some of them, as the darkies say.

Dr. Fishbein:—I could refer to the Coast Guard Service, which carries on a certain amount of first aid relief.

Now then, I concede that it would be the service of the Interdepartmental Committee to Coordinate the Health and Welfare Activities of the United States Government to bring this matter before the Congress of the United States as probably its first function. Obviously the creation of a suitable mechanism to handle medical care in the United States should depend on setting up an agency in which there would be an avoidance of duplication of effort and proper integration of each phase of the service under a single head. This would produce both economy and efficiency and a great deal of absence of the difficulty which is now involved in having to meet numbers of different governmental agencies in order to accomplish a single purpose.

Senator Ellender:—Would you be able to outline these various agencies that are now engaged in this work? You evidently have this worked out?

Dr. Fishbein:—We have a complete analysis for all the agencies of the government, and the appropriations made for each of them in different years.

Senator Ellender:—Can you furnish that to the committee?

Dr. Fishbein:—Yes, we would be glad to do that right away.

Senator Ellender:—It indicates the departments?

Dr. Fishbein:—The department, the amount of money spent, the nature of the medical service and many other facts that would be of great importance to this committee.

Senator Wagner:—Are you for putting them all together under one head?

Dr. Fishbein:—I believe it would be desirable to integrate the various medical functions of the government in a unified setup which would prevent duplication of effort, loss of efficiency and wastefulness.

Senator Wagner:—In other words, to sum up what you have just said, you do favor putting them all under one head, all that you have enumerated?

Dr. Fishbein:—Yes, within the possibilities of government, because I will now point out, and I hope to emphasize, the point that I am not a lawyer, primarily, and that while—

Senator Wagner (interposing):—Or a politician, are you?

Dr. Fishbein:—I hope not. I have never been accused of that.

Now as far as concerns the Constitution, I will say that the mechanism of fitting present activities, or future activities of the government into the Constitution is not my function.

The Interdepartmental Committee, on the basis of the National Health Survey, brought out what was called a National Health Program, which was a long range program planning for the development of the medical activities of the United States over the next ten years. At the time of the National Health Conference, I expressed the opinion that I did not consider it would be safe to plan a program of medical care for the United States for the next ten years on the basis of conditions as they exist today. With the amount of unemployment that exists today, with the amount of need that exists today, we have one concern; with the amount of employment and the amount of need that might exist ten years from today, we have another concern.

It is desirable to plan ahead, but frequently such planning turns out to be unfortunate. I remember attempting in 1918 to aid a distinguished committee to try to estimate the number of soldiers with nervous and mental disease, with cancer, with degenerative disease, and other conditions that would require care in all of the years from 1930 up to 1950. This was necessary in order to prospect a hospital building campaign for the future.

If we look back on the plans then projected in the light of conditions then existing and with our knowledge of medicine as it then existed, many of our estimates will have been found wholly away from the actual needs at the present time. I refer, for example, to the changes that may be brought about by the development of a new discovery that would relieve us of the care of a considerable number of persons with dementia paralytica, or the development of insulin, or the development of liver extract for pernicious anemia, or various new methods for the handling of cancer, or tuberculosis, which give us an entirely new picture after twenty years.

In this connection also I would like to refer briefly to the differences of scientific opinion that may exist in estimating a

so-called need. At present, for example, a distinguished officer of the United States Public Health Service has made addresses in various portions of the United States condemning to some extent the use of the tuberculin test as a means for determining whether or not a child has tuberculosis, or its relationship to tuberculosis. In the statement made by Mr. Homer Folks—

Senator Wagner (interposing):—You mean the x-ray test?

Dr. Fishbein:—Tuberculin test. In the statement made by Homer Folks, he was quite content to rely on the x-rays apparently alone. I know of no doctor in the United States who would rely on the x-rays alone in making a diagnosis for tuberculosis. I know of no authority in the United States at the present time, except perhaps this one authority in the United States Public Health Service, who is convinced that the tuberculin test might as well be discarded. That is a debatable point in medicine. And yet, presuming that this particular officer were to be put in charge of setting up the standard for determining needs in relationship to tuberculosis and the sole authority placed on him, he would find himself in a considerable disagreement with members of the medical profession who are generally recognized throughout the United States to be leaders in their field.

Senator Murray:—Doctor, it is apparent that you won't conclude your testimony for some time.

Dr. Fishbein:—Well, if you are interested in it, I can go on quite a while.

Senator Murray:—We are much interested, but we want to give you a full opportunity to tell us everything that you want to.

Dr. Fishbein:—I will be glad to come back after lunch.

Senator Murray:—We will recess now, then, until 1:30 and you can proceed at that time.

Friday, May 26—Afternoon

Senator Murray:—We will proceed with the hearing. You may resume, Doctor.

STATEMENT OF DR. MORRIS FISHBEIN (resumed)

Dr. Fishbein:—Mr. Chairman, at the time of the adjournment this morning I had reached a point in the development of the Interdepartmental Committee which led toward the National Health Program of the National Health Conference, and that in turn toward the development of the Wagner Health Bill. Now at the time of the National Health Conference a number of the representatives of the medical profession were present and had opportunity to speak. However, the time of that conference was the first opportunity that was available to the representatives of the medical profession to see the National Health Program. Obviously the time was hardly sufficient to examine carefully into the proposals that were made, or the evidence or data on which the proposals were based. Just as soon, however, as the National Health Conference adjourned the American Medical Association called a special session of its House of Delegates, the third such special session in the history of the organization, for the purpose of examining the National Health Program and adopting the point of view of the medical profession toward the National Health Program.

At the special session of the House of Delegates a considerable amount of evidence was presented, differing, to some extent, with the data that had been developed and offered by the National Health Survey, in relationship to the National Health Program. In addition a special committee was appointed by the House of Delegates to confer with the Interdepartmental Committee, and with its Technical Advisory Committee, relative to the proposals of the National Health Program. That committee met on two occasions, I believe, with the Interdepartmental Committee and had opportunity there to present some of its objections to certain portions of the program, and some objections with respect to some of the basic data and other considerations that were considered fundamental by the medical profession.

I mention this merely because, in the previous testimony presented here by Miss Josephine Roche, the point is made that nineteen such conferences were held by the Interdepartmental Committee between the time of the National Health Conferences and the sending of the National Health Program by the President of the United States to the Congress in January. A considerable amount of study and careful analysis of the National Health Program, as sent in January and as presented in July, reveals no significant change, modification or variation resulting from the nineteen conferences. Certainly none of the basic points brought out by the medical profession were introduced into the National Health Program as sent to the Congress by the President.

I would like to mention that the President of the United States himself did not urge immediate enactment of the National Health Program; that he recognized the report of the United States Public Health Service on the excellent health conditions in the United States during 1938, and that the President of the United States sent the National Health Program to the Congress with a recommendation for careful study, and that it is now with the Ways and Means Committee, I believe, of the House of Representatives.

Also, I would like to point out in this connection that obviously if an emergency existed the President might well have recommended, let us say, immediate enactment of some portions of the National Health Program; nevertheless, no such recommendation was made, and we had but a recommendation for careful study.

Another consideration which came before this committee concerned the proportion of the medical profession who favor the passage of the Wagner Health Bill. The statement was made that 1,500 pediatricians of the United States are behind the Wagner act. Now I know of no evidence, no data which would warrant such a statement. In fact I made particular inquiry of the Legislative Committee of the American Academy of Pediatrics, and of a considerable number of its members relative to the question as to what extent an effort had been made to find out exactly what the pediatricians thought of the Wagner Health Bill, and what number of pediatricians were behind the Wagner Health Bill, using the exact words which appear in the record. I am unable to find any evidence to substantiate that, and I am able to find a considerable amount of evidence differing from that point of view. That does not mean to say, however, that I am not of the opinion that many of the pediatricians of the medical profession would welcome certain types of aid to the development of a further preventive medicine program in relationship to child care or in relationship to extending the ability to feed infants properly in certain portions of the large cities or, in fact, in many other ways. However, there is nothing specific to be offered in that connection.

Another appearance before this committee had to do particularly with the problems of maternal mortality. I believe it will be important to the committee to have a little consideration—brief I hope to make it—having to do with the exact figures relating to maternal mortality in the United States. They are frequently compared to the disadvantage of the United States in all sorts of promotions that are planned to secure vastly increased funds in relationship to maternal mortality. Quite commonly the comparison is made with England, Ireland, Scotland and Wales, pointing out that the maternal mortality rates in the United States are worse than in England, Ireland, Scotland and Wales, or that the maternal mortality rates are worse than those of Sweden or of the Scandinavian countries. I would like to point out in this connection that the comparison is quite unfair. If you will take the rates in some of our better constituted states, as for example New York, Massachusetts, Michigan and Illinois, and compare them with England, Ireland, Scotland and Wales, we appear to have a considerable advantage in relationship to such comparison. A more interesting comparison, one better warranted, would be one which would take into account the fact that in the United States we have our frontiers within the country. Therefore a more reasonable comparison would be the United States as a whole with England, Ireland, Scotland, Wales and portions of South Africa and the Balkans. Such a comparison would give us a comparable situation and perhaps a more reasonable comparison as to maternal mortality rates.

Furthermore, I would like to point out that most of those who have appeared here before your committee in relationship to the question of the extent of maternal mortality work and the care of mothers in childbirth have been the obstetricians, representatives of the obstetrical specialty, who have given their full time to obstetrics in hospitals, and often particularly in maternity hospitals. While I am aware of the fact that there are conditions in our frontier areas in which maternal aid can be improved and much can be done for mothers in childbirth, it is not quite correct to accept the point of view of the obstetrician who has developed his entire technical knowledge in the hospital. I would like to point out, nevertheless, that the comparison I have just stated here was given to me by Dr. Joseph B. De Lee of the Chicago Lying-in Hospital, whose record in this matter is well recognized.

In other testimony which was offered here, I believe in Senator Wagner's personal appearance before the committee, particular emphasis was placed on certain facts in relationship

to two diseases, diphtheria and infantile paralysis. There was no tuberculosis in Detroit, the gentleman said, of any account. Senator Wagner said that he would produce later the authority whom he had consulted with regard to this matter.

It is generally well recognized in medical practice that the maintenance of a drive on a single disease is likely to result in almost any part of the country in a temporary lowering of the rates in relation to that disease. However, it is not possible to maintain such a drive on a single disease as a permanent effort. At such moments we put our entire effort against a single disease. I could point to the drive against diphtheria which took place in Chicago, or I could point to this drive against tuberculosis in Detroit and recognize that the chief value of such a drive is its educational effect on the community, calling the attention of the community for the time being particularly to that disease. But it is not possible to maintain such a drive. Frequently there is a reaction after the drive which takes you into a condition in which perhaps you are worse off than you were before the drive started. I think if anyone will look at the tuberculosis work in Detroit since the drive has stopped it will be discovered that even now it is not maintained at the level at which it was maintained during the time of the drive. With no amount of money would it be possible to maintain that particular kind of a drive permanently in any community. One of the chief reasons would be that such a drive would dislocate entirely the preventive medicine effort. By the extra effort put on a single disease one diminishes equally the effort against a considerable number of other diseases.

How do the figures compare before the drive and since the drive? With a condition like tuberculosis it is not safe to base figures on a matter of a year or two. But comparing the rates of the entire area over a long period of time with the rates of cities of comparable population it will not be found that such a drive has a permanent effect. It does have some value in educating the public. Such figures are susceptible to all sorts of analyses, as I believe Prof. Haven Emerson pointed out yesterday. Certainly that fact must be taken into account in relationship to the general trend downward of a considerable number of diseases at certain periods and a trend upward at other periods.

Again it has been said that a vast fund is of the greatest importance in attacking many of our disease problems. In the report on the National Health Program, much is made of the possibility of control of crippling diseases, and particularly infantile paralysis. I happen to be associated closely with the handling of more than a million dollars which has been collected in connection with the National Foundation for Infantile Paralysis. In recent meetings of the body of the organization charged with the dispensing of the funds, having a million dollars available to be disposed of in any manner that this committee might wish, the committee having practically supreme authority over the disposition of this one million dollars, it was exceedingly difficult to find a way to spend $100,000 efficiently and successfully in encouraging research in infantile paralysis. Having a million dollars, it was difficult to find a legitimate number of research projects warranting the prompt expenditure of $100,000 by men capable of doing good research work. Making an allotment is not the primary consideration in the development of an attack on disease. Knowledge is the first consideration, and knowledge can be accumulated only in relationship to the possibility of having men capable of doing research under conditions where good research work can be done, and in addition to that having material on which to work. For example, if we had an infantile paralysis epidemic extending over large areas of the United States we could do a lot more research on infantile paralysis than we are able to do. It is the tendency of the disease to disappear during the cold weather and then to break out anew during warm weather. Unless we have cases in which to make tests and studies it is extremely difficult to make studies.

Let us consider the question of the provision of hospitals. As I mentioned this morning, there has been no lack of hospital construction, no lack of the additional building and provision of new beds in recent years. We have seen a considerable number of hospital projects being carried out on a scale much beyond and at a rate much beyond what we had five or ten years ago. I believe the senator from Louisiana is acquainted with the great hospital which is now being constructed in New Orleans, providing a great number of new beds. I recently visited Richmond, Va., where a thirteen-story hospital is now being built, largely with public funds, and where I was informed three other additional hospitals are contemplated, and the funds are apparently being sought. I have seen one hospital to which I wish to refer in this connection, namely the hospital which was built in Hot Springs, N. M., costing $2,000,000, with the provision of ninety beds for crippled children. The town has 300 people and is approximately 185 miles from any place.

Senator Wagner:—You did not mention these hospitals, of course, in criticism of their construction?

Dr. Fishbein:—I am about to criticize the one in New Mexico, not the other two, the new one in Richmond or the new one in New Orleans. I am criticizing the one in New Mexico as an example of the fact that abuses may arise in relation to the building of certain of these hospitals. Obviously the one in New Orleans was a necessity. In fact, if I may digress at this point, I think I may have had something to do with aiding and encouraging the building of the hospital in New Orleans. I came to New Orleans sometime ago and discovered four Negroes using one bed in a city-managed institution. I saw to it that it got proper publicity in the press. That intensified, to some extent, the drive for sufficient hospital facilities.

Now then the hospital in New Mexico to which I referred has ninety beds for crippled children. When the time came to man the hospital it was discovered that no accredited orthopedic surgeon was available in New Mexico for the job. Therefore, by special action of the legislature an orthopedic surgeon was employed from El Paso, Texas, at a pay said to be $7,200 a year to ride 185 miles into New Mexico once a week to do the necessary surgery. The rest of the time the hospital was under the management of a resident who was developing himself as a specialist in the field of orthopedics.

A population of a certain size can develop only a certain number of cripples. That fact must be taken into account. With a population of a certain size you develop a certain number of cripples; that is, unless an epidemic of crippling disease breaks out. Now after its establishment the hospital is actually in difficulties and it will not have a sufficient number of cripples to use the facilities. It was built particularly for that purpose. Already it is a matter of concern, both to the people of New Mexico and to the country generally, and of all physicians interested in these matters, as to what is to be done with this hospital. If you will estimate the cost you will discover that it cost $22,200 a bed for a building and equipping, whereas it is possible to build a good hospital today at a cost of $5,000 a bed.

Senator Murray:—Who built it?

Dr. Fishbein:—It was built partially on federal funds and partially on state funds.

Senator Murray:—At what cost?

Dr. Fishbein:—$2,000,000.

Senator Murray:—Couldn't it be converted into a general hospital, used for other purposes?

Dr. Fishbein:—I will say, from correspondence that I have available, there is evidence that that is a matter which is worrying particularly the senators from New Mexico.

Senator Wagner:—Doctor, how were the funds obtained? Wasn't there a proper showing made in order to be able to make the money available?

Dr. Fishbein:—I believe that that would be a matter of suitable inquiry. I believe that there is a custom that those who obtain money are supposed to show a need, and that having shown this need certain money dispensing agencies are authorized to grant the funds for that purpose. I know of no other method of obtaining money in Washington except through that technic.

Senator Wagner:—Was that money obtained from the WPA or the PWA?

Dr. Fishbein:—I have not checked into that particularly. I merely know the hospital is a crippled children's hospital built with state and federal funds.

Senator Wagner:—At a cost of $2,000,000?

Dr. Fishbein:—At a cost of $2,000,000 for building and equipment.

Senator Wagner:—Do you know what proportion was contributed by the government?

Dr. Fishbein:—I can investigate and supply that, if you wish to have the figures.

Senator Murray:—Go ahead, Doctor.

Dr. Fishbein:—Now the suggestion was made, incidentally, from two different sources: One, that this be developed as an institution for the tuberculous, the other that it be developed for the care of children convalescent from rheumatic fever. The latter suggestion would be obviously impossible, because it would not be considered a good atmosphere, or a good temperature to which to ship children with rheumatic fever.

At one point the National Health Program recommends additional funds in relationship to rheumatic fever for the removal of a considerable number of tonsils and adenoids.

Senator Wagner:—What would be the greatest benefit in counteracting the disease?

Dr. Fishbein:—It would be in restoring the patients to working condition. Here again is a case in which the medical profession, speaking as experts in relationship to the condition called "rheumatic fever," would be inclined to express doubt. So many of the points have to do with the need and the manner in which the need is to be determined that we must recognize the fact that there can be differences of opinion among physicians, and well qualified physicians, as to these matters of need. Any simple mechanism which leaves the decision in the hands of one or two persons is a matter for special consideration. I am inclined to believe that there ought to be enough people and enough of a cooperative effort between the state and federal agency concerned so that there would be no question as to an actual scientific determination of need. I do not believe the Wagner act suitably protects the people or the money of the United States in relationship to that determination.

Senator Wagner:—Have you any suggestion as to how to make that effective?

Dr. Fishbein:—I have, Senator. I believe it must be much more regulated than is provided in your measure, and that it would certainly involve the development of competent scientific evidence in the determination of need, based on the experience of recognized experts whose opinions would be given weight and value, and which might not be discarded at the behest of a single individual.

Senator Wagner:—Doctor, I take it you are acquainted with title VI of the Social Security Act?

Dr. Fishbein:—I believe that much good has been done in relationship to some of the use of money that is given to the United States Public Health Service to meet certain needs, yes, sir.

Senator Wagner:—That is similar to the provisions of this act?

Dr. Fishbein:—Yes. I believe also that a careful scrutiny in relationship to the practicability of those projects should be made by the scientific investigators, who would study and make a careful resurvey of the exact manner of use. This would reveal wastage in some instances.

Senator Wagner:—Is that surmise or do you know that that is so?

Dr. Fishbein:—Well, that is based largely on the statements that are sent to a periodical of the type of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION by physicians in various parts of the country who venture their criticism. I am not willing to accept such criticism on the statement of one physician who writes. I believe that, if the federal government were interested in resurveying directly the manner of disposition of money and meeting certain needs in relationship to preventive medicine, occasionally it could be found that the money was not employed with the greatest of efficiency.

Senator Wagner:—That is a matter of examination?

Dr. Fishbein:—Yes.

Senator Wagner:—As to the general method involved, as to the aim in making grants in aid?
